 Ale, the pint o', 464
 Allamanda, treatment of weak, 53; in pots, to manage, 194; Schottii, 194
 Allotment Farming—November, 64; December, 148; January, 247; February, 327; March, 407; April, 506
 Allotments, rules for their establishment, 204
 Alpina nutans not flowering, 472
 Alstromerias, list of, 142, 160; dying down, 194
 Amaryllis, culture at Claremont, 60; list of, 161; reticulata, 221; to discern from a lily, 303; culture, 332; Atamasco and formosissima culture, 393
 American garden, to construct, 271
 Animals, notes about, 469
 Anomatheca cruenta and juncea, 240
 Antholyza, list of species, 203
 Annuals, rules for sowing, 134; sowing in turf, 491
 Apis muscorum, 89
 Apples, list of, for espaliers, 33; Beauty of Kent, 36; list of dessert, 157; descriptive list of kitchen, 176; gathering, 294; list of, 314; annual imports, 357, 397; in Derbyshire, 394
 Approaches, to form, 296
 Apricot as a standard, 72; pruning, time for, 194; diseased, 234; cause of decay, 317
 Aralia japonica, 82
 Araucaria Bidwilliana, 499
 Arbor vitæ sowing, 354
 Arches over walks, 20
 Asparagus, beds, making, 325; forced, 421
 Attachment, singular, 313
 Auricula, soil for, 363; spring treatment of, 284; autumn and winter culture, 306; its winter treatment, 323; its properties, 342; diseases, 343; list of, 343
 Australia, plants for, 20
 Azalea japonica, 142; sowing, 353; indica culture, 441
 Azara integrifolia culture, 284
 BABIANAS, their culture, 203
 Bacon Hopper, 252, 354
 Balsam cuttings, 52; sowing, 374; culture, 442; sowing for July, 431
 Bank, sloping, for fruit, 94; plants for a green, 233; plants for river, 234
 Barnardia scilloides, its culture, 203
 Barrenwort, 55
 Bath and West of England Agricultural Show, 413
 Beans, culture of, 385
 Beatonia, species of, 203
 Beautiful, influence of, the 221
 Bedding-out plants, 26; distances for, 134
 Bedding plants and bulbs, 20; white, 374
 Bees: honey harvest, 15; new mode of managing, 15, 53; particulars of twelve stocks, 16; drones seen late, 33; honey season in Northumberland, 48; confining, 49; wild, Apis lapidaria, 51; Calendars—November, 66; December, 150; January, 248; February, 328; April, 507; ventilation, 66; north aspect for, 66; dividing hive for obtaining artificial swarms, 66; Taylor's notes on, 66; Golding's improved hive, 73; age of young broods, 73; wild, 89, 112; harvest of 1852, 93; honey-harvest on moors, 110; swarming with young queen, 153; management, 173; in Taylor's hive, 174; using old comb, 174; notes on, 192, 252; honey harvest in Lincolnshire, 213; destroying royal cells, 214; feeding and hives, 248; necessity for feeding, 269; in boxes, 353; feeding, early breeding, cleaning floorboards, snow, recipe for barley-sugar, 409; excess of drones, 491; entrance to Taylor's hive, 492; artificial swarms, 430
 Bee-boxes, 449; with the comb broken down, 452
 Begonia parviflora hybrid, 17; Evansiana, wintering, 105; hybrid, 123; winter blooming and culture, 304; Thuaitesii and culture, 415; sowing, 471
 Bell-glasses, 496
 Belts of trees, 474
 Berberis vulgaris, 21
 Bessera, list of species, 204
 Bignonia radicans, treatment, 53; radicans major not thriving, 193
 Birds, familiarity of, 19
 Blandfordias, list of and culture, 204
 Boleti, list of eatable, 169
 Bomareas, list of and culture, 240
 Borders, arrangement of, and list of plants, 345
 Botanical terms explained, 452
 Bouquet in Covent-Garden, 78, 99; model, 158; d'amour, 313; price of, 341
 Brava geminiflora, 241
 Brodiaeas, list of and culture, 241
 Brunsvigias, 242; list of and culture, 260
 Buds and bulbs, on the possibility of combining, 375
 Bulbine, 301
 Bulbs, hardy and half-hardy, their culture, 140, 160, 203, 240, 260, 301, 319, 361, 399, 438, 477; for large beds, 173; leaves, 451
 Bullfinch diseased, 114
 CABBAGE, culture of Thousand-headed, 33; tribe, notes on, 46; protecting, 243; culture, 328, 386; weevil, 359
 Cabbage-worts, their value, 65
 Cactus culture, 472
 Calceolaria seed, sowing, 52; list of yellow, 152; for bedding in shades, 412, 471; culture, 459; compost, 431
 Calendar for November, 73; December, 153; January, 253; February, 333; March, 413; April, 510
 Californian agriculture and horticulture, 373
 Calliphurria Hartwegiana, 302
 Callithauma, species and culture, 302
 Calochortus, species and culture, 302
 Calostemmas, list of and culture, 319
 Calthorpe's (Lord) small garden tenants, 158
 Camellia buds falling, 94; turned brown, 252
 Campanula Carpaticas flowering, 113
 Camposema rubicunda, 1
 Canna, wintering, 105
 Cantua dependens culture, 8; injured by heat, 33
 Cape Jasmine not flowering, 152
 Cape of Good Hope wines, 318
 Carnation soil, 73; layering, 194; culture of perpetual, 205
 Carpodotes, its culture, 320
 Carpolyza spiralis, 320
 Carrot failure, 234; culture on unsuitable soil, 463; sowing, 506
 Cassia corymbosa as a standard, 145
 Castuses when resting, 194
 Cattleya guttata, 220; mossiæ, culture, 233; pallida, 500
 Cauliflowers, wintering, 46, 63
 Ceanothus rigidus culture, 9, 275; azureus, 33, 92; in Devonshire, 275; list of and culture, 281, 422
 Celery blight, 94; best kinds, 134; coal-ashes as a preservative of, 185; cause of decay, 234; and its cultivation, 484
 Celsia Cretica, 94
 Cereus (night-blowing) in greenhouse, 52
 Chaffinch's familiarity, 19
 Cheese dairying, 138
 Chelidoniums, 473
 Cherries in Derbyshire, 394
 Chilworth's (Rev. J. L.) residence, 103
 Chiswick Shows in 1853, 138
 Chlidanthus fragrans culture, 320
 Choretis, list of and culture, 320
 Chrysanthemum forcing, 20; Pomponé Hendersonii, 82; time of flowering, 122; culture, 223; list of, 243
 Cider-making in Herefordshire, 291; sweet, making, 488
 Cinchona Calisaya, and culture, 493
 Cinchonads, how known from Madderworts, 75
 Cinerarias mildewed, 20; sowing, 73, 460; blooming in November, 152; blooming in March, 294; amelloides, propagating, 412; compost, 431
 Claremont, visit to, 59
 Clanthus puniceus, wintering, 204, 314; in room, 234
 Climate, vicissitudes in our, 486
 Climbers, a purple autumn, 33; for greenhouse, 72; list of tender, 173; in stove, 332; hardy, 393; for high wall, 413; combination of, 423
 Clivia nobilis culture, 320
 Coburgias, list of and culture, 320
 Cochlearia acaulis, 83, 342
 Cockle beds, 72
 Cockscomb culture, 442
 Collanias, and their culture, 361
 Colocordium culture, 302
 Commelina scabra, and culture, 35; wintering, 105
 Conantheras, and their culture, 361
 Coniferae, 86, 125, 164, 206, 244, 285, 324, 365, 403, 443, 482; at Finedon Park, 106; sowing Himalayah, 253; planting, 431
 Conifers, time for planting, 33
 Conservative walls, their use, 224
 Conservatory, heating a small, 134
 Cooperias, and their culture, 361
 Coreopsis filifolia, 83
 Cornelian cherry, as a fruit, 59
 Coronillas, list of, 422
 Correas, list of, 422
 Cosmos bipinnata, 83
 Cottage garden and its November crop, 48
 Cottagers, prizes for, at Shows, 106; a chapter for, 385
 Couch grass, its impoverishing power, 467
 Country Gentleman's Companion, 152
 Courteen Hall Gardens, 144
 Couve tronchuda, 492
 Covent-Garden notes, 2, 23, 36, 56, 77, 99, 117, 136, 157, 176, 198, 216, 236, 257, 298, 316, 337, 359, 378, 398, 417, 435, 456, 475, 495; fraudulent measures at, 278; cut flowers at, 341
 Cows, oat straw for, 214; turnips required for, 214; murrain in, 432
 Crab stocks, grafting, 114
 Crinum, and their culture, 361
 Crystal palaces, Rivers's, 18
 Cucumber house, 73; pit and its management, 187; forcing, 234; early, in dung-bed, 239; removing male blossoms, 253; culture, 412; useful sorts, 432
 Cumingia, species and culture, 399
 Cunninghamia sinensis, 9
 Cupressus, various species, 9; list of species, 45; Govenii in bloom, 458
 Cuttings, how to strike, 152; bottom-heat for, 354
 Cyanella, species and culture, 400
 Cyclamen, leaves decaying, 173; lost their leaves, 393
 Cyclobothra, species and culture, 400
 Cypella, species and culture, 401
 Cypripedium soil, 492
 Cyrtanthus, species and hybrids, 401; list of species, 438
 Cytisus filipes, 422
 DACRYDIUMS, list of, 86
 Dahlias, seedlings for 1853, 29; house-sewage for, 114; of 1851, 186, 290
 Dammaras, list of, 87

- Damp, what is, 194; walls, to cure, 234
 Damsons, 93; wine, fining, 333
 Danish Isles, sixteen months in, 119; abundance of fruit there, 119
 Dantzic, a visit to, 428
 Daphnes, a few of the best, 167; *indica rubra*, 221; list of, 422
Datura just blooming, 19; requires shelter, 113; sanguinea in the open border, 221; in room, 234
 Daubenyas, 439
 Decay, its increase in plants, 338
 Decorative planting, 473
 Decoy pond and its water-fowl, 190
 De la Pre, 106
Dendrobium nobile Blandianum, 500
 Dessert, fruits for winter, 259
Deutzia gracilis and *scabra* culture, 8
 Dewing, its meaning and mode of applying, 402
 Dianellas, 439
 Dibble for wheat, 233
Dichorisandra, 82
Diplacus puniceus, 422
 Double-glazing and a well as protectors from frost, 455
 Draining, 65, 497, 505
 Drain, to construct, 134
 Drimias, 439
 Dryandras, list of, 423
 Dung-beds, construction of for forcing, 286
- EARLY life of Poor Man's well-wisher, 272, 450
Echeandia ternifolia, 439
Echeveria rosea, 421
 Edgings, 108; Hogg's, 258
Edwardsia grandiflora seedling, 214, 333, 423
 Eisenbeck (Professor Von), 118, 158
 Elder juice frauds, 36
Elisene longipetala culture, 439
 Elm, the *fastigiata*, 452
Epimedium Alpinum, 55
Eranthemum, 305
Erica bicolor, with pale flowers, 73; *Banksia* dropping its buds, 152
Eriobotrya japonica, 423
Erythrina crista-galli propagating, 20, 423
Escallonia macrantha culture, 9, 423
 Espalier rail, 234
Eucalyptus, 423
Euchilus obovatus culture, 263
Eucomis culture, 440
Eucrosia bicolor, 440
Euphorbia jacquiniiflora, for wreaths, 59, 305
Eutaxia myrtifolia culture, 262
 Everlasting flowers mingled with grasses, 223
 Exhibitors of flowers, their tricks, 418
- FAIRY-RINGS explained, 469
 Fault (A) among us, 287
 Feathers, different markings described, 387; their varieties, Pencilled, 406; the Laced, 465
 Ferns, moving hardy, 54; fogging off, 94; Moore's labels for, 99; shoots, cooking, 314, 354
 Ferrarias, 440
 Finedon Park, 106
 Fish diseased, 472
 Fitzroya wood, 493
 Flax thrashing, 492
 Flower-beds, plans to be given, 20; a new one, 60; new mode of trying colours in, 471
 Flower-buds, to distinguish double and single, 33
 Flower-garden plans, (No. 1) 67, 73, 113, (No. 2) 147, (No. 3) 289, 393, 427
 Flower-markets, London, 212
 Flowers, general competition with, 218; coloured everlasting, 471
 Forcing, preparations for early, 101; notes on, 238; operations of the season, 286; its general principles, 300
 Forest Trees of Great Britain, 355
 Forests (Royal), their mismanagement, 379
 Forsaken Heritage (The), 13
Forsythia viridissima pruning, 394, 423
Forsyth MSS., 3, 36, 77, 98, 146, 357, 377, 417
 Fourcroyas, 440
 Frenelas, list of, 87
 Fruit, stores, managing, 38; and vegetable culture combined, 80; influence of soil on, 313; growing, its commercial importance, 395; how to secure a crop, 419
 Fruits, Belgian Commission on, 300
 Fruit-trees, general planting of, 137; on walls, their distances, 152; for north walls, 152; renovation of, 178, 218; for Cumberland, 294; after the mild winter, 318; grass-walk over roots, 333
 Fuchsias, list of good, 32; *spectabilis*, 33, 114; with a single stem, 52; wintering, 53, 105; list of and culture, 92; list of best, 132; straggling, 152; *Fuchsia* bed, to make, 174; culture, 249, 460; budding, 294; cordata, 342; *serratifolia* culture, 412
 Fumigating greenhouse, 54; injury from, 471
 Fungi, British eatable, 14; eatable, 109, 169; British, 189, 348; useful kinds, 312
Funkia subcordata, 17; *grandiflora alba*, 27
- GALAXIAS, 440
 Gardeners and their masters, 22; who are impostors, 257
 Gardenias for walls, 461
 Garden-orchard, 80
 Garden, restoring an old, 424, 431
 Gardens, benefits of exhibiting them, 222
 Gardiner (W.), proposed biography of, 118
 Gas, heating by, 433
 Gastromomas and their culture, 477
Gaura Lindheimeri, 26
Geissomeria aurantiaca, 420
 Geissorhizas and their culture, 478
 Gelasine and Gethyllis, 478
 Geraniums, moving into greenhouse, 20; propagating Golden-chain, 20; wintering scarlet, 33; wintering, 53, 104, 471; (Scarlet), Amazon and others, 102; cuttings of Unique, 113; as standards, 144; turning yellow, 151; unpruned, 234; (Commander-in-Chief) as a bedder, 273; management of scarlet, 354; gangrened, 354; treatment of seedling, 304; for forcing (Queen of February), 457
Gesnera Zebrina, culture, 52, 103, 205; elongata culture, 304; *Suttonii alba*, mealy bug on, 314
 Gladioli, notes on species, 174
Gladiolus gandavensis, planting out, 194; culture, 479
 Glasgow, garden near, 53; Floral Exhibition, 418
Glaucium luteum, 375; *corniculatum*, 395
 Glazing, double, 20; laps in, 20; its benefits, 55; to remedy drip, 94
 Gloxinias not bulbing, 33; management, 173; list of and culture, 252; from leaves, 376
 Gold fish in vases, 450
 Goosander, red breasted, its habits, 37
 Grafting on upper side of branches, 252; in a hotbed, 482
 Grapes, preserving, 20; Black *Barbarossa*, 84, 499; growing late, 124; caterpillars on berries, 134; diseased, 174; the Fox, as a stock, 180; forcing, good specimens of, 233; cause of their shanking, 381, 428; the *Trebiana*, 477; *Esperione* and others, 500
 Grasses as ornaments, 223
 Greasing the wheel, 166
 Greenhouse construction, 20; stages, 59; plants for back wall, 72; trellis plants, 84, 94; and vinery, 114, 363, 382; with west aspect, 114; facing the north, 214; plants, winter-blooming, 282; vines and flowers in, 294; arranging a new, 294; heating, 333, 387; climbers, 374; modes of heating small, 422, 430; in March, jottings for, 459; work there, in March, 440
Grindelia grandiflora, 115
 Guano, its composition and value, 176
 Guernsey Lily cone flowering, 273
Guzmania tricolor, 83
- HABRANTHUS and their culture, 479
Habrothamnus elegans and *fasciculatus* culture, 282
 Haemony, what is it? 114
 Hardenbergias, list of and culture, 84; mono-phylla treatment, 234
 Haricot bean, a large white, 174
 Heath cuttings, management of, 354; propagating and growing, 412
 Heat, how to retain, 415
 Heating, easy mode of, 387; economical mode of, 410; by gas, 413; a small greenhouse, 433; modes of, 501
Hedychium Gardnerianum, 471
 Hellebores, winter-flowering, 421
 Herbaceous plants, list of, 27
 Hickory nuts, sowing, 33
Hippeastrum alicium platypetalum culture, 342
Hippophae rhamnoides, 174
 Hives (Taylor's), 294
Hoarea melanantha, 17
 Hollyhocks, list of, 33, 53
 Honey harvest of 1852, 372
 Horticultural and Pomological Association, 399, 452, 470
 Horticultural Society's Meetings, 81, 122, 220, 341, 420, 457, 498
 Horticultural Society, rules for a Provincial, 265; *Peebleshire*, 266; of London first suggested, 358; its first formation, 377; in Tipperary, 477
 Hotbed, a shallow, 17; its duration if shallow, 152; for early forcing, 366; its construction and management, 480
 Hothouse, law of removing, 314
- Hot water in bottles to exclude frost, 430
 Hot-water *versus* Polmaise, 245
 Hyacinths in pots, 294; with many offsets, 471; deformed, 510
 Hybrid between sheep and deer, 470; between pheasant and fowl, 470, 472
Hydrangea culture, 413
- ICE, preserving, 214
 "I have no one to take care of me," 407
 Indian seeds, 173; corn, 499
Indigofera decora pruning, 353
 Insects, Stephens' Collection, 496
 Ipomeas, to keep free from red spider, 194
 Iris (China) culture, 54
 Irrigating with sewage, 153
 Ivy keeping walls dry, 252; pruning and propagating, 354; against a wooden fence, 491
Ixias, propagating, 53; culture at Claremont, 61
- JACKDAW's familiarity, 19
 Japan Lilies for garden decoration, 508
Jasminum, dwarfs, 61; *sambac*, management of, 194
 Jones, William and Ann, 88
 Junipers, list of, 126
Juniperus, list of species, 164, 206
Justicia speciosa culture, 304
- KEARSLEY House, 63
Kennedy, list of and culture, 84
 Kidney beans, new varieties tried, 100; forcing, 239
 Kitchen-garden crops, 328; routine, 367, 385, 408; crops, arranging economically, 504
- LABELS for Roses, 234; cheap, 386

METEOLOGY OF THE WEEK.—At Chiswick, from observations during the last twenty-five years, the average highest and lowest temperatures of these days are 61° and 43° respectively. The greatest heat, 75°, occurred on the 13th in 1845; and the lowest cold, 26°, on the 13th in 1850. During the period 84 days were fine, and on 91 rain fell.

RUBY-FLOWERED CAMPTOSEMA.

(*Camptosema rubicunda.*)

PLANTS of this comparatively new genus have been likened to, and called, Kennedias, in gardens. In their outward appearance, and in their general habit, they much resemble some of the species of Kennedyia, Zichya, and Hardenbergia, yet, when they are examined botanically, they exhibit a wide departure from that group, and come nearer to Canavallias and Diocleas. The genus was founded by Hooker and Arnott, and the name derived from *kamptos*, bent, and *sema*, a standard, alluding to the form of the

flower branches. Instead of *Papilionaceæ*, as formerly, all the pea-flowering, and all plants, whether with pea-flowers or not, that bear their seeds in pea or bean-like pods, as the Acacias, are now called Leguminous plants, because such pods, in the language of botany, are called *legumes*; and to get rid of the old associations about pea-flowers, or *papilionaceæ*, leguminous plants are now called *Fabaceæ*, or Beanworts. This species of *Camptosema* is a native of Brazil—a very gay climber, with ruby-coloured, pea-like flowers hanging down in long racemes, and producing a fine effect. It requires the heat of a stove to make the most of it, but a warm conservatory will probably be found sufficient for it. It was first introduced to the German gardens four or five years ago, under the name of *Kennedyia splendens*. *Leaflets* smooth, milky-green beneath; *racemes* of flowers about nine inches long, drooping; *calyx* with two small bractes at the base, somewhat two-lipped, and from 4 to 6 lobed; *petals* nearly equal, deep ruby-red in colour, the largest rather bent back, clawed with two blunt teeth at the base of the lamina; other petals clawed, each with two blunt teeth at the base of the lamina. It is in the Diadelphia Decandria of Linnæus. The *stamens* are in two groups, nine and one.—*Botanical Mag.*, 4608.

Culture and Propagation.—From what I have learnt about this new fine climber, I have no doubt but that it will succeed well where the *Beaumontia grandiflora* and *Stephanotis floribunda* thrive and flower. It is true the latter will do just as well in the Calcutta orchid-house, the common stove, the early vinery, and the warm conservatory; but the *Beaumontia* will not do in either heat nor cold—that is, in a stove or in a greenhouse—but in a place intermediate between the two; and such intermediate temperature, I am quite sure, is best for this *Camptosema*; and, being a strong grower, it must have sufficient head-room to extend itself freely before it will flower much. Cuttings from small side shoots is the nursery way of propagation, but, for private use, make layers of long shoots of last year, in the spring, and so get full-grown plants at once. D. BEATON.

No one better than an Editor knows the impossibility of acting so as to please everybody, and even in enlarging our paper, at a certain expenditure of several hundreds of pounds, and with a total uncertainty as to any remunerative return, we are quite sure of displeasing some of our readers. We shall regret the displeasure of even one of them, but conscious of the soundness of our intentions, we hope all things, and pursue our way. That way has been known for four years to our readers, and we can assure them that “the old path” will not be diverted, but only widened. We have felt that for some time, Poultry, and other intelligence, though strictly within our original purpose, have trespassed upon space that should be devoted to Gardening, yet, Poultry, Bees, the Aviary, and Farming, are subjects on which a large proportion of our subscribers demand from us information. Then, again, we have been asked not to print advertisements so that

these must be bound up in the volume; whilst other, and very numerous, parties have required, that to these advertisements we should give additional space.

We are also fully conscious of the truth of an opinion expressed in a recent number of *The Quarterly Review*, that the contents of our little work are as suitable for the cottage of gentility, with double coach-house, as that usually tenanted by the labourer; but while we admit thus much, we well know it is, and has been successfully, our aim to write so as to be clear and useful to all. We have the best of all evidence, that the man of education, as well as the self-taught labourer, are satisfied with our pages; and although we shall so far meet the criticism of our Quarterly contemporary as to add to our present title that of THE COUNTRY GENTLEMAN'S COMPANION, and while it will be our continued study to cultivate the good will of that important class, we shall still pursue our course unaltered, still study to

be THE COTTAGE GARDENER, but with its usefulness again increased. In testimony of this, and we have other new stores of information placed at our disposal, we offer the present number as the best of evidence.

IN our last number we stated our conviction that the days of the Potato are not yet brought to a close, but that we look forward with confidence to a recurrence of that state of health in the plant, when unmurained crops will be usual, and murrained crops rare. We stated, also, our reasons for thus hoping, and one of those reasons is, that, even in the worst murrained of years, we find many instances of crops entirely exempt from the disease. This exemption is not of rare occurrence, and though the circumstances occasioning such exemption are not with certainty known, yet the exemption demonstrates that such circumstances exist. If they exist, they can be ascertained; and, when ascertained, the days of safety to the potato will be restored.

One such instance of exemption has been communicated to us by one of the best practical horticulturists we know—Mr. Weaver, gardener to the Warden of Winchester College. He says—"Early this spring I received thirteen very handsome potatoes from a gentleman of this neighbourhood, who is fond of having good potatoes at his table every day. They are called the *Dalmahoy Seedling*, being raised by Lord Morton's steward, at his lordship's seat, Dalmahoy, near Edinburgh. They were all very sizeable—from 3 inches to 3½ inches, the widest way of them—and I determined to plant them whole. But where could I plant them? was the next question, as nearly every inch of our ground was under crop at the time. At last, finding a small plot alongside some globe artichokes, a line being set down about five feet wide from the artichokes, here I planted the sets, two feet six inches from set to set in the row. This was done on the 13th of March. The row stood clear of everything excepting a few weeds; the plants were not earthed up at all, and I believe nothing was ever done to them from the time they were planted until they were taken up about the middle of August. On taking up the first root, seeing the tubers so numerous, induced me to count them. The following is the number found at each root:—58, 62, 47, 33, 54, 41, 45, 48, 29, 30, 32, 57, 47. I took them up myself, and, I believe, every one of them: the sample very fine for the season. After they were taken up about six or eight days, they were looked over, and all diseased ones removed, which was nearly one-third of the bulk. This has been found the case in all our general crops that were in the ground so late as the middle of August.

"One kind, which we call the *Herefordshire Early Purple*, is a kind which we generally begin taking up for use about the second week in July, having done so for many years. Wanting the quarter for another purpose, these were all taken up by the 20th of the month, and stored away in the potato house, where most of them are at this time. In these we have not seen a

diseased potato at all this season, from the first to the present time.

"Another favourite, called *Heigh's Norbury Seedling*, a beautiful potato, allied to *Walnut-leaved Kidney*, and a great bearer, was taken up on the 1st of August, and scarcely any diseased ones have been found among these from first to last. The same observation applies to *Rylott's Flourball*—scarcely any diseased, and taken up at the same time. *Luker's Oxonian*, taken up at the same time, nearly one-third diseased. *Forty-folds*, about four bushels of which were taken up at this time, were much more free from disease than those which remained in the ground to the middle of August. Among these last taken up, full one-third were diseased. And in a quarter of *York Regents*, which were somewhat shaded by trees, upwards of two-thirds were diseased."

We may add, that Mr. Weaver entirely coincides with us in recommending planting none but early kinds, planting whole sets, and planting early.

COVENT GARDEN.

THERE were many fine gardens in London once; but what Mr. Dickens calls "The Great Invasion" has so squeezed and circumscribed them, that, yielding to "the pressure from without," there is nothing left of them now but their names. We can imagine in our own minds what these old gardens were like, with their trim hedges, clipped "greens," and "allies artly devised in the same;" to say nothing of "the proper knots," as flower-beds, which would have supplied, with credit, designs for any "Knitting, Netting, and Crochet Book," even of the present day. We can imagine, too, what the old gardeners were like, with their long beards, Elizabethan ruffles, and high conical hats. These are what some people call "the good old times;" but they have all passed and gone, and with them the good old gardens, and the good old gardeners, of London, leaving scarcely even a trace of where this one "grafted all sortes of trees," or that other practised "the right ordering of all delectable and rare flowers."

The only place of this kind, bearing the name and aspect of what it once was, is COVENT-GARDEN; and, as if unwilling to be banished from their former haunts, it would seem as if the ghosts of these old times still met and held their midnight revels there—for during the time that mortals sleep, there are produced, in this once fertile spot, such fruits, and flowers, and esculent plants, as would excite the incredulity of those who have not seen them. It would astonish some of our country friends who have never witnessed such a sight as is there exhibited every Tuesday, Thursday, and Saturday morning, to see the ponderous cabbages, the unmeasurable carrots, the enormous celery, the gigantic rhubarb, the snowy turnips, and the curly parsley! produced as if by fairy power, or coming from, we hardly know where.

It is of COVENT-GARDEN that we intend weekly to furnish the readers of THE COTTAGE GARDENER with a report. Our object shall be to notice everything as it

comes into season, with such comments and remarks on the most important productions as we conceive will be interesting. In this way they will have a sort of calendar of horticultural produce, as well as a good indication of what to grow and what to avoid. These ghosts of whom we have spoken know well, and none know better, what is worth growing, and what suits best the taste of this great world of London.

During the past week there has been an abundant supply of all kinds of fruit. APPLES are very plentiful, and range in price from 3s. to 8s. per bushel. *Fearn's Pippin* has made its appearance as gay and ruddy as ever; this is much grown by the market-gardeners of London, for, besides being a good market apple, it is a great bearer, and its fine, brisk, and sugary flavour render it suitable either for dessert or kitchen use. *Golden Pippins* and *Ribstons* are "in," and there are still a few *Kerry Pippins* left, but they are very small and very shrivelly. PEARS vary from 3s. 6d. to 7s. 6d. per half-sieve,* and are also very plentiful; besides a number of nondescript varieties, there are several of the best sorts already in perfection. *Williams' Bon Chrétien* are going out; they are getting very yellow and very "sleepy;" these have been very plentiful this season, more so than that respectable individual, "the oldest inhabitant," ever remembers. *Hessle*, not *Hazel* nor *Hessel*, has also furnished a large supply, but is going out, and giving way to the *Autumn Bergamot*, *Beurré Capiaumont*, and *Marie Louise*; as these will be in season for some time to come, we shall have an opportunity of commenting on them on a future occasion. There are some very fine *Gansel's Bergamots*, from Guernsey, for which the epicure must give from 3s. to 5s. per dozen. The *Jersey Gratioli* has also appeared during the week; this is a most delicious pear, but very little known: everybody who wishes to plant six trees should have this one of them; we shall speak of it again. *Louise Bonne of Jersey* has been in for some time; this also is a very fine and very beautiful autumn pear, which ought to be in every collection; it may be said to come in between the *Williams' Bon Chrétien*, *Jersey Gratioli*, and *Marie Louise*. PLUMS of inferior baking kinds, such as *Muscle*, and other hedge varieties, are plentiful still, at about 2s. 6d. to 3s. the half-sieve. *Damsons* are also very plentiful, at the same prices. Among the dessert varieties, *Coe's Golden Drop*, and some small shrivelled *Greengages* are all that are to be seen. Of PEACHES, the *Late Admirable*, and a few *Catherines*, are making their appearance; but we would rather have a good *Jersey Gratioli*, or *Marie Louise* pear, than all the *Catherine* or other late peaches the garden can produce. GRAPES, both home and foreign, are plentiful. *Black Hamburgs* constitute the former, and fetch according to quality and colouring, from 2s. to 5s. per pound. The foreign are from 9d. to 1s. per pound.

Many fruits which are merely enumerated in the present notice, shall be treated of at length, as we have occasion to refer to them in subsequent reports. H.

* Half-a-Sieve contains three-and-a-half gallons.

FORSYTH MSS.

IN our last notice of LIEUTENANT PATERSON (vol. viii. page 378), he was at Norfolk Island, in the May of 1792, and there, and at Port Jackson, he continued until nearly the close of the century, but before that he had become Captain, in the New South Wales Corps. He then returned home, but did not remain there long, for under the date of February 22nd, 1800, and from Port Jackson, there is this letter from

MRS. PATERSON TO MR. FORSYTH.

We arrived here on the 4th November, after a tolerable speedy voyage of less than five months, which was a fortunate circumstance for us, as the ship was excessively uncomfortable, and ill calculated for passengers, and besides very leaky. We put into St. Salvador, on the coast of South America, to refit, from which place, until we arrived here, we had constant gales and bad weather. In one of these severe storms Col. P. was nearly killed by a fall in the cabin, being very much bruised, and three of his ribs broken. He is now, thank God, quite recovered, and has been lately exploring the banks of the river Hawkesbury, principally for coal, which was not found just at the spot where he expected; but there is plenty in other situations. He was amply rewarded, however, for his trouble, by discovering many new plants, and in visiting the different settlers in that neighbourhood. The crops of grain those farms produce are wonderful, but, notwithstanding the fine country and climate, the colony is in a most wretched state, from bad management. An active, able man, is much wanted here, as Governor, and that soon, or I fear it will take a long time to bring it about again. I send this letter by Mr. Cover, one of the unfortunate missionaries sent out in the Duff. He is a worthy man, and can give a correct idea of this place, having been here above twelvemonths. He will also be able to give you every information respecting that unsuccessful mission. The cultivation of the vine in this country is very much neglected, from the two or three last seasons having failed. Fruit-trees, particularly apricots and peaches, thrive uncommonly well, especially the latter, which in general produces fruit the second year from the stone. Col. P. would have written to you himself, but is very much engaged in arranging regimental business to send home.—E. PATERSON.

He returned to the colony not only as Colonel of his regiment, but as Lieutenant-Governor, and continued to retain that office until his final retirement. His last letter among these manuscripts is dated from Sidney, October 13th, 1800.

COLONEL PATERSON TO MR. FORSYTH.

Governor Hunter being about to quit this country gives me an opportunity of saying that both Mrs. P. and myself are in good health.

Since my arrival in this country I have had very little time to pursue my favourite amusement, what with the duty of the corps, and the constant watch we are obliged to keep over the United Irishmen that have been lately sent to this colony. We have discovered several plans that were in great forwardness to subvert the government, and to put every one to death that would not join them.

On a committee (to investigate the business), of which I was one, it clearly appeared that their plan was to have seized on a detachment of soldiers doing duty at Panamatta, in the time of Divine Service, and to have attacked us at head-quarters. We fortunately discovered their diabolical intentions the day before it was to have been attempted, and, from their observing our preparations, they did not assemble; but we found several of their ringleaders. Some of them have been punished, and a party of them sent to Norfolk Island.

There are three of our officers that return to England by this conveyance; one of them, Captain Johnston, is a prisoner under my arrest. As Governor Hunter would not allow a court-martial to try him in this country, the evidences are taken on oath, and sent to the commander-in-

chief. I shall be anxious to know the result. From all these circumstances you will easily conceive that my situation in this country is not very pleasant.

He retired from New South Wales in the spring of 1810, and among the deaths recorded in that year, we find this entry. "June 21st. At sea, on board His Majesty's ship *Dromedary*, Colonel William Paterson, Lieutenant-colonel of the 102nd regiment, F.R.S., Member of the Asiatic Society, and many years Lieutenant-Governor of New South Wales, from which colony he was returning to England in the command of the 102nd Regiment."

The following is a list of the *Horticultural and Poultry Shows* of which we are at present aware. We shall be obliged by any of our readers sending us additions to the list, and giving the address of the Secretaries.

HORTICULTURAL SHOWS.

- BURY ST. EDMUNDS, Nov. 26 (Chrysanthemums). (*Sec.* G. P. Clay, Esq.)
 CALEDONIAN (Inverleith Row), Edinburgh, Dec. 2.
 HAMPSHIRE, Nov. 18 (Winchester). (*Sec.* Rev. F. Wickham, Winchester.)
 LONDON FLORICULTURAL (Exeter Hall, Strand), Oct. 12+, Nov. 9+, 23, Dec. 14+.
 NORTH LONDON, Nov. 23, Chrysanthemum.
 SOUTH LONDON (ROYAL), Oct. 14+, Nov. 11+, Dec. 9+, 16.

POULTRY SHOWS.

- BIRMINGHAM AND MIDLAND COUNTIES, 14th, 15th, 16th, and 17th December.
 BRISTOL AGRICULTURAL, December 7th, 8th, and 9th. (*Sec.* James Marmont.)
 CORNWALL (PENZANCE), about a week after the Birmingham. (*Secs.* Rev. W. W. Winfield, Gulval Vicarage, and E. H. Rodd, Esq.)
 DORCHESTER, Nov. 18th. (*Sec.*, G. J. Andrews, Esq., Dorchester.)

† For seedlings only.

PINE-CULTURE: THE HAMILTONIAN MODE.

WE have, during the last few months, received so many queries, or heard inquiries about Pine-culture, from persons of moderate means, who wish to indulge occasionally in that luxury, and occasionally to make the fruit, by sale, pay the expenses incurred, that we think it will be but an act of justice to take up the subject in a step-by-step way; the dryness, or tedium, necessarily attending this course in the eyes of the experienced, will, we hope, be excused for the sake of the class alluded to. Too much generalisation befits not persons of this caste; they want the very alphabet of culture itself; and to make ourselves useful, we must, to use an apposite saying, "begin at the beginning."

As much confusion has continually arisen from a jumbling together the pot and the open-soil modes, we must, in this series of papers, confine ourselves to the open-soil, or Hamiltonian mode of culture, believing it to be the very best of all for the amateur; being the easiest to learn, on account of its extreme simplicity, and requiring so small an amount of labour and attention. It is somewhat fortunate that the subject should force itself at this period upon us, when, of all others, perhaps, the least advice is required in other affairs.

STRUCTURE FOR PINE-CULTURE.—We come here to the consideration of the form, the angle, or roof pitch, the glass, the interior fittings, &c., each of which will be handled in due course. Having much faith in our

friend Hamilton, whose long experience in this matter, to say nothing of his being the originator of this system, highly qualifies him to offer advice, we have written to him on the subject, in order to see if he is prepared, by subsequent experience, to confirm what he had previously laid down in his useful book. He has most kindly and fully answered the inquiries we had to make, and also permitted the use of his name, if necessary.

Mr. Hamilton has, within these four or five years, built a new house for his pine system; and it will be well to give a detail of its character. It is a span-roofed structure, running east and west, thus presenting a south roof and a north one. The pitch of the roof is three-and-a-half inches to the foot, the length of the house fifty feet, and the breadth fifteen feet. There is a walk up the centre, beneath the ridge, of two feet in width; a bed of five feet on either side, and a trench, or cavity, eighteen inches, front and back, for the piping. This house holds one hundred plants, and, according to friend Hamilton, each plant ought to produce one full-sized fruit annually, of some five to seven or eight pounds—to fix a weight for the purpose of enabling our readers to form a calculation. Of course, it will be understood, that whilst the weight here assumed would be too much for such as the Queen section, so, in like manner, will it be below the standard for such as the Providences, Envilles, Cayennes, &c.;—thus much to obtain a clear view of the question. To return to the digressive point—the external character and dimensions of a house proper for this system—we come now to the mode of heating. "Each bed," says Mr. H., "would require two pipes, in order to equalize the heat at the roots of the pines; two would be far better than one of greater calibre, for it is not a high concentration of heat at one point that is requisite, but a steady and given amount equally diffused. Moreover, it will be seen, that in hot-water heating, although a circulation *may be* established in one pipe or tank, yet it would be necessarily sluggish; and a return pipe to the boiler ensures a lively circulation, in addition to the end in view—the equalization of the bottom warmth."

Thus much for bottom or ground-heat; now for atmospheric warmth, for which *special* piping is requisite. Mr. H. says there should be two pipes back, and two in front, that is to say, a flow and a return belonging to it. It will here be seen what value is to be attached to the idea of growing pines out-of-doors, in Britain, like so many artichokes. When such is well accomplished, rents will assuredly rise, for some thousands of acres will be needed for vineyards and pine-gardens, for the demand for both will be enormous.

Thus it will be seen, that eight parallel lines of piping are considered requisite by Mr. Hamilton in such a house, and if pines are to be grown in the highest degree of perfection of which they are capable at any season, we join in Mr. H.'s opinion. The beginner in pine-culture must here observe, that the pipes to heat the soil are no more than an equivalent for the loss of tan, or other fermenting material, so that such may be fairly left out of the question of expense; for although, in the event of tan-yards being close at hand, the bottom-heat from that source might be obtained at a cheaper rate, yet, when the extra labour and uncertainty are taken into consideration, a certain loss in the end may be counted on. When tan has to be drawn half-a-dozen miles, we consider the proceeding most preposterous, according to the old adage, "penny wise and pound foolish;" those, however, who do not care about winter-pines, but would rest content with a good lot of such as Queens, Providences, and Envilles, from June to October, may succeed with one-half of the piping for warming the air of the house. The bottom-heat piping, nevertheless, the same as before stated.

To return to Mr. H., he says, "my boiler is at one

end of the house, in the centre, and outside. Immediately opposite to it inside, I have a reservoir, or iron pan, of about two feet in depth, by half-a-yard square, and this has six pipes attached to it." It will be here seen that the reservoir is but a centre, common to all the pipes, which all take their flow here, and here deliver their return. This, we suppose, is partly to save the expense of what are termed elbow-joints, and other complex affairs. In this description we are not quite sure that we understand Mr. H.; if, however, any error should creep in, we shall soon get it rectified. Mr. H.'s words are these, "the reservoir will require six pipes attached to it, so that the pipes which heat the air of the house can be plugged or stopped at any time, when only bottom-heat is requisite. This answers much better than valves." We saw Mr. H.'s house about twelvemonths since, and witnessed his thus turning off the flow, which he did in an instant, by merely thrusting a roll of coarse cloth into the advance pipe.

Having thus far followed Mr. Hamilton's plans pretty closely, we may be allowed a few comments as we proceed. In the first place, it does seem matter of astonishment, that a practice so simple, and consequently economical, so much in accordance with the habits of the pine, as stamped in indelible marks by nature's own impress, should not before this have become more general. What said Pope?

"Truths would you teach, and save a sinking land,
All hear, none heed you, and few understand."

And so it has ever been with inventions which carry a great amount of simplicity in the face of them; they pass unheeded by the majority of minds for want of the appearance of that degree of elaborateness, which, in fact, is the bane, instead of the true merit of most inventions. In speaking thus, we do not wish it to be inferred that the Hamiltonian mode ought to supersede all others; by no means. There are cases in which the pot mode may be more desirable, inasmuch as the pines may, with facility, be removed to a cool room in the pot, when necessary to retard them for particular purposes; and, indeed, it is still a question whether the Hamiltonian mode is equally applicable to all kinds; that it suits the Black Jamaica, or what is termed Montserrat by some, is undeniable. This pine, at least, seems quite at home under this treatment; and as a pine for general use, and especially for winter, it will be long, we think, before it is superseded; albeit, the rising popularity of the Cayennes threatens hard. We may here offer an opinion about the form of the house, which, indeed, is the first thing to begin with. Mr. H., it has been seen, is an advocate for span-roof houses, running east and west. Now, we really do not see why this mode should hold such a strong position in the minds of our practical men. "Speak well of the bridge that carries you safe over," is a trite maxim, and doubtless will apply to the case in hand; but a too stiff adherence to established modes is but too apt to assume a pertinacious character, and to prove a barrier to progression, which, in the most unmistakable manner, is the order of the day. Why not north and south? Pines, it is said, occasionally enjoy a little shading for three or four hours during bright and hot days, and the mid-day sun can very well be dispensed with on such occasions. But to build span-roofs with a southern facing, is to set a trap to catch all the mid-day rays possible. Sir Joseph Paxton, breaking through the trammels of prescription long since, shewed by his ridge-and-furrow-roof that there were more ways than one of building houses. The ridge-and-furrow of course is simply a multiple of the span-roof, with an eastern and western slope, or in other words, a morning and an evening side. Now, if it can be shown that a half-day's sunshine will suffice for pines, whether that half-day be an eight to twelve o'clock affair, or a twelve to four o'clock, why the rest of the question

would seem to follow as matter of course. We have talked over this subject with several first-rate men at various times within the last half-dozen years, and have almost invariably found them with a latent desire to break from southern slopes, "willing to wound but afraid to strike." Not every one, however, who can conceive a project carrying promise of advance, has the power to shew forth his conceptions in real bricks and glass.

To sum up, then, as far as the roof question is concerned, we may be permitted to offer our impression, which is, that it appears tolerably certain that the southern slope may be departed from in the case of pines, and exchanged for a morning and evening side, as in a span running north and south, as to its longitudinal direction, or, indeed, to some other points of the compass, as the case may be; and that much latitude may be fairly given in this respect, the pinery giving up a point occasionally to existing circumstances, perhaps as an adjunct to the villa or to other structures.

But if a span-roof running east and west *must* be adopted, we think that some little change in the modification of the interior fittings might be resorted to with advantage. For instance, it is a matter of principle that an equality of light should be enjoyed by the pines; those on the north side of the walk should have an equal chance in that respect with those on the south bed. To effect this, the bed on which they stand must necessarily be somewhat higher. Admitting, then, a span-roof perfectly equal in dimensions as to the exterior, we would have the back bed half-a-yard, or nearly so, higher than the front, or, if you please, the front bed half-a-yard lower; all this amounts to the same thing. In such a case, the first and ruling principle would be, to pay a due regard to the ordinary ground level outside; the front bed should be so placed as to present every portion of the foliage to the solar rays, even in the depth of winter. This done, the lower the whole structure was sunk below the ordinary ground level the better, according to our ideas; inasmuch, as the farther this point is carried out, the more the structure would prove self-protecting—a great matter in economising fuel; and every gardener knows that the use of fuel in the dull winter months, or, indeed, at any period, is a necessary evil, to give it a hard name. But not only is a proper economy involved in this arrangement, but the very health of the pines.

There is still another consideration as to the roof question; and, as we are simply throwing out hints for the consideration of those about to embark in pine-culture as a profitable investment, it will be well, perhaps, to offer suggestions with freedom, and to make our comments keep pace with the order of the subject. In pursuance of this, then, we would say, if a span-roof, running east and west—are both sides of the span obliged to be equal? In thus widening the question, we shall give a free scope to a full examination of the whole subject. As the south front is too apt to admit of too great an amount of the solar rays, why not make it less in width, say as two to three? Many other remarks might be offered on the character of the roof, but as they interfere too much with the line of our subject, we must postpone them until we can offer a chapter on roofs. The structure, then, should be so far sunk below the level, as that the front sill of the sashes is but above that level; other parts will follow as matter of course. As to glass, Mr. H. has omitted to mention it in his correspondence; but before closing this subject, we will take care to ascertain this, which, with anything else that may arise, together with omissions, &c., will be introduced at the conclusion. It seems probable, in the event the house having an east and a west roof, that the British sheet would be most eligible; and as to a south and north roof, rough plate on the south, and

sheet on the north; however, we have no experience of the rough plate.

As an encouragement to those about to venture on the Hamiltonian system, it may be observed, that Mr. H. has had it in operation for many years. At first, in a poor, low, contracted, and rough-looking house, which, without the noble pines it contained, would have been but a sorry affair. Such, however, was his success, that his employer empowered him to build a handsome new house to his own liking, and here the system may be seen duly carried out. We now give an extract, in concluding *this paper*, from Mr. H.'s letter now on the table: "The gardener of H. Marsland, Esq., of Woodbanks, is going by my instructions. He has three plants of the Montserrats (?) with three fruits each, and there is every probability of the nine fruits weighing thirty-three pounds." R. ERRINGTON.

(To be continued.)

YUCCAS.

In these days of plant-growing, for fame, for gold or silver medals, or for hard cash, such old plants as Adam's needle, and the like of it, that are thought beyond the art of the specimen grower, are left to nature, or rather are taken from her care, and then turned adrift to take care of themselves as best they may. *Yuccas* will grow or live in any kind of soil, if it is not too wet, and when one flowers any thing beyond the common run, it is reported in the periodicals as something strange, like the flowering of the American Aloe, as it is called, and no one turns his attention to the improvement of the race, or, if he does, he thinks there is little merit in saying much about it. Hence it is, that if you wish to flower a *Yucca*, and would learn the easiest and best way to go about it, you may look through all the authors, from Phillip Miller to the last number of *THE COTTAGE GARDENER*, and not be much the wiser. Indeed, I do not remember a single author who has given a full account of the propagation and cultivation of *Yuccas* as a class, except Mr. Gordon, of the Horticultural Society's Garden, at Turnham Green, and that was seven years ago (*Gardeners' Chronicle*, 1845, p. 384). Since that time, Mr. Gordon has so far improved on his own recorded practice, that his success surprised me the other day on looking over the garden. Like most other gardeners, I never dreamed that *Yuccas* are as susceptible of improvement, at the present day, as the Pine-apple plant was twenty years ago; but so it is, without any shadow of a doubt, and not only that, but it may be so managed as to become a regular competitor on the exhibition tables.

As far as I can make out, we have only one instance on record, in which a *Yucca* was exhibited in a pot for a prize, and that was in Fifeshire, in Scotland, some years ago. The flower-stem of this plant rose seven feet from the pot; the plant was exhibited in September, and was only struck from a cutting the March before. We know that some people run away with an idea that the *Yucca*, and the American Aloe, flower only once in a hundred years; others are as far wrong, who assert that a *Yucca* will flower regularly every year, after it once comes to a flowering age. The opinions about this age are also as far from the truth as the rest of the story. Some will tell you that five or seven years will bring it into a flowering state; others say ten years; whilst a third says fifteen, and a fourth goes as far as twenty. All this is in black and white, in my own library; but there is a *Yucca* in the next parish to me, Long Ditton, which did not flower for twenty-five years after being planted, and it might have been two or three years old at the time. It is now in bloom for the third time, and there were just five years between each time of flowering.

The truth is, however, that the flowering of *Yuccas* depends on soil and situation, rather than on certain or uncertain dates.

Yucca gloriosa is the one we hear most about, and this plant is a native of the sea-shore, in the southern states of North America, and although it lives with us in almost any soil or situation that is not absolutely wet, it prefers the sea-coast, a full southern aspect sheltered from all other points, the best friable loam, and a rock, or chalky bottom perfectly dry. In such situations in Devonshire, Cornwall, the Isle of Wight, and the South of Ireland, it blooms every year as well as it does in Virginia or South Carolina.

At its full age, it is not proof against those very severe winters we sometimes experience in this country. For instance, the great celebrated tree *Yuccas*, in the Oxford Botanic Garden, with stems five feet high, clear of leaves, and which Mr. Baxter, the no-less-celebrated curator, successfully transplanted, were cut down to the ground by the frost of the winter of 1837—38, but they sprang again from the roots, while plants of four or five kinds of them, not nearly so large or ripe, as we may say, stood out in Kilkenny without any protection whatever. It has been observed, that more *Yuccas* flowered with us in the hot summer of 1826 than in any one season before or since. In that year, a *Yucca gloriosa superba*, the best variety, with the purple on the back of the petals, flowered for the first time, after being twelve years planted, and two years when planted in a nursery at Windsor. The top of the flower-stem was twelve feet six inches from the ground; the flower-stem itself being upwards of nine feet; out of this stalk grew forty-seven side branches, eighteen inches and upwards in length, and each produced from twenty to thirty flowers, or probably 1,100 flowers in the whole. Who would not envy so noble a specimen of this much-neglected plant. "But stop a while"—another individual of the same species, whose girth, at fifteen inches from the ground, was 25½ inches, produced six flower-spikes at the same time, on which was counted in one day no less than 2,704 flowers. But the most splendid specimen of *Yucca* on record, under cultivation, is a plant, or rather tree, of the Aloe-leaved species, of which the Countess Dunraven sent a drawing to Mr. Loudon, from the gardens at Adare, in Ireland. This drawing is given in many of Loudon's works; in the *Vegetable Kingdom* of Dr. Lindley; and in other works here and on the continent. This *Yucca* was twenty-eight feet high; at ten feet from the ground the trunk girted seventeen inches, and at twenty feet it divided into "six massy branches, each terminating in a pyramid of flowers." Notwithstanding such instances, a *Yucca gloriosa* that is from three to five feet high in the stem and leaf, with a flower-stem of about equal dimension, would be a very fair specimen to pride oneself on, after a few years cultivation, on the principle advised by *THE COTTAGE GARDENER*.

It is very strange that no writer has sufficiently admired the *Yuccas* as fit plants to introduce into geometric flower-gardens, for which they are admirably suited, when reared with the sole view of that kind of furnishing; and no less so, that some of our great architects—Sir Charles Barry, for instance—have never thought of them as architectural plants, as one may say, instead of the great aloes which Sir Charles, at any rate, is so fond of for rearing up on pillars and corners in his elaborate designs. I could name more than one place in which Sir Charles Barry introduced, not only an aloe or two, but aloes in great numbers, as architectural ornaments, such aloes being cast in lead, and placed in stone, or composition vases, after being daubed over with a vile light-green colour, cockney fashion; and these aloes, too, anything but real imitations of the natural plant. Add to all this, a sharp north-easter, the thermometer

three parts down to zero, and a lot of gardeners sliding on the ice-clad lake, or carrying a cabbage on a long pole, looking over the hall, the castle, or the mansion, decorated in this pseudo style, and you have anything but a picture true to nature or to art.

Although the *Yuccas* have been cut down to the ground by some of our severest winters, they are yet sufficiently hardy to be allowable, in effigies, as accompaniments to architecture, without outraging our ideas of means to an end; at any rate, they are highly appropriate for planting in corners, angles, or other spare places in regularly laid-out gardens, as any one may now see, looking at the new plantation of *Yuccas* in the American garden of the Horticultural Society of London. There is not such another batch of *Yuccas* in the three kingdoms—that is, so fit for planting as ornaments to a flower-garden.

People far off in the country, who knew the old arrangement of this garden, will recollect a large mass of *Yuccas* which stood, for half an age, not far from the great and celebrated *Glycine*, where a short piece of wall projected from the long conservatory wall on which the *Glycine* is trained. All this is now altered: the cross wall is taken down, and the *Yuccas* are removed; so that the whole of the conservatory wall, from the cloak-room to near the council-room, can be seen at one glance—an immense improvement. Some of the *Yuccas* look as old as if they were the very plant from which Adam took his needle, and some of them had I know not how many heads. But now, in their new bed, they are all single-headed, and look as young and thrifty as Mr. Errington's pines which he struck from his best suckers last March, and much after the same style of growth, without any visible sign of a stem to any of them. Many of them promise to flower next year, and that in a manner as far superior to the usual run of *Yuccas*, as the present state of pine-growing is from what it was when Mr. Errington first went into Cheshire; and it is in this very style that they will soon be seen in our best flower-gardens all over the country. But it is sad news to us who are poor, and are members of this Society, to learn that they will not be able to supply us with a single *Yucca* from our own garden, at least, for the next four years, for this reason, that the whole stock has been divided to the last head and sucker for the new plantation, and that the young plants are in such a vigorous state of health, that one can hardly look for a sucker from any of them before the time specified. We must all trudge to the nurseries; meantime, I shall keep on hammering at the subject until every plant of *Yucca*, in every nursery in the kingdom, is made the most of, like those in the Society's garden; and who will venture to say there is nothing new under the sun when I describe the perfectly new way by which the old *Yuccas* in this collection have been renewed to the age of mere suckers?

The more usual way of increasing this family is from suckers which rise from the roots, and from divisions of the head that are branchy; these are slipped off in the spring, and some of the lower leaves being removed, and a few days allowed for the wounds to dry, the suckers are either planted out in the open ground, in some light soil, where they will root during the summer, or they are potted in a light compost, and then plunged in bottom-heat, where they will root much sooner. But when neither suckers nor side branches are produced, Miller, the only author on whom I can lay my hands, who has recommended the plan, directs the head to be cut off, taking a portion of the old stem with it, potting this, and applying bottom-heat to it, when it will soon root; "and this cutting off the heads will occasion the stems to put out suckers, which they seldom do without until they flower; so that by this method the plants may be obtained in plenty." This is the method which

Mr. Gordon adopted with the tops of all his old plants, after divesting them of all side branches. Suckers and offsets he formed into one lot, and all the tops into another, taking off long pieces of the old, dry stems along with single heads; but, instead of nursery rows, and potting for hotbeds, he removed the whole at once to his new plantation, and planted them in as novel a way as his success is complete. Indeed, I never saw anything answer better; formerly he recommended a hole for them, a foot deep and two feet across, to be filled with a good compost; then to plant a sucker, or a well-established plant in the middle, and to press the soil firmly round the stem; on this occasion, however, he tried a new experiment. After opening the holes, he made a compost of half clay and half cow-dung, and stuck in his plants so that the bottom leaves were just within the surface, and then he rammed the compost round the stems as hard as if he was laying the foundation for a pyramid; and if the plant was at all top-heavy, he put a stone on the top to steady it still firmer. The cow-dung kept the clay from drying too hard for the new roots to work through, while the clay was yet firmer than any loam could be for steadying the plants; and as soon as roots were made, there was a rich feast for them to begin with, and the plants now show that they took advantage of it.

I have often seen young pine-apple plants healthy enough to gladden the heart of any old gardener, but I never saw plants more healthy, or better-looking in their way, than these *Yuccas*.

And now, for THE COTTAGE GARDENER: just look round and see if you have a starving *Yucca* anywhere about the garden, with a crooked stem as hard and dry as a May-pole, and if it has ever flowered, the chances are that it has more than one division in the head; all the better; every division of the head will make a new plant. You must now trace where the head divides, and strip off the leaves below that point; then it will be easy enough to slip off every division but the one which seems the most central, this must be left to go with eighteen inches or more of the hard crooked stem to form your premier plant. Never think, for a moment, of taking up the roots, and of transplanting the whole as it is, for that would spoil the whole experiment; you cannot force blood through dry bones, or sap from the old roots up through a stem as dry as a cork; but get young fleshy roots from the very bottom of the leaves, and as far down the piece of stem as they like to come, the sap will flow vigorously, and the leaves will soon be as green as leeks, and as stiff as pokers; and if you plant them as above, and arrange them so as to be in pairs, no matter how far apart, there are no plants that will more stamp the character of a terrace garden, the front of a box terrace, or, indeed, any geometric figure.

At the end of next March will be the best time for all this; *Yucca gloriosa superba* the best plant to use—the one with the purple back to the white flowers, and *Yucca draconis*, or *recurva*, or *recurvifolia*, or *acuminata*, for it goes under all these names, is the next best. This kind turns back the leaves in the middle, looking as formidable as a dragon, which gives meaning to the second name; but *recurva* means that kind of turning in the leaves. The third best kind is *filamentosa*, and it has no stem, but it flowers very freely, and is easily known by the white threads or filaments which hang from the edges of the leaves. There are many more kinds, they say as many as thirty, but these are enough to begin with in a small way. If I had a long walk with grass on both sides, I would make an avenue of these *Yuccas*, planting them ten or twelve feet apart, and six feet from the walk; a more ambitious man, with a large stock of plants in the reserve garden, would try to have every other plant in bloom along both sides at once, and the other half the year following. D. BEATON.

THE GREENHOUSE.

I SHALL shortly advert to several plants, to meet the inquiries of several subscribers.

CANTUA DEPENDENS.

"I have a plant twelve months old; should I let it get quite dry in winter, or how manage it?" This plant may be treated, in many respects, as a fuchsia, but it will not stand so much *dryness* in winter, because its stems are much more slender, and less succulent. Even fuchsias, though rejoicing in a rest in winter, are frequently injured by being kept too dry at that period, especially when it is intended to preserve any part of the old stem. One of the finest plants I have seen of the *Cantua*, was, in my opinion, injured in a similar manner. It had been grown freely during summer in an intermediate house, and was beautifully branched all round from a central stem. It was then put in an airy place, in autumn, to ripen the shoots, and kept cool and dry in winter; but in spring and summer it only showed a few flowers from the strongest and terminal shoot. I think one of two courses should have been followed:—to have kept the plant slowly growing without a check, and waited for the sunny-days of spring and an airy position to get masses of bloom from the end of the shoots; or, what I should prefer, with a strong established plant, allow the wood to get ripened before autumn, give the plant a temperature of about 45° in winter, with no more water than would keep it just moving; then prune it back considerably in spring, place it in a warmer place, or the closest and warmest end of the same house; re-pot, if necessary, when the young shoots are one inch in length; shade, syringe, and encourage with suitable moisture, and, if possible, additional heat, and an open airy position, and the stiff, but luxuriant shoots will furnish you with its beautiful dependant fuchsia-like flowers. The plant will thus require similar management, but a little *more* care than a fuchsia.

Propagation.—The small side-shoots, formed after pruning back, when a little firm at their base, and from two inches in length, make the best cuttings. Take them off, if possible, close to the old stem, wounding it as little as may be; use a lancet-like knife for cutting clean across at the base; remove a few of the lower and small leaves, and then insert the cuttings in silver-sand, over sandy-peat, in a well-drained pot, cover (after watering) with a bell-glass and place any where where shade can be given, and a temperature secured a little higher than the parent-plant previously enjoyed.

Potting.—On getting a small tiny plant, you may continue giving successional pottings as the pot gets filled with roots; but after twelve or eighteen months growth, when the plant is pretty well established, one potting, as instanced above when growth was progressing, would, in every respect, be preferable.

Compost.—Sandy peat, a little turfy loam, and broken pots, for the first potting, increasing the loam in subsequent pottings. When the plant gets established, let the loam be nearly one-half, with a portion of charcoal, broken pots, and dried nodules of cow-dug.

Watering.—Give liberally when the plant is growing freely; lessen as autumn approaches; just see that the soil is not dry in winter; apply weak liquid-manure when the first flower-buds peep, and let the water be aerated, and always as warm, rather warmer, than the temperature in which the plant is growing.

Temperature.—40° to 45° in winter, 50° to 55° in spring, 60° in summer, 50° to 55° in autumn, with from 10° to 15° rise for sunshine, during which, in spring especially, the syringe may be used.

Insects.—Keep free, is the grand thing; fumigate for fly, use sulphur for the spider, but *carefully*, as the plant is very sensitive to brimstone.

DEUTZIA GRACILIS.

It is complained that "this will not grow." It is, however, one of the prettiest things lately introduced; but I suspect it always will be a plant of *slow*, as well as slender growth. A correspondent may expect his plant, four inches high, to produce its pretty white flowers next March, or the beginning of April, if he keeps it all the winter in a common greenhouse. After satisfying himself with seeing the first flower, I would recommend every flower-bud to be removed, and the points of the shoots to be stopped, and the plant placed in an airy, warm corner, to encourage growth. Not that the plant *absolutely* requires heat, for I believe, ultimately it will be found that it is as hardy, or nearly so, as *D. scabra*; while that, again, in many places, has proved itself as hardy as the Philadelphus, or Mock Orange. So long as *D. gracilis* is rather scarce, and in a small state, it would be folly to place it in a shrubbery, or even at the foot of a wall, though, no doubt, ere long, it will be placed in both positions. At present, and especially when in a small state, a dry, cold frame, or pit, or a common greenhouse, will be the most suitable winter quarters. It produces its flowers one season on the slender, well-ripened shoots produced in the preceding; this must be kept in mind when growing and pruning. It grows so slowly, that little pruning, farther than nipping the points of shoots and thinning the young ones, will be required. If these young shoots are well ripened in autumn, extra heat will bring the flowers out any time in winter, especially after Christmas.

Compost.—Equal parts of sandy peat and loam, when young, increasing the loam, and adding leaf-mould and cow-dung as the plant gets older and larger.

Watering.—Give liberally when growing and flowering; lessen the quantity in autumn, and just see that the soil is moistish in winter. In bright days, at the latter period, it will be better to lessen evaporation, by a dusting over the top with the syringe, in preference to soaking the roots. On this account, many small plants, in little pots, that require *rest* in winter, are best kept when plunged *in*, and the pots surfaced with moss. The roots are thus kept easily in an equal state, neither wet nor dry.

Propagation.—Cuttings of ripened one-year-old wood, taken off in autumn, and inserted in sandy soil, under a bell-glass or hand-light, in a cold-pit, the glass, however, not being pressed close down; or small side-shoots in spring, when 1½ inch long, inserted under a bell-glass, and placed in a temperature a few degrees higher than that of the plant from which the cuttings were taken.

DEUTZIA SCABRA.

This, though an old plant, is still a most interesting one, whether used for the greenhouse or the open shrubbery. It is easily propagated by young, stiff, side-shoots, under a hand-light, in a shady place, in June; but easier still, by inserting ripened young shoots in a shady, sandy border in autumn, just as you would do a currant cutting. If grown in pots, and taken into the greenhouse, it will bloom in the end of March and in April. If wanted earlier, it will stand a gentle forcing. Few things are more lovely than its shoots, from two to four feet in length, covered with its beautiful snow-white flowers. When done flowering, and the young shoots are growing freely from the bottom, all the old shoots should be cut away, and the young ones thinned to the required number; five or seven being a good number for a large pot. When growing, the plant will relish manure waterings. Ripening the young shoots is the great thing to ensure fine flowering. Treat it in every respect as you would a favourite raspberry-bush. A good loamy soil suits it.

WEIGELA ROSEA.

This, when treated as a greenhouse plant, may be managed almost in every respect as the above. It seems quite as hardy as any shrubby Philadelphus, or Honey Suckle. I never succeeded so well with it as with the *Deutzia*, though certainly it is worth a little attention for decorating a house in the spring months. It blooms chiefly, not on last year's shoots, but on those of the current season, coming from well-ripened buds on last season's growth. In pruning for blooming, therefore, we must take the *vine*, and the *rose*, and not the raspberry, as our example. The bush character is thus easily produced. Both the *Weigela* and the *Deutzia* may now be lifted carefully, and potted, and if the pot is plunged in any material containing a little heat, while the top of the plant is exposed, the rooting process will be encouraged, and the plants may afterwards be set in the greenhouse, or forced in spring.

ESCALLONIA MACRANTHA.

This, "with a stout stem, eighteen inches high, and nice side branches, four inches long," may be expected to yield you a few of its pretty flowers next season. If, however, a fine specimen is your object, I would not be too anxious for many flowers. Keep it in a moderate greenhouse during winter, and place it in an airy cold pit out-of-doors in summer. Use rather more peat than loam at first, increasing the loam by degrees. The plant, when two or three feet in height, if a young stock has been secured, might be ventured against a conservative wall. Stubby young shoots will strike under a hand-light in summer. Younger ones will strike more quickly at an earlier period; but they must be inserted in sand, over sandy-peat, covered with a bell-glass, and kept in a frame or pit.

CEANOTHUS RIGIDUS.

This, "nine inches high," can hardly be expected to bloom next season, nor would it be desirable, though the species or variety will bloom when in a small state. This and *dentatus*, from their stiff habits, are amongst the best of the semideciduous kinds for greenhouse decoration. Like others, they chiefly bloom on young shoots of the current season's growth, proceeding from well ripened buds of the former year. The plant should, therefore, be kept moving, and no more, during the winter. The young shoots should be cut back to the lowest bud in spring, or nearly so, and this will throw more strength into the young shoots. A warm corner in the greenhouse will be the best place for them until May, then, a cold pit in summer, and full exposure in autumn, defending the plants at the close from heavy rains and incipient frosts. Cut off the greenest part of the shoots in winter; keep the plants cool then, and neither wet nor dry. The increase of heat and sun-light in spring, and the necessary increase of moisture, will give an impulse to the vegetative powers, and young shoots will be freely produced; which, if the plant is old enough, and the wood matured last season, will yield you charming blue flowers in summer. These young shoots, taken off close to the stem when from two to three inches in length, make nice cuttings when inserted under a bell-glass, or hand-light, in sandy loam, with sand on the surface. The pots for plants must be well drained, and then loam, with a little sand and peat will grow them well. Though ornamental for a cool greenhouse, a conservative wall, protected with a glass case, would be the best position for this and the greater part of the species that did not require a tropical temperature.

MITRARIA COCCINEA.

This has as pretty a scarlet tube as any Gesnerwort of them all; but, unlike the most of the group, instead of soft succulent stems and large leaves, it is a compact

little shrub, with small neat foliage. The first time I saw it, visions of flower-beds of it flitted before me. These I have not yet seen realised, and, perhaps, the flower droops rather too much for the purpose; but, as a hardy greenhouse plant it will be of great use in spring and early summer. I am not aware that it has yet been tried out of doors. It will grow nicely in rough peat and loam, and, after it is some size, will stand in a cold pit, or out-of-doors in summer. Fibry peat and sandy loam, rough in proportion to the size of the shift given, will grow it well.

Little pruning, farther than nipping the point of a strong shoot, to produce uniformity of growth, will be required. The pots should be well drained, and about a seventh part of the compost should consist of broken pots and clean charcoal. With good drainage, waterings will be required freely in the growing and blooming season, decreasing as the end of autumn approaches, and giving it but seldom in winter; the temperature in the latter period, with air, at all suitable times during the day, may range from 38° to 45°, allowing a rise for sunshine. I have no doubt the plant would do well near a conservative wall, especially if furnished with a glass-case. Stubby, half-ripened shoots will strike quickest under a bell-glass, when having a slight rise of temperature, shade, &c. Older cuttings will require less trouble, but more time.

R. FISH.

CONIFERÆ.

(Continued from page 398.)

CUNNINGHAMIA SINENSIS (Chinese Cunninghamia, or Broad-leaved Chinese Fir).—Named in honour of its discoverer, Mr. James Cunningham, by L. C. Richards, a celebrated French botanist. It was originally named, by Mr. Salisbury, *Belis jaculifolia*, and by Mr. Lambert, author of a Monograph on Pines, *Pinus lanceolata*. It is the only species yet discovered. Very ornamental, but too tender for the northern parts of England. In Devonshire and Cornwall, and even in Gloucestershire, it has as yet withstood the severity of the climate. No doubt, in many parts of Ireland it would thrive well. It is a very ornamental tree, rising to the height of fifty feet in China and Japan. It is as yet very rare.

CYPRUSSUS (Cypress).—This genus contains an assemblage of trees and shrubs highly valued for their beauty, and well adapted to ornament the pleasure-ground, or form beautiful objects in the Pinetum. Their style of growth, generally upright, and densely clothed with branches and foliage of a pleasing dark green, in some instances, and light green in others, renders them exceedingly beautiful objects. Many species were known and highly valued by the ancients. Pliny mentions a Cypress at Rome which fell in the time when Nero was Emperor, and was judged to be as old as Rome itself. Five hundred years ago a Cypress was planted on the grave of the renowned poet Hafiz, and is yet alive, a living monument to the memory of the poet. There is a remarkable Cypress at Lomna, in Italy, which has attained the height of one hundred and twenty feet, and is more than twenty feet in circumference at the base of the stem. The use of the Cypress as a memento of the departed in cemeteries is well known; even to this day it is used for that purpose in various parts of the Old World: the far-famed Funereal Cypress was seen by Lord Macartney in China, in the "Valley of Tombs." All these particulars recommend the plants of this genus to the peculiar notice of the antiquarian, the scholar, and the man of taste, as well as to the owner of pleasure-grounds, the planter, and the nurseryman. Even the name is interesting, being said to be derived from *Cyparissus*, a handsome youth of the Island of Ceos, who was, according to heathen mythology, changed into

a Cypress; though some authors think the name is derived from the Isle of Cyprus, where one species abounds.

C. CORNEYANA (Mr. Corney's Cypress).—China. A very handsome species, of an elegant drooping habit, not much known, but well adapted to ornament either a small or large garden. Very scarce.

C. FASTIGIATA of Decandolle (Common Cypress).—This species is extensively spread over the South of Europe, Greece, Turkey, and Asia Minor. It is the Cypress of the ancients. It is the species so often referred to by Homer, Virgil, Ovid, and Lucretius, in their poems. The wood is remarkable for its durability. For avenues, it rivals the Junipers and the Arbor Vitæ, associating admirably with the balustrades of a terrace-garden. It is useful, also, to break the outline formed by round-headed low trees. It is perfectly hardy, cheap, and plentiful in the nurseries. There are two varieties, one named *Thujaefolia*, from resembling an Arbor Vitæ, and *Variiegata*, from its foliage being variegated.

C. FUNEBRIS (Funereal Cypress).—This species has been already referred to, as having been seen by Lord Macartney, and it was noticed also by Sir G. Staunton; but we are indebted to Mr. Fortune for introducing it to this country. He published an account of it in the Horticultural Society's Journal, where he describes it as "a noble-looking fir-tree, about sixty feet high, having a stem as straight as the Norfolk Island pine, and branches drooping like the weeping willow. The branches grew at first horizontally with the main stem, then described a graceful curve upwards, and drooped again at the points. From these main branches, others long and slender hung down towards the ground, and gave the whole tree a weeping and graceful form. The form of the tree was very symmetrical, and reminded me of some of those large and gorgeous chandeliers which one sees in public halls in Europe. It has a most beautiful and striking effect upon the Chinese landscape." Perhaps the largest stock in Europe of this favourite Chinese tree is in the nursery of Messrs. Standish and Noble, at Bagshot. We saw them on a visit there already alluded to in writing on the *Cryptomeria japonica*; but the largest of them has not as yet assumed the drooping form. Hitherto it has proved perfectly hardy, and is so plentiful, that nice plants, nine inches high, may be had for 2s 6d, or even less, if a quantity is taken.

C. GOWENIANA (Mr. Gowen's Cypress).—Named in compliment to Mr. Robert Gowen, Treasurer to the London Horticultural Society. This is said to be a low shrub or tree, of some ten feet or fifteen feet high in its native country, California; but, from what we have seen of its quick growth, it must in this country eventually attain a much higher altitude. An interesting, upright-growing species, with very bright green foliage.

C. HORIZONTALIS (Spreading Cypress).—A native of the South of Europe, but perfectly hardy in Britain. Described by Du Hamel as a variety of the Upright Cypress, with the branches spreading out at right angles from the stem. It is like the species in every other respect, and forms a handsome tree forty feet high.

C. KNIGHTIANA (Mr. Knight's Cypress).—The origin of this beautiful species is unknown. From the plants that we have seen of it, it appears sufficiently distinct; it is allied to *C. torulosa*, and, like that species, is rather tender in the northern parts of Britain. T. APPLEBY.

(To be continued.)

ROSES ARRANGED ACCORDING TO THEIR COLOUR.

A CORRESPONDENT, who signs himself "A Derbyshire Subscriber," writes for information about selecting

Roses, so as to have only such as are distinct in colour. He says, "The great objection to these flowers is their sameness of colour. I want to get all the really and strikingly distinct shades, from the darkest crimson to pure white, and thence again to bright yellow." Now, we think this idea a good and useful one, and, as our correspondent suggests, one that would be useful to others, as well as himself, that are about to purchase roses. We, therefore, shall draw up a selection of Roses possessing the property of colour in high perfection. Suggestions of this nature from our readers are always useful; they lead the writers for THE COTTAGE GARDENER to enter upon such subjects as our subscribers wish for information upon, and, by that means, diffuse the knowledge required. Correspondents, therefore, wanting information suitable to their particular locality, need not fear writing for it; but they ought always to send full particulars as to locality, soil, and subsoil—whether the soil is high or low, whether well-drained, and any other particular they may think necessary to be known, in order that the answer may contain the fullest instruction in every point.

To return to our subject of selecting Roses, our correspondent wishes to combine roses for the open border and roses for a wall, or trellis, in the selection. This is somewhat difficult, as there are not so many climbing roses of distinct colours as there are in those that are not climbers. The list may appear somewhat long, but our correspondent, or others, may easily shorten it in giving their orders. The varieties are all good, distinct, and will, we believe, come true to the colours indicated.

"TAKING A LOOK ROUND."

THIS homely phrase is often pregnant with important events. A look round, "with the eyes open," frequently points out what ought to be done without delay; at the same time, a scrutinizing glance at the progress, or otherwise, which certain crops are making, recalls to mind what was done to that crop at the proper time; and either proves the justness or the fallacy of the treatment it is undergoing. "A look round," likewise, discloses many things it would be better to get rid of. If a survey takes place after a period of showery weather, weeds will be found in places expected to be clean, almost in number and luxuriance to dispute with the legitimate crop their right to a share of mother earth. "A look round," at this season, will also be accompanied with the inward expressions of "This job must be done"—"These *Carrots* must be taken up"—"These *Tomatoes* must have the sun"—"These *Cabbage-plants* are stifling each other in the beds, and none planted out yet; I will have that done to-morrow"—"These *autumn-bearing Raspberries* shall not dangle on the ground, and get themselves all dirt in that way, I will see and have them staked up." These, and a thousand other duties suggest themselves at every step when a general survey takes place; or, if we place the case on a higher standing, and allow that the skill and strength of the gardening staff has done all the above at the most fitting time, and that, with a shake of the head, the old garden labourer tauntingly invites inspection of everything in detail, still the eye of the critic, strengthened by the inquiries he makes, enables him to see some things that he thinks may be improved another season by adopting another course, which he explains.

It is thereby seen that "a look round" may be turned to account even in the best kept garden establishments. Now the amateur, who has only a few rods of ground, may also derive some interest, if not knowledge, in this systematic survey; we do not ask him to take stock in a mercantile form, but we ask him to reflect what small, insignificant plants those *Brussels sprouts* were when the peas, which over-topped them, were removed in August, and see how they have progressed since; if he has treated them with liquid-manure, he will, doubtless, be giving that enriching food the credit for their advance; but there is another agent as well, remember; August and September treated us to more rain than is usual for these months, hence the growth of this and similar productions. "A look round" will also display, that if *Early Horn Carrots* have not been removed from the earth some little time, they will now be surrounded by a white beard of new rootlets, indicative of a second growth, and certainly inimical to the root's keeping well. "A look round" will also tell him, that in spite of what great writers say about earthing-up *Celery* by wholesale, he must not lose the chance of the first fine day to do his, if it require ever so little; and, subsequently, the duty becomes still more imperative, as the days will not all be fine after this, and the growing season, which is synonymous with the blanching season, is fast drawing to a close; these, and many other necessary jobs, will suggest themselves, leaving the operator the discretionary power which one to do first; this, of course, must be regulated by circumstances, and the urgency of the individual objects. Suiting the work to the weather, is a golden maxim never to be lost sight of in gardening matters. The fine dry days, so plentiful at Midsummer, cannot be repeated now; consequently, the housing of root-crops, earthing of *celery*, and other needful duties, must have the first attention on such occasions, while a dull day will do to prick out *Cabbage Plants*, prepare ground for the principal crop, (the earliest one we suppose to have been planted some time ago). Beds, with some mode of applying a pro-

tecting article, may be prepared for *Cauliflowers*, which will speedily want planting out in their proper quarters, while *Dwarf French Beans* and *Scarlet Runners* must have mats, or something that way, thrown over them on frosty nights, which are likely now to follow bright days, with a north wind. To these duties may be added that universal one of having an eye to order, cleanliness, and good keeping, which in a garden, even at this time of the year, is not without its merits; still, by-and-by, the removal of bulky things, as *scarlet-runners*, *peas*, &c., and the ground dug after the leaves have fallen, will give the whole that more pleasing appearance which it is difficult to obtain while leaves are falling, and other things (though still useful) present a decaying aspect. One of the principal ornaments of a garden at this untoward season are sound *walks*; these, whatever may be the condition of the adjoining ground, ought always to be good, and at this time of the year their utility is more manifest, when access to the turf, &c. is denied by the damp grass to those for whose enjoyments all that is ornamental in a garden was introduced. Next to walks, are the *edgings*; these, if of box, may also be in nice trim at this season; if they were cut, as we advised, in the showery weather of June, they will have grown sufficiently to show a fresh growth, and yet not so much as to become unsightly large or jagged. Many other little things may be seen to in the way of giving a tidy appearance to the whole, and we can point out no better mode of the amateur finding out what wants doing, than just taking "a look round." J. ROBSON.

THE FORSAKEN HERITAGE.

By the Authoress of "*My Flowers*," &c.

My readers may remember that, some months ago, I described the effects of a thunder-storm as having smitten a tree—an old ash-pollard—and spared the cottage which stood almost by its side. That little cottage was the dwelling of a young widow and her four children, who had lost their earthly prop and stay some years ago. I am now going to tell the story of this young widow, for the benefit of others, who may, like her, be left alone on earth, with only the rich inheritance of God's promise.

Mary Anderson's husband had been a bargeman, and had settled in the village in consequence. His wife belonged to another county; she had no friends in her new parish, but they were steady, respectable young people, very quiet, and very clean; and when poor Anderson began to sink into decline many were kind and helpful to them. After his early death the poor young widow remained still in her little bit of a cottage. It looked away from the village over a sweet, sunny scene; it had a very small garden before the door, and a rough shed at the gable end. This, with a small kitchen, and a yet smaller bedroom, was the home of the widow and her orphan family.

Nothing could be cleaner or neater than Mary and her children. She was always so tidily dressed, without a shred of finery, and her shoes and stockings were so particularly clean and well made, that it was impossible not to notice her. She was never down-at-heel, like many of her neighbours, which gives such a wretched, slatternly look; and she was never seen in torn or draggled clothes, or standing gossiping about. Her two boys went to work, the little girls to school, and the mother was always seated in-doors, busy with her needle, alone, until the evening, when her little ones were also quietly at work by her side. The cottage was, indeed, the picture of what a widow's home should be.

There is a heritage for the widow and the fatherless, signed, sealed, and delivered into their hands, when the grave closes upon him who toiled and fed them. "Leave thy fatherless children, I will preserve them alive, and let thy widows trust in me."

Mary Anderson and her children were preserved alive. She had always work and food; friends were raised up, who sent them clothes; and neater, cleaner children could not

be seen in the parish. One of her boys gave her trouble, but, after leaving one or two farmers in disgrace, he at last got a place where his elder brother worked, and grew more steady and well behaved.

Mary was a kind creature among her neighbours. She would often get up in the night to help her poor bed-ridden neighbour, Betty Lamb. She would nurse the sick, and assist in the houses of her richer friends, when she could be spared from her own duties. She was able, also, to talk well on religious subjects. She knew the truth, and she *seemed* also to know the promise; but what we know we do not always feel; and it is one thing to "speak with tongues," and another to experience the power of the Spirit in our hearts.

A rumour at last spread by degrees through the village that Mary Anderson was going to marry again. No one at first believed it, but a man, who was himself a widower with a family, was seen very often digging in her garden, while Mary stood with her work beside him; and it did certainly look rather like a change, people began to think. Mary flatly denied the fact. She declared to her neighbours she had no thoughts whatever of marrying again; and when spoken to by a lady on the subject, she said quietly, but with her eyes cast down, "I don't know anything about it myself, ma'am."

That Mary was uttering falsehoods at last became evident to all. She became the wife of Sam Spicer, quitted her own little cottage, and entered upon her new home and duties, which lay at the other extremity of the parish. Mary had a right to marry again if she chose—there was no human reason why she should not; but it was plain that she condemned herself for doing so, by flatly denying the fact. Oh! nothing *can* prosper that is entered upon with a lie! God will not, He *cannot* bless it; and without His blessing—nay, with the curse upon "all liars" resting upon us—how can we reasonably expect even common good to arise from our undertaking?

Mary Spicer forgot the *promise*, or, at any rate, she gave it up with all its rich abundance, when she cast off her "first faith," and became the wife of a violent, savage-hearted man. No doubt she thought him what he professed to be, as *we* generally do upon these occasions, but her ground for so thinking was sand. He talked well, and deceived her. Let woman *watch the life*, and not listen to the words of the man who seeks her hand; let her be as "the deaf adder" to his voice, and open wide the eyes of her understanding to his actions. Mary Anderson closed her eyes and listened; and upon Mary Spicer's brow was stamped in deep characters, "Ichabod."

When the promise was cast aside, Mary soon felt the difference. She was shut up at a distance with her new partner for life; but the sad truth was soon made known and blazed abroad. Her poor little girls came among their old friends in the village with melancholy tales of all their misery; their backs and arms were black with blows; and they were glad to get out of the house and wander about any where, and any how. The sons were as miserable as the daughters; they idled about, rather than go to such a home; and instead of being clean, and well cared-for in their dress, they could not get their clothes properly washed or mended. Mary is seen now and then stealing through the village, downcast and dispirited. Her neat, cheerful look is gone, and she turns away as fast as she can from the gaze of her former acquaintance. How she must mourn in heart as she passes the grave of her first husband, and the cottage where the promise rested, and gave her so many blessings! How she must weep as she reads the title-deed that God has given to the widow, and that she threw madly away! She had *tried* the deed, and found it "faithful and true," so that her sorrow and self-reproach must, indeed, be almost too great to bear. Her violent husband treats her as cruelly as he treats her children; they share the same fate; but the bitterest pang to the mother's heart must be the stroke that falls upon her helpless and unoffending orphans.

Let the fate of Mary Spicer ring in the ears of all in her circumstances. Let it be a powerful warning to them not to cast off their "first faith," but to hold fast to the promise, and fear not that it will ever fail. While Mary sat quietly in her cottage, with her children round her, all went well

with her; the hand that rules the world, and that guides the bolt of heaven, can cover the heads of those that trust in Him, and shield them from every danger. Has He not said Himself, "Leave thy fatherless children, I will preserve them alive, and let thy widows trust in me?"

In my next paper, I shall sketch the life of one who dwells in the same village with Mary Spicer, and who is "a widow indeed."

BRITISH EATABLE FUNGI.

IN treating on these, I shall first speak of them collectively, and, secondly, confine myself exclusively to those indigenous to our British isles. Fungi are the most nutritious of all vegetables, and the nearest approach to animal food; some, if moderately used, are most nourishing in their raw state, as they lose their good qualities by culinary preparation; and those who have lived entirely upon them in their raw state for some time, with bread and water, state that they have experienced rather an increase of strength than otherwise. When eaten in this state, however, those should be chosen which have a solid flesh, and an agreeable smell and taste, as *Agaricus campestris* (Common Mushroom), *Agaricus procerus* (Tall Agaric), and *Tuber cibarium* (Truffle), &c.

I have little doubt that the very dread of the term Toadstools, and the unsightly appearance that some assume when growing in damp, gloomy, and unhealthy places, to those who do not appreciate their veiled beauties, together with the idea that the venom of serpents and toads renders fungi poisonous, and that, with the exception of the common mushroom, they are all injurious, has caused, through prejudice, which is too prevalent in this land, that valuable and most extensive order of plants to be despised and rejected as an article of food. A gentleman, who has travelled nearly all over the continent, informs me, that fungi appear in most of the markets, and are abundantly eaten, and that he never saw in the public journals, or otherwise heard of a case of poisoning from them. In Russia, Poland, and throughout the greater part of Europe, they form delicacies amongst the rich, and a regular article of diet to the poor people, whole tribes being frequently nearly wholly supported by collecting them; for, in addition to the immense amount of food they supply in their fresh state, they are abundantly preserved by drying, or soaking in oil, vinegar, or brine, and form a valuable article of commerce, from the products of which the poor man is enabled to purchase other necessaries, which he otherwise would be deprived of. To such an extent was the sale of fungi carried on in Italy, that in 1837 it was deemed necessary to fix a definite time and place in the public markets for the sale of fungi exclusively, and to appoint an inspector, who should examine the baskets brought into the city by the peasants previously to their sale. In most uncivilized countries they have been used as an article of diet by the natives, and in Australia, *Militaria Australis* is a fungus known as "native bread."

With respect to the cultivation of esculent fungi, little has been done in Britain, with the exception of the *Agaricus campestris* (Mushroom), which it is well known is cultivated by good gardeners with as much success as other vegetables, and it is extensively cultivated in the ancient quarries which run under part of the city of Paris. The *Agaricus campestris* is native to the whole of Europe, part of Asia, Africa, and America—reaching as far north as Lapland, and as far south as Barbary.

On the continent many others have been tried, with more or less success; and I see but little reason why many should not be cultivated largely in this country, and enable us to enjoy a good supply of delicious food, which is now entirely neglected. *Boletus edulis* is cultivated largely in Paris, simply by watering the ground under oak trees with water in which a quantity of the Boleti have been allowed to ferment, the only precaution necessary being to protect, by fencing, the ground destined for their production, as deer, pigs, and rabbits are very fond of them; this plan is said to be infallible, and much practised in France. In Germany, the *Morels* were so much esteemed, that the peasants who collected them, observing that they grew most abundantly where wood had been burnt, set fire to large forests to

favour their growth; and to such an extent did this injurious practice proceed, that it became necessary to enact severe laws for its suppression. The *Truffle* has been cultivated on the continent with more or less success; a light, dry soil appears most favourable to its growth; but, like other fungi in their natural state, it is a most capricious plant.

It is well known that serious accidents have arisen from the careless way of collecting and preparing fungi for the table (which I shall endeavour to explain in a future paper on the Poisonous Fungi). For collecting, therefore, fine dry weather should be preferred, and those should be chosen cautiously which grow in wet, shady, and unhealthy situations, although they are well known to be wholesome species; those being preferred which are found in open, dry situations, and exposed to light and a free current of air. A flat-bottomed wicker basket, with clean cloth, as used in the south of England in the markets for eggs and butter, should be chosen, also a house-painter's brush should be provided, to remove dust, dirt, leaves, insects, &c., and a knife to remove the roots; the stems may be cut off close, and should generally be rejected, and the fungi may then be closely packed. They should always be gathered before fully grown, and all that are maggoty, or attacked by insects, also all that have been dislodged from their resting-place by boys or cattle, should be rejected. Having obtained as many as required, they should be conveyed home, and, with as little delay as possible, prepared for the table, or preserved for future use.

I find space will not allow me, as I intended here, to enumerate those most esteemed as food in different parts of the globe; I shall, therefore, defer it to my next paper, which will also contain receipts for cooking.—F. Y. Brocas.

(To be continued.)

THE HONEY HARVEST.

I BEG to offer my mite to the common stock. Up to the month of July, I never knew so bad a season since I have had bees. An agreeable change at that time took place, we had copious showers of rain, and then splendid weather to the end of the month; after which the honey gathering season is about over in this locality, as it is principally an hay-growing district.

My No. 1 swarm, an artificial one, was taken off June 19th, and put into one of Taylor's Bar Hives, and placed where the stock formerly stood (according to the "Country Curate's" plan, which answered very well in preventing any casts from coming off). But there is danger of over-doing it, as a neighbour of mine did, as in his case there were not bees enough left to defend the hive, which was attacked by a neighbour's bees, who succeeded in carrying off every particle of honey, in spite of narrowing the entrance to the hive. However, I could not, by any means, induce them to work in the super, although the stock-box was full of honey, nearly down to the floor-board. So I fumigated them, and took two bars of comb out weighing 7 lbs.

No. 2, also an artificial swarm, taken off June 23rd, into a common cottage hive, plundered it the middle of August, and took 18 lbs. of honey from it.

No. 3, natural swarm, June 25th, which was a very small affair, as we did not see it go off, but found it hanging from a tree close by, late in the evening, and I suppose the principal part of the bees had returned back again to the parent stock. I supposed, by placing the swarm in the stock's place, I should get plenty of bees to it. But I was woefully disappointed, for a most deadly warfare commenced. The result was the loss of a greater part of the bees. Can any of your readers account for the fighting?—the swarm must have come out of the hive that I attributed it to, there being no other at all likely. (But I observed fighting, more or less, at all the swarms that had been put where the stock formerly stood.) From this swarm I took 12 lbs. of honey, by destroying the bees.

No. 4, a Nutt's Hive, the bees of which I could not induce to work in the side-boxes. Swarmed July 1st; hived it into one of the side-boxes, thinking it would commence working

there; but no, the next morning I found them all united in the centre-box again. At the end of seven days, that is, July 8th, it swarmed again, and a magnificent swarm it was, and I hived it into a common hive. In the course of a week I placed an eke under it, and at the end of fourteen days it swarmed. From this swarm I took 28 lbs. of honey. The same Nutt's Box threw off a cast, a few days after which I hived it into a straw cup. From this I took 6 lbs. of honey, by fumigating it, and adding the bees to one of my stocks, as I considered they would be principally young bees, and might be of some service. I have abandoned the plan of adding the bees that I plundered to those intended for stocks, as I could see no benefit from it the spring following. I consider they only help to eat up the food of the stock, and then die before they are of any service to the stock, unless bees live to a greater age than is generally supposed.

By-the-by, I saw a notice a short time ago, in THE COTTAGE GARDENER, that the Entomological Society had offered a prize for the best treatise on the longevity of bees. I am anxiously waiting the result. I think it a very good bit of the "Country Curate's," to preserve the brood from the hives you are plundering. I took mine carefully out, and arranged it upon the top of two of my stocks, then placed empty hives over it, and the bees presently came through, and hatched it out, which appeared to strengthen those stocks very much.—H. T. N.

P. S.—I have just seen a drone bee go into my No. 1 stock (Sept. 25th). I saw a great many the beginning of this month. Do you think they are without a queen? if so, what will be my best plan with them?

NEW MODE OF MANAGING BEES.

I HAVE much pleasure in complying with your request, and forward you the following particulars relative to the method adopted by me at your suggestion, in the case of the only four swarms which came off in my apiary. As soon as the swarms had left the hives, the stocks were stopped up; the swarms, as soon as hived, put in the place of the stocks, and the stocks removed a short distance, and kept closed from 24 to 36 hours.

No. 3 sent out, 19th June, a swarm weighing 5½ lbs. On unstopping it, the workers began to eject the drones with frightful rapidity, no other kind of work was carried on, and the hive, for we could see into it on the back side of the box, appeared clear of them in a few days. On the 14th day from swarming, a few were seen; on the 20th, piping was heard; and the following day a young queen was cast out. On the 26th July, some of the old combs were removed, from which 4¼ lbs. honey were run; 1½ lbs. of bees was added to this stock on the 26th August, and 3 lbs. sugar, and 1½ lbs. honey, prepared as directed in Golding's Is. Bee book, was supplied previously to the 1st September, when it weighed 9¼ lbs. From the swarm No. 19, ten pounds of honey were run on the 19th August.

No. 13 sent out, 19th June, a swarm weighing 4¼ lbs. Immediately on its being unstopped, drone ejection commenced, and in a few days the work appeared to be completed. On the 30th July, some combs were removed, from which 3 lbs. of honey were run. No drones were then seen. As this stock did not appear to progress well, it was taken up on the 4th August, but contained no honey, no brood, no queen, and only half a pound of bees. The swarm, No. 15, was deprived, 29th July, of 7 lbs. of honey. No. 6 sent out, 1st July, a swarm weighing 4½ lbs. The pan on top was removed, and as it contained comb with drone and worker brood, and royal cell with princess, it has, with the addition of 2½ lbs. of bees and feeding, made a little stock. As soon as the parent-hive was unstopped, the workers threw out, in the course of two or three hours, between six and seven ounces of drones. No honey has been taken from this hive, 1¼ lbs. bees was added 24th August, and it weighed, 1st September, 12¼ lbs., or a little more than one-half of what it weighed 1st September, 1851. The swarm, No. 4, was taken up 24th August, and yielded 7 lbs. honey.

No 2 sent out, 3d July, a swarm weighing 4¼ lbs. Drone ejection was proceeded with, as in the three cases above-named, with great rapidity. Removed side-combs, 30th

July, and ran 2½ lbs. of honey. No brood was observed. On the 5th August, added ¾ lb. bees; 26th August, 1½ lbs. bees. Prepared food, 5 lbs. sugar, 1½ lbs. honey, was given previous to 1st September, when it weighed 7 lbs. From the swarm No. 16, when taken up 24th August, 7¼ lbs. of honey were run.

No cast has issued from either of these hives. My assistant and myself, in thinking over the case of No. 13 within the last few days, have considerable doubts as to the existence of any royal cell in it. On taking up No. 7, that had not swarmed, none was found. I must leave you to judge of the merits or demerits of the new mode. On these particulars you may rely. It is my intention to try it again next year, but I would not recommend it to be adopted with all the stocks in an apiary, since, from the wholesale and sudden expulsion of the drones, and the uncertain nature of our climate, the requirements of the queen might not be met in time. Huber, if I remember rightly, states that this should be within thirty days.

I send you herewith an account of what twelve stocks and four swarms have done with me, North Bucks, and having had under my notice from fifty to sixty other hives that have been taken up, a very large portion of which I fumi-

gated myself, I am of opinion that my own apiary presents a more favourable report than I should have been able to give, could I have ascertained in all cases the weight of honey run from each hive. In many cases of stocks and swarms, of which I have heard, it has varied from four to six pounds. I fear there are very few stocks or swarms in this locality that can stand the winter without feeding. I shall hope that we may be favoured next year with a season as productive as that of which C. R. R. writes. Query. Does he weigh his hives, swarms, honey, &c.? As accuracy is so essential to the formation of correct opinions, I would suggest to him and your other correspondents, to avoid in future the terms "very large," "enormous," "amazing quantity;" the ideas they convey are so vague. A bee-keeper of forty years standing sent me, as he said, an "enormous" quantity of bees, and laid a wager, for which I reproved him, with the person who brought them, that they weighed 5lbs. I weighed them accurately, and they were found to be only 2¼ lbs.

P. S. I should feel much obliged to C. R. R. if he would give me the size of his "very large" hive, the weight of his "enormous" swarms, as well as that of his "amazing quantity" of honey of other sorts than top honey.

Particulars of Twelve Stocks and four Swarms.—Season, 1852.

Description and kind of Hive used.	Wt. 23rd April, 1852.		Wt. 23rd June, 1852.		Year of the queen's birth.	Honey taken from top in glasses or pans.	Honey taken by the removal of combs.	Honey run from combs on taking up hive.	Bees added Aug., 1852.	Prepared food supplied in August, 1852.		Wt. 1st Sept., 1851.			Remarks.
	Sug.	Hon.	Wt. 1st Sept., 1851.	Wt. 1st Sept., 1851.						Wt. 1st Nov., 1851.					
STOCKS.															
1. In Neighbour's cottage hive - -	9	..	1851	g. 7½	1½	23½	27½	24	24	24	Swarmed and cast, 1851; cast returned; 7¼ lbs. comb in glass taken, 1851.
2. In straw-hive, wood top, 12 by 8½ in. -	4½	12½	1850	..	2½	..	2½	5	1½	7	..	14½	14½	14½	Two swarms 19th June, 1851; 14½ lbs. comb taken in small hives in 1851.
3. In Taylor's bar-hive, 11½ in. sq. by 8½ in.	6	5½	1851	..	4½	..	1½	3	1½	9½	16½	15½	15½	15½	Sent out a swarm of 7 lbs. 21st June, 1851; 3½ lbs. honey taken from side combs in 1851.
5. In straw-bar hive, wood top, 15 by 10 in.	8½	15½	supd. 50	1½	25	18½	24	24	24	Formed from 7 lbs. bees put into empty hive at various times, between 11th and 18th Aug., 1851.
6. In common straw-hive, 12 in. by 8½ in.	11½	16½	1851	1½	12½	25	23½	23½	23½	Swarmed and cast, 1851; 1½ lbs. comb in glass, taken in 1851.
7. In do. do. do. -	7½	..	supd. 50	g. 2 p. 6½	12	19	19	19	Formed from 7 lbs. bees put into an empty hive at various times, between 26th August and 8th Sept. 1851.
8. In straw-hive, wood top, 14 in. by 7 in.	4½	..	1850	..	3	12½	..	14½	14½	14½	Swarm of 1st of June, 1851; deprived of 13½ lbs. honey, and fed freely for winter of 1851; cast of 2 lbs. added 17th June, 1852.
9. In box diag. bars, 11½ in. by 6½ in. -	6	..	1851	g. 6	3	25½	18½	17½	17½	17½	Two casts of 1851; no honey taken in 1851.
10. In straw-hive, wood top, 12 in. by 8½ in.	3½	10½	unkwn.	9½	13	13	13	Stray swarm of 1851 purchased 19th June; no honey taken in 1851.
11. In do. do. do. -	7½	11	1851	g. 1	14½	22½	20½	20½	20½	Swarm of 21st June, 1851, weighing on that day 6½ lbs.; no honey taken in 1851.
12. In common straw-hive, 12 in. by 8½ in.	9½	10	supd. 50	6½	16	16	16	Did not swarm, 1851; no honey taken in 1851.
13. In do. do. do. -	5½	4½	1851	..	3	Nil	15½	15½	15½	Cast of 2 lbs. 23rd June, 1851; no honey taken in 1851.
SWARMS.															
14. In Taylor's bar-hive, 11½ in. by 8½ in.	1851	10	This hive increased from 3rd to 10th July, 8½ lbs.
15. In common straw-hive, 15 in. by 7 in.	1851	..	7	12	4	15½	This hive increased from 3rd to 10th July, 9½ lbs.
16. In do. do. do. -	7½	This hive increased from 3rd to 10th July, 6½ lbs.
4. In straw-bar hive, 12 in. by 8½ in. -	7	This hive increased from 1st to 10th July, 9½ lbs.
..	22	23	52½	7½	20	6½	145½	

I cannot speak with certainty respecting all these hives, but, judging from the eight which I weighed several times, I am of opinion that they have, on the average, decreased since the 18th July. Looking at the above statement, it is evident that had no honey been taken from these 16 hives

they would, after consuming 20 lbs. sugar, and 6½ lbs. honey, and receiving 7½ lbs. bees, have only weighed on the 1st September, 1852, 243 lbs., or 77 lbs. less than they should have done to stand the winter. Your readers must form their own judgment from these facts.

B. B.

THE LIVERPOOL POULTRY SHOW.

THE fifth annual show of the Manchester and Liverpool Agricultural Society was held on the 23rd of September, in the capacious Market Place, in Great Homer-street, Liverpool. For the first time, the Society added a show of poultry to the other attractions of its Exhibition, and we congratulate them on the success of their first experiment in this interesting department of rural economy. This, as our readers are aware, is not a good time of the year for showing to advantage their feathered favourites, but, making reasonable allowance for this drawback, this new feature of the Society's exhibition was highly creditable. As is our usual practice on such occasions, we proceed briefly to notice each class. The *Dorkings*, which were the first class here, presented some good pens of fowls, the prize being awarded to Capt. W. Hornby, for three very good birds. The same gentleman carried off the prize in the *Spanish* class, in which there was nothing approaching in excellence the birds exhibited by him; and he was equally successful in the *Game* class, against two or three very good competing pens. In the *Cochin* class, the prize was very deservedly given to Dr. Gwynne, of Sandbach, for three very fine fowls; this class altogether was not first-rate. Of *Malays*, there were none shown, and the *Hamburgh* and *Poland* classes were not good enough to deserve notice. The *Geese* came next, and Mr. Townley Parker again carried off the prize, as he did also in the class of *Goslings*—Capt. Hornby running him very close in both classes. Capt. Hornby obtained the prize for *Aylesbury Ducks*—those for *Rouens*, and for "any other variety," being awarded to very good pens belonging to Mr. Henry Worrall. One pen of *Turkeys* only was shown, by Mr. E. W. Wilmot, but they were excellent, being of the "wild American breed." In the *Duckling* class, the prize again fell to Capt. Hornby, for six beautiful *Aylesburies*; Mr. Townley Parker's *Rouens* being but little inferior to them. In the class of "six chickens," some very fine birds of several varieties were shown, and the judges gave four prizes. Three of them were awarded to Capt. Hornby, for *Cochins*, *Dorkings*, and *Spanish*, respectively, and the fourth to William Copple, for *Bolton Greys*. The Society's medal for the best pen of birds in the yard, was adjudged to Capt. Hornby, for his six *Cochin* chickens, making the tenth prize obtained by him; a proof of what may be accomplished by the judgment and attention of an individual fancier.

With the exceptions to which we have referred, there were some good birds shown in each class, and we have no doubt that the success of this, their first attempt, and the interest excited by this portion of their exhibition, will induce this spirited Association to repeat the show of poultry in succeeding years; and that as the interest taken in them increases, and the encouragement given by the different Societies is extended, the different breeds of domestic fowl will be improved, and disseminated throughout the country.

The judges were Mr. Bissell, of Birmingham, and Mr. Nolan, of Dublin, and their decisions appeared to give universal satisfaction. The arrangements of the show by the secretary, Mr. White, were very judicious, and the poultry pens were as good as we have seen anywhere.

LIST OF PRIZES.

- One male and two female birds to be shown by each competitor.
- For the best white, speckled, or grey *Dorking Fowls*, £1. Captain W. W. Hornby, Knowsley, near Prescott, pen of fowls, of the *Dorking* breed, aged about 2 years.
- For the best *Spanish Fowls*, £1. Captain W. W. Hornby, Knowsley, near Prescott, pen of fowls, of the *Spanish* breed, aged about 2 years.
- For the best *Game Fowl*, £1. Captain W. W. Hornby, Knowsley, near Prescott, pen of fowls, of the *game* breed, bred by himself, aged 2 years.
- For the best *Cochin-China Fowls*, £1. William Cust Gwynne, M.D., Sandbach, Cheshire, three fowls, of the *Cochin-China* breed, bred by himself, and hatched, the cock at the end of March, and the pullets at the middle of March. On sale. Price £20.
- For the best *Malay Fowls*, £1. No entries.
- For the best *Golden-pencilled Hamburgh Fowls*, £1. The variety called "Bolton Bays" or "Golden Hamburgh" fowl, must be exhibited for this premium. No entries.
- For the best *Silver-pencilled Hamburgh Fowls*, £1. "Bolton Greys," "Chitterprats," and "Silver-pencilled Dutch," to be shown for this premium. John Taylor, Halshaw Moor, near Bolton, pen of fowls of the *Silver-pencilled Hamburgh* breed, bred by William Hill, aged 4½ months.
- For the best *Gold-spangled Hamburgh Fowls*, £1. "Golden Pheasant,"

"Golden Mooneys," "Copper Moss," and "Red Caps," to be shown for this premium. R. C. Lowndes, Club-moor, near Liverpool, pen of fowls, of the *Golden-pheasant* breed, bred by himself.

For the best *Silver-spangled Hamburgh Fowls*, £1. "Silver Pheasant," "Silver Mooney," and "Silver Moss," fowl, to be shown for this premium. No award.

For the best *Poland Fowls*, £1. Black, with white crests, golden or silver. No award.

For the best of any other breed or cross of *Fowls*, £1. The breed to be stated on entry. Captain W. W. Hornby, Knowsley, near Prescott, pen of fowls of the *Gold-laced Bantam* breed, bred by himself, aged 1 year and 3 months.

GEESE.

For the best *Geese*, £1. Thomas Townley Parker, Sutton-grange, near St. Helens, geese of the common breed, aged 3 years.

DUCKS.

For the best *Aylesbury Ducks*, £1. Captain W. W. Hornby, Knowsley, near Prescott, pen of ducks, of the *Aylesbury* breed, bred by himself, aged 1 year and 4 months.

For the best *Rouen Ducks*, £1. Henry Worrall, Knotty-ash House, Liverpool, pen of ducks, of the *Rouen* breed, bred by — Henderson, Esq., aged 8 months.

For the best of any other variety of *Ducks*, £1. Henry Worrall, Knotty-ash House, Liverpool, pen of ducks, of the crossed wild breed, bred by himself, aged 1 year and 1 month.

TURKEYS.

For the best *Turkeys*, £1. Edward Woollet Wilmot, Hulme Walfield, near Congleton, pen of turkeys of the wild American breed, hatched April, 1851.

YOUNG POULTRY.

The day on which they were hatched to be stated.

For the best *Six Goslings*, £1. Thomas Townley Parker, Sutton-grange, near St. Helens, goslings of the common breed, bred by himself, hatched on the 10th April last.

For the best *Six Ducklings*, £1. Captain W. W. Hornby, Knowsley, near Prescott, pen of ducklings, of the *Aylesbury* breed, bred by himself, aged 4 months.

For the best *Six Chickens*, £1. Captain W. W. Hornby, Knowsley, near Prescott, pen of chickens, of the *Cochin-China* breed, bred by himself, aged 5 months and 5 days.

Captain W. W. Hornby, Knowsley, near Prescott, pen of chickens, of the *Dorking* breed, bred by himself, aged 4 months.

Captain W. W. Hornby, Knowsley, near Prescott, pen of chickens, of the *Spanish* breed, bred by himself, aged 5 months and 1 week.

EXTRA PRIZE.

For the best pen of Poultry in the show yard, the Society's SILVER MEDAL. The judges awarded it to Captain W. W. Hornby, for *Cochin-China* chickens.

NOTES UPON BACK NUMBERS.

THE *Palma Christi* is not difficult to grow as an out-of-doors plant. It should be raised in the spring hotbed, shifted once liberally, and treated exactly as a balsam till the frosts are over, when it should be planted out in very rich soil, or what would be still better, plant it like a vegetable marrow, with a barrowful of hot manure beneath the soil. Many other tropical plants would grow and show their fine foliage in the summer time if treated thus, and there is not a handsomer one than the *Palma Christi*. All laterals and blossoms should be carefully removed till the plant is four or five feet high.

The *Hybrid Begonia parviflora* by *Cinnabarina*, is now in flower in my stove. It is a miniature *Cinnabarina* in habit, more branched and flowery, but inferior in colour. The pollen of *Cinnabarina* colours some of its mules highly, but others not so well.

Funkia subcordata will not flower satisfactorily out-of-doors, and generally not even in the greenhouse, the flowers being usually deformed by the curling or unequal expansion of one side of the flower. In the stove there is not a more exquisite plant. The flower is of the whitest white I know, the scent delightful, and the leaf a form for the sculptor. Small plants do the best, grown from pieces broken off from the mass in the spring, and each containing one, or at most two crowns.

Your correspondent's "black *Geranium*" was probably *Hoarea melanantha*, a weed, in fact, as he says, but some pretty mules were raised from its pollen some years ago. He must not be cross about his first turn at African bulbs. They, and all imported bulbs, are hard to establish, even for an old hand, sometimes. These little Africans are highly interesting plants, and the time will come, and that soon, when everybody will be running after them again.

Our good instructor, Mr. Beaton, alludes to a tropical experiment of mine. It was not, however, an old hotbed, but a new one made for the purpose, only very spacious and

shallow; one foot was the depth of hot dung, but this was trodden very firmly down on the brick bottom, and enclosed by a little brick-wall to that height. I wished to try if a large and shallow mass would produce and retain the heat as well as the same quantity in the usual more cubical shape, and I think it did so. Most of the tropical plants likely to be experimented upon, such as the South American *Scitamineæ*, and the like, would, if our climate continued as it is to day, be in their beauty, as to blossom and good development, about Christmas day. We, therefore, try to give them such a start, by means of the bottom-heat, as will enable them to begin soon enough to be ready to flower and thrive while our fine weather lasts; but this, the perfection of the thing, will not be done till we try Mr. Beaton's plan of a cheap and simple means of bottom-heat, always at command; while above ground, the plant enjoys what it never gets in our plant-houses, fresh air and exercise. Many men have many minds, and so have the many members of the large family *Amaryllis*. Scarcely any two require exactly the same treatment. The name of the sorts should be given to prevent poor Editors giving evasive answers. Much of this difficulty will cease when warmed borders in the open — In two minutes I shall be on my hobby, so adieu.—A CORRESPONDENT.

(From whom we hope to hear very often.—Ed. C. G.)

MR. RIVERS'S CRYSTAL PALACES.

To gardeners and amateurs. You are all well aware of the annual trouble and expense of fruit-trees on walls, after pruning, nailing, and covering (*but not protecting*), for that is almost an impossibility in our northern parts, and frequently is an entire failure in the more southern districts. Gardeners have been for years crying out—"I'm afraid I shall not be troubled with much fruit this season, as my peaches, pears, plums, and cherries, all apparently are cut off by the frost, and it's nothing but an entire disappointment." Now, to prevent all this, I would earnestly recommend all horticulturists and lovers of gardening to step into Mr. Rivers's nursery, and see there fruit grown to the greatest perfection, such as peaches, plums, pears, apricots, and apples. I, myself, was highly gratified, two months ago, by a visit to his nursery, likewise, at the same period, to the seat of Lord Roden, where I saw, in both places, peaches and apricots in pots, laden with admirable fruit. What would be more pleasing and interesting than to have one or more of these pots, with the sides washed, and the surface covered with a carpet of moss, placed on a nobleman's table, with three to four dozen of beautiful fruit on each plant, which is very easily to be had with only a slight attention. There is no nailing, no tying, and no covering at night with these, only a little additional watering and pruning, as our kind friend Mr. R. directs. And I am sure that the ladies would take great pleasure in gathering the fruit themselves in their dining-rooms. Some are apt to say that the "orchard-houses" are nothing more than rickety cow-sheds, but for them to be convinced about that, I should strongly recommend them to pay one of these structures a visit. Perhaps some of our aged friends, in the same capacity of gardening as myself, would like to know how Mr. R. manages to produce his fruit so abundantly, and if they inquire of him, I have no doubt he will inform them, as I know he is always pleased to give any one information concerning their well-doing. I can safely say, that I could grow fruit in the same way very satisfactorily, although not of so much experience as some; but I hope, as glass is so cheap, that I shall be able to see, one day or other, an orchard-house as large as the Crystal Palace that stood in Hyde Park.

A. B. C.

POULTRY MANIA.

DORKING, *versus* COCHIN-CHINA.

"*Tantas componere lites.*"

(To decide so great a controversy.)

Virgil's Eclogues.

COCK-FIGHTING, as a national pastime, has become defunct, and in lieu thereof, the owners of cocks have entered into strife among themselves; happily, however, the fight

is a bloodless one, and *in the main* is limited to ink-shedding. Most learned have been the controversies, most conflicting have been the facts; and but one truth stands conspicuously forth, namely, that a fowl which passes under the name of "Cochin-China," is just now "the pet of the fancy." We hate foul play, and, therefore, candidly confess, that *why* this has come to pass we cannot determine. Vulgar people insinuate, that it arises from a vain desire to imitate Majesty in small things; and just as the daughters of the honest burgesses of this realm, on all occasions, threw back their veils in a coil around the sides of their bonnets, and tied them in a knot under their chin, on hearing that the Queen, *in a stormy day*, was seen with the bonnet thus accoutred, so have "Cochins" become the fashion, because a few "noble specimens" of the breed occupied a conspicuous position in Her Majesty's aviary. We reverence royalty, wherever we find it. When a king squints, it becomes his subjects to squint likewise. We have heard of a courtier who said he would bow to a thistle, if it were surmounted by the crown of his sovereign. We honour the sentiment. Where is the hungry donkey that would not perform a like act of homage?

But to return to the Cochin-China fowl; what are its qualities? In what special excellence does it transcend the whole race of Spanish, Dorkings, Polands, or Game? In size—in that estimable quality in which a painted sign-post surpasses one of Mulready's cabinet pictures—in that important endowment in which Daniel Lambert was superior to Lord John Russell, and in which the elephant surpasses a man. All its qualities are colossal; and, therefore, in an age when people wish "to get *as much* as they can for their money," they are popular, fashionable, and "the pet of the fancy." It is true, that when they are young, they are superlatively ugly; when at adult age, superlatively tough; and when old, these two qualities are blended in a superlative degree. But *then*, they are very large, very dear, and very fashionable; and these qualities, with the majority, are sufficient to compensate all other defects. The poultry-shows, generally, proclaim that these tailless birds are, as we have described them, "pets." They have all the "prestige" of novelty. All the fervour and enthusiasm which Englishmen lavish on foreign favourites, whether Italian singers, French ballet-girls, Swiss valets; or German nurse-maids, are now bestowed on these emigrants from India, Cochin-China, and the Malay peninsula. Their names appear daily in large capitals in the advertising sheets of the *Times*, the *Gardener's Chronicle*, and other first-rate journals. Mr. Stevens, the auctioneer for all the property connected with natural history in its wide-spread ramifications, exhausts his oratorical powers in their praise; and every dandy who hears of poultry-shows exclaims—"Aw, I've no taste for these things, except, aw, except for Cochins; the rest are low, sir, decidedly low." And yet, in spite of all this dilettanti dandyism—this popular favour—we venture to predicate, that the Cochin-China fowl will disappear as such;—like the Arab horse in England, it will become lost in crosses with other breeds, and be represented by a race possessing their great size, without any of the numerous defects which now characterize the bird.

During the past summer, we saw a Cochin chicken running about at three months old, with "dowl" upon his back, with legs nearly as long as a Flamingo's, and as bare behind as a picked goose. He had, it is true, "roughed it" bitterly, and, therefore, did not resemble very closely the pets of Sturgeon and Punchard—yet he was a genuine Cochin; and around him, reared under, and exposed to precisely the same influences (birds of the same nest and hatch), were gaily congregated chitteprats, half-bred game chicks, and a host of mongrels, carrying in their veins as heterogeneous a mixture of vital fluid as rolls in the arteries of a Yankee, and yet these were all well-feathered, respectable, and decorous, waving their tails with modest dignity, while the unfortunate Cochin ran about as bare, if not as ornamental, as that variegated baboon, who rejoices in the euphonious name of "Cynocephalus maimon." It would become the exertions of benevolent young ladies to make flannel coverings for these ornithological nudities, if such a breed is to be encouraged to the exclusion of the more useful and ornamental denizens of the poultry-yard.

A short time ago, some Cochin-China fanatic was awfully angry with the Royal Agricultural Society for placing the "Dorking Fowl" in Class A of their prize list, instead of the Cochins; but what *could* a farmer do with a lot of naked Cochins? He requires a breed that shall come early to maturity, and weigh heavily, and lay well; and in these particulars the Dorkings far surpass the "pet of the fancy." A Dorking pullet, hatched in April last (12th), within one hundred yards of the unfeathered Cochin above referred to, weighs, at this date, six pounds, and has laid eggs every alternate day for the past three weeks. *This is the breed* for the agriculturist; and the Society has acted wisely and well in their selection and arrangement of the prize list; for if a genealogy, stretching back for centuries, even far beyond the age of the learned Aldrovandi; if associations, classical as the Bard of Avon's writings can make them; if the authority of Pliny and Columella can outweigh the ephemeral opinions of the fashionable dandyism of the present day; or, what is far more to the purpose, if beauty of plumage, early maturity, great size, fecundity in eggs and chickens, whiteness, and delicacy of flesh, constitute claims for preference in the gallinaceous tribes, then, may the high-bred speckled Dorking calmly "abide its time," and treat with proud and becoming indifference the popular mania in favour of the long-legged, tough, tall, and tailless Cochin-Chinas. Such, at least, is the *modest* opinion of
Mickleover, Sept. 22, 1852. AMICUS GALLI.

FAMILIARITY OF BIRDS.

The Robin.—The nursery ballad on the "Children in the Wood," has done much for the protection of the Robin. He is a bird which never congregates, but is widely spread; and there are few localities in the country that are not enlivened by his presence. He is a general attendant on the gardener, particularly on the operations of the spade, in search of worms and insects. He is very familiar, and, if encouraged, soon becomes half-domesticated. For two or three years a robin formed one of my family; seldom did I sit down to a meal without his being on the table. He would enter the house by any door or window, and watch his opportunity to pass into the room as the servant brought in the dishes. At other times he would appear at the parlour window, and on being admitted, would fly to my knee, or perch upon the book I was reading; but his favourite post was the lid of a lady's workbox, and among its contents of bobbins and reels of cotton he would find great amusement. Upon this lid he would warble by the half-hour together, in soft, musical notes, which, at times, appeared to come from different parts of the room, as though he was a ventriloquist. He would feed from the hand, and was not disturbed by the movements of the family.

The Chaffinch.—Another of my familiar acquaintance was a hen Chaffinch, an almost constant visitor. One morning she brought, for my amusement, her little family of four young ones, and having arranged them in a row on the breakfast table, commenced feeding them. After their repast a difficulty arose; she wished to withdraw them, but they remained immovable, and it was interesting to observe her endeavours to accomplish this object, flying in and out of the room, and calling to them, but without avail. They appeared to enjoy their position, and were deaf to her solicitations; at length, one of them flew out, and the rest followed in succession.

The Jackdaw.—One day a female of my family, on visiting a neighbouring farm, brought home a young Jackdaw, which had been caught by a boy. He was turned loose in the garden, and but little thought of him. He grew up, however, very sociable, and though he had full use of his wings for six years, he never left us, and was found dead at last on the gravel walk, apparently killed by a stone. His first concern of a morning was to call me up, by tapping at my chamber window; he would then attend me in my rounds before breakfast, to pick up the earwigs, as they were emptied out of the flower-pots, placed as traps on the tops of the dahlia stakes. He invariably assisted in our garden operations, seizing the small worms, grubs and insects. During the day, his favourite resort was an elm tree by the road-side, and his great delight consisted in holding collo-

quies with the children as they went to, and returned from, school. He would visit the neighbouring cottages, particularly if any workmen were employed about them; would sometimes accompany his mistress to church, which he was with much difficulty prevented from entering, and became at length so troublesome, that on these occasions he was obliged to be shut up: if at liberty, he would watch for her return, and call to her the moment he saw her among the crowd. He would meet me on my coming home from a neighbouring town, and fly for a mile by the side of my gig, uttering "Jack." He would attend me in my country walks, sailing over my head, and alighting on some tree in advance to invite me onwards. When drinking tea on the lawn, he would testify his joy by exhibiting all manner of gambols, sometimes over our shoulders, sometimes hiding himself in the folds of a lady's dress, but generally ending in seizing a slice of bread and butter, and flying off with it. His faults were—his over-familiarity, and making too free with what did not belong to him. Few animals exhibited greater sagacity; he knew when he had done wrong; his life was a system of schemes and contrivances, and his death a family loss.

To those who are fond of studying the habits of birds, and whose position in life enables them to indulge in it, a delightful source of instruction and recreation may be found in cultivating their familiar acquaintance.

S. P., Rushmere.

TO CORRESPONDENTS.

PROLIFICACY OF COCHIN-CHINA FOWLS.—Mr. E. George, of the Rookery, Chaldon, says, "Being a breeder of light-coloured Cochin-China fowls, perhaps you will permit me to add my testimony in their favour, which I think your readers will allow the following facts to be. I have had seventy chickens, from one hen, since the end of February last, besides using some of her eggs in other ways, and one dozen now hatching; and, to my own knowledge, she has laid a double-yolked egg and a soft-shelled one within twelve hours. I have had a brood of chickens from eggs of a pullet hatched the middle of March last; cockerels of same age weighing above *nine pounds*; pullets six pounds; and others, a month younger, five pounds and three-quarters. As to their hardihood, I can only say the numbers we have lost in rearing does not amount to seven per cent., and nearly half of those have been accidents, such as getting into the wrong coops, and being killed by the hen, &c. Now and then a bird will gain weight even faster than those already mentioned: for instance, a cockerel, which I exhibited at Lewes, has continued to gain more than an ounce a day ever since."

HENS NESTS.—Mr. W. J. Beeby, of Chaldon, near Coulsden, Surrey, says, "Referring to former numbers of your periodical, in which it has been endeavoured to show the best place for setting eggs, allow me to remark that, having kept the Cochin-China fowls the last five years, I have set the eggs on the bare ground, in wooden boxes on the ground, and, lastly, in wooden boxes raised from the ground, and (by way of experiment) lined with kamptulicon, (a composition of India-rubber and cork); and I am of opinion that a hen will hatch equally well in either of the above situations, if comfortably placed—the number of chickens brought forth depending entirely on the health of the layers and sitters. Can you tell me whether there have been any of the Cochin-China fowls imported of a pure white colour, with top-knots? Fine specimens of this variety are to be had at Hong-Kong and Shanghai, as I am informed by a party who has been at those places." We have not seen or heard before of white Cochin-China fowls with top-knots. We saw a buff one the other day with a slight tuft of feathers on the head; but we think it was symptomatic of a cross in the blood of one of its parents.

DATURA JUST BLOOMING (*Greenhorn*).—In the first place, give it abundance of water all the time that it is in bloom, and, as we are so near the winter, cease watering altogether as soon as it is out of flower; the leaves will soon droop, and the plant will look deplorable for ten days or so, but you may smile the while. If the leaves do not fall in ten days after the drooping, pull them off, and let the plants stand naked all the winter, and, unless the green top branches begin to shrivel, you need give no water; but if they do, give the pot a good soaking, to keep the tops fresh for cuttings. Any time in March or April, when you have a cucumber bed at full work, cut down your *Datura* as far as you like—or say, at a venture, to within a few inches of where it began to grow from last season; then with a thick paint made with water, soft soap, a little sulphur, and a lump of clay, cover the whole body of the plant, and let this remain as long as you can—it is to kill and keep off insects. Every joint of the tops will make a cutting; but you had better keep two joints to a cutting when the joints are far apart—one joint at the bottom for roots, the other for leaves; and so, when the joints or eyes are close on each other, make the cuttings four or five inches long. They like a brisk bottom-heat, but not much water.

MAURANDYA BARCLAYANA (*Ibid.*).—It is a perennial, and it may be cut in a good deal, and taken up and potted, but not cut down altogether. Keep a foot or so of the main stem, or stems, and six inches of as many of the side branches as you can train without crowding; and if there be any very small branches near the root, keep all of them, and at their full length. You had better do all this cutting at once, but let the plant remain to the end of October. One of the greatest errors in gardening at the present day is cutting in, or pruning, any plant, except the very commonest thing—as a laurel—the same day, or the same week, as it is to be potted from the borders, or transplanted elsewhere; *Maurandya* particularly so, as they make such long wiry roots, with few fibres; but

few plants deserve to be kept from year to year more than they. They also want to be in a cool, airy place all winter, and not get much water until you see them grow away freely. We are going to keep all our old plants of *Maurandias*, *Lophospermums*, *Ecceumocarpus*, and *Cobseas*, this winter. We shall have them in different lengths, from one to ten feet.

FLOWER-BEDS (S. S.).—We are going to give plans of different kinds of flower-gardens, single beds, and angle beds, and groups; and, to open the way for all this, we only propose, at first, to engrave actual flower-gardens as they now stand, with accompanying criticisms and suggestions. Your plan will appear in the series as a good example of a very useful way of making the best of a limited space of ground; meantime, we shall file your letter, to see what we can do for what you want most.

CHRYSANTHEMUMS (Lora).—“How soon is it advisable to force them; I have a large stock, and grow for show in greenhouse only?” They stand no forcing. From the 15th to the 25th of October we have put those with earliest flower-buds into a house, with doors open at both ends night and day, and we gained nearly a week, which was a great feat.

GERANIUMS IN POTS (Ibid).—“These are intended for show in greenhouse; mine are already cut down, thinned, and kept outside. When should I take them to the greenhouse?” As soon as you see your well-arranged letter in print.

CINEBARIAS (Ibid).—“Some of my varieties, and all my *Flora M' Ivors*, show appearance of either dry mould or mildew on the leaves (which are most luxuriant). I have sponged the leaves, and removed the diseased plants out of the greenhouse into a cold frame; have I done right?” Quite right; keep them in a dry, cool air, and dust them with flowers of sulphur.

AGAPANTHUS UMBELLATUS (S. S. S.).—Take it up about the end of October, but March is time enough to divide it, unless you are in a great hurry, when you may take the spade any day in the year, and part it into single plants.

PLANTS FOR TRELIS (Ibid).—Plant one *Clematis montana*, one common *Honeysuckle*, one *Felicite Perpetuelle Rose*, then one *Japan Honeysuckle*, and the last a *Sweet-scented Clematis*, as permanent plants to cover your thirty feet of trellis. You did not say the height of it, but we have assumed ten feet high; then you may plant either duplicates of these, or any you may prefer yourself, to fill the whole length nearly at once, and remove them as our selection fills up. Plant the *Laurels* as far from them as you can, and keep them within due bounds. Your soil will do, but have it trenched, and use great quantity of water the first season; all climbers like it, and stronger occasionally.

SPRING BULBS AND BEDDING PLANTS (M. B. B.).—In the second week in May, 1832, we called, among other places, at Eaton Hall in Cheshire, and at Knowsley, near Prescott; and there, at both places, we found gardeners removing immense quantities of Crocuses, Tulips, Hyacinths, and all the principal spring bulbs, from the flower to the reserve garden, to ripen their leaves, and keep the beds free for the summer crops. Since then we have ourselves practised that plan, and also that of potting all, or most of these bulbs, and removed them in their pots as soon as their beds are wanted; and, upon the whole, we have come to the conclusion that it is best and easiest not to pot any of them, but to remove them the first rainy or showery day after they are out of bloom, to take special care of the leaves, and to keep the ground well watered as long as the leaves kept green. We have also removed spring border flowers, as *Auriculas*, *Polyanthuses*, dwarf *Phloxes*, and such like, in the same way. Any good plant that flowers in the spring may, under this system, be made a bed of. The first flower-bed we ever saw was a bed of *Posies*, or *Polyanthuses*. About the 10th of May you can remove a bed of *Hyacinths*, &c., and plant it the same day with *Verbenas*, or *Calceolarias*, &c., filling in the spaces between the plants quite well with autumn-sown annuals. Next day it will look quite as well as with the *Hyacinths*, and next week it may be in full bloom, according to the kind of annual used.

DOUBLE GLAZING (Y. J. Bailey).—We made double-glazed windows for the fruit-room, when common glass was 1s. a foot, and we liked it much. A double-glazed frame would be as warm as a single-glazed one with double mats on—one inch, or less space will do between the glass. When we hear where glass is to be had at a penny per foot, as lately stated in our pages, we shall return to the subject.

ARCHES OVER WALKS (H.).—Your plan is most excellent, and the best we know of for the display of hardy climbers. A walk seventy yards long arched over, the arches “nine feet apart, and about seven or eight feet high,” will look extremely well. Let the centre of the arches be full eight feet above the walk. The standards to spring the arches from should be six-and-a-half to seven feet high; from these, and on both sides of the walk, arches should spring along the line of the walk, as well as across the walk. Let us earnestly advise you to adopt this suggestion. Then use duplicate plants along the whole line—that is, begin with 2 *Clematis montana*, one on the right, the other on the left hand; then 2 *Japan Honeysuckle*, 2 *Crimson Boursault* rose, 2 *Clematis cirrhosa*, to flower in February and March; 2 old *Double Musk* rose, or some good old *Noisette* to flower in the autumn; 2 *Aristolochia siphon*, for their broad, handsome leaves, and for the sake of variety; then 2 *Felicite Perpetuelle* rose, 2 *Sweet Clematis*, 2 *Laura Davoust* rose, 2 *Clematis Hendersonii*, 2 *Solanum jasminoides*. The following *Roses* are also eligible for your purpose:—*Queen of the Belgians*, *Rampant*, *Princess Marie*, and *Myrianthes*, *Rivers's Queen*, and *Wells's White*, or *Madame d'Arbly*. Try also *Tecoma*, or *Bignonia radicans major*. We would plant “annual and perennial creepers” as *auxiliaries*, but not till after the principals had one season's growth. Then we would try *Gloire de Rosamere* rose at the bottom of the rose pillars; *Clematis Sieboldi* and *purpurea*, with their kind; *Ecceumocarpus*, *Passion-flower*, *Lophospermum*, *Convolvulus major*, &c.

GOLDEN-CHAIN GERANIUMS (Rosa).—This, and the *Flower-of-the-day*, are best propagated in the spring, and should not be kept in pots during summer. In winter both of them will require little water, and to be grown in good turfy peat.

ERYTHRINA CHRISTA-GALLI (Ibid)—This is also best from spring cuttings, just like *Dahlias*, when the old plants make shoots three inches long. We do not usually recommend gardeners.

VINES (Rhydy Gros).—“Your vines have rooted from the very top of the stem under ground.” This is well; encourage such habit. For your insects, look to our back numbers for advice at the dressing used at pruning time. If they commence operations on the foliage in the ensuing

spring, see to fumigations, and the use of sulphur, as repeatedly advised in these pages. You must be moderate in your crop next year, suffering merely the strongest shoots to carry a bunch. The long-rod system is certainly manageable, but the close spur system for us, on the whole.

PEACHES (A. B. G.).—See an article on root-pruning in page 380 of last volume; this will meet your case. The large yellow *Ecnotheras*, *macrocarpa* and *missouriense*, are hardy; but the best way to propagate them is to pot a few old stools, and frame them, and propagate as *Dahlias*. They may be raised from seed, also, sown early in February. *Verbenas* will doubtless keep in the way you describe, but beware of confined damp, and use stout cuttings.

PEARS CRACKING (E. H. F.).—Your *Althorpe Crasanne* cracks through a capricious soil—that is to say, one suddenly liable to drought. If you cannot transplant, apply a top-dressing in the end of April, consisting of three parts manure, and one part adhesive loam, nearly six inches in thickness.

PEACH AND NECTARINE OVER-LUXURIANT (A Cheshire Rector).—Your main stem should have been pinched when it had grown nearly a foot; it is now established as a glutton, or robber. If the rest of the tree is disposed to grossness, root-prune immediately. Watch the shoots produced by your robbers next June, and pinch them as soon as six or eight inches long, repeating it in July in the next growth.

GREENHOUSE (Rev. R. Blackburn).—Your plan is good, and will succeed. This kind of house, with some trifling modifications, is much wanted by the amateur. We would have sashes at front, to slide horizontally in a groove, in order to reach the pots with facility, as also for ventilation purposes. Be sure you have capacious ventilators in back wall, the roof of course fixed. We would have four in yours, which is 17 feet 6 inches long, each half-a-yard long, and six inches wide, placed close to the top. You will also do well to provide a canvass shade, with a penthouse at back to receive it. You had better have four or five vines; when they are so far from the roof they have a tendency “to draw,” or run upwards, and any attempt to oppose this will be well-nigh futile. If you have no piping in front, you may readily obtain another shelf.

PLANTS FOR AUSTRALIA (J. T. W.).—As for fancy things, like florists' flowers, annuals, or any other kind of plant that you like or admire, you will find them just as useful in Australia as if you were only going with them from Inverness or Aberdeen to Exeter. All the bulbs of South Africa, and all the greenhouse bulbs from Washington, to the shores of Patagonia, do better in Australia than in Devonshire; so you may take out any bulb, root, plant, or seed you can lay your hands on; but we must not say where is the best place to buy anything. It is perfectly useless to ask us, or any other authority, what are the best plants for Australia. Whatever plants you like best are sure to be the best for you, either here or in Australia.

TREES BEFORE A HOUSE (Subscriber from No. 1).—Your “good lady” evinces better taste than many whom we could name, that are satisfied with such common things as *Lime-trees* before their doors, near London; and as you want them more for ornament than for screens, let her, by all means, have something handsome, and more aristocratic—say a couple of *Scarlet* or *Dwarf Horse-chestnuts*, the handsomest tree in England while in blossom. Ask for it by the name of *Æsculus rubicunda*; and those *Thorns* which make an equal display with either their flowers or fruit, and you can cut them to anything, if need be: *Crataegus aronia*, with splendid yellow, large haws, that are good to eat; *Crataegus orientalis*, the *Mespilus orientalis* of Tournfort, also with eatable fruit of a coral colour; *Crataegus tanacetifolia*, large yellow fruit. Then the *pink* and *scarlet-flowering Thorns*, and also the *double-flowering* varieties, white, pink, or scarlet. They are the sort of trees for “good ladies;” while *Lime-trees* are very useful for screening shops and butchers' stalls.

FLOWER-GARDEN PLAN (C. M.).—Your plan will be engraved, and will appear in our series, with such remarks as will suit your inquiries. Your proposal of festooning the roses towards the centre is a new and distinct feature, of which we much approve.

PRESERVING GRAPES (Susan).—We have kept grapes until after Christmas, by allowing them to remain on the vine, giving as much air as the weather permitted, to keep them dry. Plants may be grown well in the same house, for directly the leaves of the vine begin to turn yellow they may be stripped off. Grapes keep longer on the vine than anywhere else.

GLAZING GREENHOUSE (E. E.).—Do not let the glass lap over more than one-eighth of an inch. We prefer the laps not to be close.

TAXODIUM SEMPERVIRENS (D. P.).—There is some doubt about the identity of this tree, which is a native of North-West America, and that which is native of New Zealand. It is spoken of in the Horticultural Society's Journal as *Sequoia sempervirens*.

CRAMP IN COCHIN-CHINA FOWLS (Ibid).—We are told that they are liable to this disease, but we have never witnessed it in our own yard, where they have dry, warm shelters, and are liberally fed. Your diet for them is good, and their roosting-place warm. Have they a covered dry place to shelter and busk themselves in when it is wet weather?

VARIOUS.—Novice will see he has been attended to.

SHORT NOTICES (J. B. P., Dublin).—You will perceive we have not lost sight of your request. We try to meet the case of every reader, so far as we know his wants and wishes, and never look upon anything as a trouble.

RUSTIC SEATS AND GATES (An Old Subscriber).—We shall be glad if any one will send us drawings of such as they think ornamental. We will not lose sight of this. *Nettles* can only be destroyed by being constantly cut down, and by sowing salt over them very thickly.

NAMES OF PLANTS (M. A. L.).—No. 1, *Nigella hispanica*; No. 2, *Ulnus campestris*, variety *variegata alba*; No. 3, *Phlomis fruticosa*; No. 4 too much shrivelled to be detected. The Weeping Willow (*Salix Babylonica*) is a native of the Levant, and introduced to this country in 1730. The Weeping Ash is a variety of the common ash, propagated by grafting upon it.

INSECTS (Margate).—The insects sent as infesting old papers, closets, &c., are the *Plinius holosericus*, a species which has quite recently been imported from Russia in dried skins. It has spread with amazing rapidity. It feeds on dried animal remains.—J. O. W.

LONDON: Printed by HARRY WOOLDRIDGE, Winchester High-street, in the Parish of Saint Mary Calendar; and Published by WILLIAM SOMERVILLE ORR, at the Office, No. 2, Amen Corner, in the Parish of Christ Church, City of London.—October 7th, 1852.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last twenty-five years, the average highest and lowest temperatures of these days are 58.7° and 41.8° respectively. The greatest heat, 76°, occurred on the 14th in 1845; and the lowest cold, 24°, on the 15th in 1850. During the period 101 days were fine, and on 74 rain fell.

BRITISH WILD FLOWERS.

BERBERIDS.—BERBERIDACEÆ.

CHARACTERS OF THE ORDER.—Sepals 3, 4, 6, deciduous, in a double row, surrounded externally by petal-like scales. Petals below the seed-vessels, either equal to the sepals in number, and opposite to them, or twice as many, generally with an appendage at the base in the inside. Stamens equal in number to the petals, and opposite to them; anthers generally with two separate cells, opening elastically with a valve from the bottom to the top. Ovarium solitary, one-celled; style rather lateral; stigma globular. Fruit berried or capsular. Seeds attached to the bottom of the cell on one side, 1, 2, or 3; albumen between fleshy and horny; embryo straight in the axis. Shrubs or herbaceous perennial plants, for the most part smooth.

BERBERIS: Berberry; Barberry.

GENERIC CHARACTER.—Calyx below seed-vessel, of six spreading, reversed egg-shaped, concave, coloured, deciduous leaves; the three outer ones smallest. Petals six, opposite to the calyx, and not much longer, roundish-egg-shaped, concave, spreading, deciduous; the short claw of each bearing internally two oblong, more deeply coloured, probably, honey-bearing glands. Filaments linear, flattened, blunt, opposite to the petals, but shorter, attached to the base of each. Anthers of two separate lobes, on the opposite edges of the summit of the filament, each opening by a valve, from the bottom upwards. Germen oblong-oval. Style none. Stigma single, globular, broader than the germen, acutely bordered, permanent. Berry oblong, blunt, of one cell, pulpy, opening at the top. Seeds two or three, oblong, cylindrical, erect, attached by short stalks to the lower part of the cell.

BERBERIS VULGARIS: Barberry; *Pipperidge Bush.

Description.—It is a deciduous shrub attaining the height of eight or ten feet. Stems upright, branched, bark ash-coloured, slightly grooved, yellow inside, armed with sharp thorns, usually in threes. The first leaves are reversed egg-shaped, finely tooth-edged. Stipules terminating in a hair-like tooth. Stem-leaves alternate, the lowest slightly lobed, with spiny teeth. Secondary leaves in pairs, oblong, and saw-edged, and between the lower leaves and the thorns are

smaller leaves. Flowers towards the end of the branches, in drooping bunches, or racemes, with a bracte to each flower-stalk. Petals yellow, frequently saw-edged, with two orange-coloured nectaries at their base. Anthers roundish and yellow. Stigma greenish. Berries at first green, but when ripe a brilliant scarlet, cylindric-egg-shaped, rather bent, with a brown perforated projection at the end, and very acid. Seeds usually two, rarely three, loose in the berry, except slightly fastened to it at the bottom, oblong, thicker at the top, smooth, reddish, and hard.

There are many varieties, some being without seeds; others with white, yellow, purple, or black berries.

Places where found.—In hedges, and on bushy, chalky-soiled hills.

Time of flowering.—May and June.

History.—Its British name is the Pipridge, or Pipperidge; the Botanical one, and its corruption, Barberry, being borrowed from the Arabic. When the anthers are thoroughly ripe, if the base of the filament be irritated with a pin, or a bristle, the stamen rises with a sudden spring and strikes the anther against the summit of the pistil, affording a remarkable instance of one of the means used to perform the important office of impregnation. This singular vitality of fibre, which we denominate irritability, and which is particularly apparent in such plants as are called sensitive, excited the attention of that very ingenious experimentalist Kölreuter, who observes that the cells of the anthers do not split open lengthways, but that the outer coat detaches itself along the edges of the partition, which separates the two cells, and raising itself up with the greater portion of the pollen adhering to the inner surface, finally faces towards the stigma; having the inner surface that fronts the stigma covered with pollen. It is by this beautiful expedient that nature has so completely succeeded in her object of fecundation by the emission of pollen; for by this mode of opening of the anthers the stamens have gained so much in length, that they are enabled to reach with precision the stigma on which they are to discharge their contents; had the cells opened in the usual way, the stamens would have been too short for their intended functions. And here we may well exclaim with Cowley,

“If we could open and inbend our eye,
We all, like Moses, should espy,
Ev'n in a bush, the radiant Deity.”

When a stamen has gone through this movement, it draws the petal to the base of which it is fixed a little toward itself, and this is the reason why, when we have suddenly stimulated all the stamens of a flower that was before nearly expanded, we see it half closed again. The anthers are insensible to stimulus; the filaments evince most irritability nearest their base. The phenomenon may be fully induced by a burning lens; and when the flowers are electrified, and sparks are drawn from them by the approach of a metallic body, the stamens immediately spring toward the pistil. If it could happen that during the season of bloom the flowers were to remain uninfluenced by adventitious stimulus, the stamens would continue extended at their wonted distance from the pistil, and no fecundation could take place. But let us see the means adopted by Divine Wisdom for insuring the fecundation of this useful vegetable. Each petal has near its base two oblong honey-bearing glands. Between every two of these glands a stamen is placed, so that whenever an insect (of which abundance present themselves in the course of a day, beetles, flies, bees, and wasps, seeking

their own food), attempts to extract the honey exuded by the glands, it must touch, especially the lower and most irritable part of the filament, upon which this organ immediately springs up and proceeds to cover with its prolific dust the upper part of the pistil. A process nearly analogous may be observed in *Aristolochia*, *Orchis bifolia*, and some few other indigenous instances: caprification has been long known to afford remarkable exemplification among exotics.

The leaves are gratefully acid. The flowers are offensive to the smell, when near, but at a proper distance their odour is extremely fine. Dishes for the table are often garnished with bunches of the ripe berries. They are so very acid that birds will not eat them, but boiled with sugar they form a most agreeable rob or jelly. They are used likewise as a dry sweetmeat, and in sugar plums. An infusion of the bark in white wine is purgative. The roots boiled in lye, dye wool yellow. In Poland leather is dyed of a most beautiful yellow with the bark of the root. The inner bark of the stem dyes linen a fine yellow, with the assistance of alum.

An opinion is entertained by many who deserve attention,

THE EDITOR OF THE COTTAGE GARDENER, AS ONE OF THE HONORARY SECRETARIES OF THE WINCHESTER AND SOUTHERN COUNTIES SOCIETY FOR THE ENCOURAGEMENT OF POULTRY, will be greatly obliged by subscriptions being forwarded to him. Every subscriber of five shillings or upwards, thereby becomes a member, and every one wishing to become a member is requested to forward his or her subscription immediately. This is desirable, because the amount of prizes at the Society's first Exhibition, to be held on or before the first of December next, will be increased in proportion to the Society's funds.

The following excellent classification, first arranged by the Birmingham Society, is that also adopted by THE WINCHESTER AND SOUTHERN COUNTIES SOCIETY.

<i>Spanish.</i>	<i>Polands</i> ; black with white crests.
<i>Dorking</i> ; single-combed.	<i>Polands</i> ; golden, with ruffs or beards.
<i>Dorking</i> ; double or rose-combed.	<i>Polands</i> ; golden, without ruffs or beards.
<i>Dorking</i> ; white.	<i>Polands</i> ; silver, with ruffs or beards.
<i>Cochin-China</i> ; cinnamon and buff.	<i>Polands</i> ; silver, without ruffs or beards.
<i>Cochin-China</i> ; brown, and partridge-feathered.	<i>Any other distinct breed.</i>
<i>Cochin-China</i> ; white.	<i>Bantams</i> ; gold-laced.
<i>Malay.</i>	<i>Bantams</i> ; silver-laced.
<i>Game</i> ; white and piles.	<i>Bantams</i> ; white.
<i>Game</i> ; black-breasted, and other reds.	<i>Bantams</i> ; black.
<i>Game</i> ; blacks, and brassy-winged, except greys.	<i>Bantams</i> ; any other variety.
<i>Game</i> ; duck-wings, and other greys and blues.	<i>Pigeons.</i>
<i>Golden-pencilled Hamburg.</i>	<i>Geese.</i>
<i>Golden-spangled Hamburg.</i>	<i>Ducks.</i>
<i>Silver-pencilled Hamburg.</i>	<i>Turkeys.</i>
<i>Silver-spangled Hamburg.</i>	<i>Guinea Fowl.</i>

SIR,—Take them as a body, gardeners are very droll dogs. They have the bump of obstinacy, and the bump of self-esteem. Gall and Spurzheim tell us that these bumps may be exchanged for other and better bumps, provided the party owning them will read or listen to advice. In plain English, if a conceited man leaves off being conceited, the bump of conceit or self-esteem would subside, and give place to the bump of inquisitiveness.

What strides the gardeners in moderate establishments would make, if they could once succeed in being desirous to learn, in place of having an idea that they know more than any body else.

Since I first had a gardener, now some twenty-five years ago, every one who has lived with me has had this unfortunate "bump of conceit," which has always been a great

sustained as they are by some facts, that the Barberry causes wheat growing near to it to be attacked by the mildew. On the other hand, there are many evidences that wheat may be grown in its vicinity without being so affected. It is quite certain that the yellow parasitical fungus found on the leaves of the Barberry, is not the fungus that is the cause of the mildew. They are not only different species, but of different genera; that on the Barberry being *Æcidium Berberidis*, and that on the wheat is *Puccinia graminis*.

The peculiar constituent of the bark of the Barberry, which renders it not only a powerful tonic in medicine, but useful as a dye, has been named *Berberite*. It was first obtained pure by M. Buchner, in 1835. He administered it to some of his patients, in doses of ten grains, and found it a powerful tonic. Berberite answers very well as a dye-stuff, giving a fixed yellow colour without any mordant. Chloride of tin improves the colour. When the cloth is previously impregnated with sulphate of copper, a beautiful greenish-yellow colour is obtained. With nut-galls the colour is yellowish-brown. (*Lindley. Smith. Martyn. Withering. Thomson.*)

hindrance to him in his work, and always, in my experience, ended in a change. My present gardener is as obstinate a dog as you can well imagine. I read very regularly and very carefully, week by week, THE COTTAGE GARDENER, and mark every thing I think worth notice, for my man, and at the end of the week, when I go round the garden with him to see what has been done, and what will require to be done, I hand him over your invaluable little work, offering to him some remark upon the various items which have been noted for his perusal. I always get the same answer—

"It's all very well for them gents to write, but I know a great deal more than they do. They only put things in their paper to mislead, and then of course when our master reads them, he sucks it all in for truth, and that's the way so many poor gardeners are turned adrift."

In vain I have told him, that Mr. Beaton, Mr. Errington, Mr. Appleby, Mr. Fish, and all the other parties who write in THE COTTAGE GARDENER, do so with a sincere desire not to mislead, but to instruct and encourage both the old and the young. I have even myself taken the trouble to follow out, under my own superintendence, some hints thrown out by your able contributors. Success has always attended my efforts, but

"A man convinced against his will,
Remains of the same opinion still."

And so it is with my man; and yet the man is industrious, but his industry is very often lost for want of that bump of inquisitiveness; and nothing, I believe, but a new race of men, will ever correct the evils and heart-burnings which must arise between master and man.

The life of a common working gardener is, I am quite aware, against an increase of knowledge. He labours from Monday morning to Saturday night, and has only Sunday to refresh and recruit his strength and ideas. I have tried a different system; I give my man four set holidays in the year. I send him on those days either to Kew, Chiswick, Regent's Park, or Rosherville Gardens, pay all his expenses, and tell him to pick up some new ideas, and come back as lively as a lark.

Last year, I sent him and his wife to the Crystal Palace, and desired him, as a matter of course, to look at all the new garden things there, with a view to his improvement, and my benefit. When he came home, I asked him how he liked the place, and what he saw, his answer was—"Nothing new of note in the garden line." And the only things he thought well of, were the warlike weapons! The man is young (only 32), but his ideas are fixed, and nothing seems to stir him up; and if I were to change him for another, I might, by trying to jump out of the frying-pan, just jump into the fire.

Now, what I want you to do, Mr. Editor, is to write pretty regularly some paper on this sad subject, for I know nothing more disheartening to a gentleman, than continually seeing new faces, without getting even a change of ideas.

If I were not engaged all day, and every day, in business, I would only have a good, honest, willing, steady, and hard-working labourer, rather than a man calling himself a gardener. Plain directions, and a little common sense,

would do much, for nature is always ready to give plenty, if due diligence is used.

Once more, therefore, good Mr. Editor, have the goodness to do your best to improve this obstinate race of beings, you would add to their happiness, and to our comfort as masters, and you would be raising your journal high in the scale of usefulness.

A CITY FRIAR.

SUCH is the letter we have just received from a gentleman whom we know to be a man of sterling sense, and an indulgent master, but we are glad in the conviction that there are not many cases similar to his own, for we have little power to help the employers of such gardeners as our friend endures. We cannot undertake the office of censor of gardeners, any more than we can undertake to educate them. All that we profess to do, is to prepare weekly information appropriate to the season, conformably to the best gardening knowledge of our time, and to answer such questions as are addressed to us.

That information, and the answers to such questions, are given by some of the best practical gardeners of the day; and we can state, without any possibility of contradiction, that whoever has adopted their recommendations carefully, never failed in obtaining his object. Now, if a gardener, who has had none of the advantages which are possessed by our departmental writers, thinks that he knows as much as they do, and spurns at the information they can give, we can only pity him as a man that of all others is most hopeless of being improved, for he is not only ignorant, but is ignorant of his ignorance. Such a man, perhaps, will be surprised to hear, that there is a correspondence continually being carried on between the most skilful of British gardeners, who seek from each other advice, and suggestions, and information, when they are carrying out new plans, and when they encounter difficulties. Such men come also to THE COTTAGE GARDENER'S pages, and one of the most distinguished of them has said that he never took up one of our numbers without benefiting by some of its information.

We claim no especial merit for this, because from the worst of publications some instruction must be gleaned. Above all, we have not the presumption to attempt to instruct gardeners. We address ourselves to the amateur, and we advise him, as in the case before us, never to attempt to *teach* his gardener. There are always modes of conveying our wishes, without making it conspicuous that a man does not know his business, and if he carried our wishes into effect, we should never enquire whence he derived the necessary knowledge, or what means he adopted. He may have plans of his own, and whilst we are quite alive to what results the master has a right to require, we are quite as sensible that as the responsibility of failure rests upon the gardener, the means to be adopted should be left to him. Mrs. Ashton Smythe, it is said, requires grapes in the desert every day of the year, and Mr. Sanders, the gardener at Tidworth, regularly supplies the demand, but his employer never thinks of dictating how it shall be done. If however, Mr. Sanders did not know how to effect such a succession, and refused to be instructed

how Mr. Fleming, of Trentham, accomplishes the same object, then we should say he failed in his duty, and was unworthy of his position.

COVENT GARDEN.

I MUST not forget that in my last paper I promised to refer more at length this week to several subjects that were only alluded to in the report of last. And of these, the first we shall notice are those varieties of fruits which are most likely to be soonest over, and which are not likely to come under our observations again this season. The *Hessle Pear*, which we referred to last week, and which we observed is not "Hazel," as written by Lindley, nor "Hessel," as in the Horticultural Society's Catalogue, is a variety which was first discovered at the village of Hessle, near Hull, in Yorkshire. It does not rank as a first-rate pear, nor is it to be compared to many others of the same season; but being an immense bearer, and a respectable-looking article for the popular eye, it is admirably adapted for market-gardeners and orchardists. The tree is of very graceful habit, having slender pendulous shoots, of a very dark-purplish-black colour, and may easily be distinguished from every other variety by its characteristic appearance. *Louise d'Avranches*, and not "Louise Bonne de Jersey," as it is now erroneously called, is one of the very best and most delicious of our autumn desert pears. There have been a few of them in the market during the week, but ere our next report is written their season will be over. It is generally stated, by writers on pomology, that the origin of this variety is unknown; and having been introduced to this country from Jersey under the name of "Louise Bonne," it was, to distinguish it from the old Louise Bonne of Dubamel, called "Louise Bonne of Jersey." But its proper name is *Louise d'Avranches*; and all who value correctness of nomenclature, may take my authority, if they think it worth taking, for stating that it was raised by a M. Longueval, of Avranches, and the original tree is still in existence in the garden Rue St. Germain, and now in the possession of M. Le Clerc.

Of APPLES there has been a good supply during the week, and the demand has been very brisk. Sorts, which the week previously made 2s. 6d. and 3s. per bushel, have last week been sold for 4s. and 5s. And who do our readers imagine is the cause of this great and sudden rise? The Michaelmas goose. "I could a sold twice as many as I had, sir, if I could a got 'em," said a salesman to me. "I never see things go off as they did, never, all *my* life." The sorts which were in the market were—*Emperor Alexander*, *Alfriston*, *Hanwell Souring*, *Golden* and *Winter Pearmain*, *Scarlet Pearmain*, *Nonsuch*, and many lots of mixed varieties.

The PEARS which have been most plentiful, are *Bishop's Thumb*, but they were generally very small, and inferior in quality, their flavour being styptic. *Swan's Eggs* have made their appearance, but only to a small extent; there being only a few bushels of them offered. Everybody knows the *Old Swan's Egg*, as one

of the most highly and peculiarly-flavoured of our old English varieties. The *Brown Beurré* is also among the arrivals of the week, and is now just coming into perfection. Many of our readers may not know, and a great many have never heard of this fine old pear. It is a French variety, which has been held in high estimation by the horticulturists, both of this country and the Continent for the last two centuries; but as it requires the protection of a wall to bring it to perfection, it is not so generally cultivated, nor so widely known as it would have been had it been better adapted to general cultivation in this country. The prices which pears have made last week are also considerably in advance of the former. The cold weather is now driving our London population from their summer to their winter quarters, and consequently the demand and consumption becomes every day greater.

There is nothing new in the way of PLUMS from what was recorded last week, except a few *Reine Claude Violette* or *Purple Gage*, a fruit, which some of our readers will perhaps be astonished to find me say, I prefer to the green gage. Whether grown upon a wall, or as a standard in a suitable situation, and allowed to hang till it is "dead-ripe," that is, till it begins to shrivel, it is one of the most delicious sweetmeats which the most delicate palate could desire; but it must not be confounded with the "blue gage," a very different and inferior variety.

There have been some very fine GRAPES exhibited during the week, and particularly a few bunches of large well-grown *Canon Hall Muscats*, which were sold at 5s. and 6s. per pound. The *Black Hamburgs* continue at last week's quotations.

CUCUMBERS have been very plentiful, and some of them very good and cheap. I observed a lot varying in length from twelve to eighteen inches, from 2d. to 6d., and 9d. each. FILBERTS plentiful, at 9d. per pound. TOMATOES, 4s. to 5s. per half-sieve, or 8d. per punnet, containing eight or nine large ones. CAPSICUMS, long red, 6d. per dozen. MUSHROOMS are very plentiful and very large, and fetched from 3s. 6d. to 5s. per bushel.

CUT FLOWERS are, of course, not so plentiful now as they were earlier in the season; they consist of both in-and-out-door plants. As an illustration, I shall give the following constitution of a large and handsome bouquet:—*Double White Camellia*, *Double Chinese Primroses*, *Geraniums*, *Scarlet Geraniums*, *Azalea indica alba*, *Mignonne*, *Heliotrope*, *Gardenia*, *Verbenas*, *Pinks*, *Saffron Rose*, and fringed round the outside with leaves of the *Oak-leaved Geranium*. Of the common kinds there are lots of *Dahlias*, *China Asters*, *French and African Mari-golds*, *Fuchsias*, &c.

Again we must leave much of what we should like to have noticed till another week. H.

The following is a list of the *Horticultural and Poultry Shows* of which we are at present aware. We shall be obliged by any of our readers sending us ad-

ditions to the list, and giving the address of the Secretaries.

HORTICULTURAL SHOWS.

- BURY ST. EDMUNDS, Nov. 26 (Chrysanthemums). (Sec. G. P. Clay, Esq.)
 CALEDONIAN (Inverleith Row), Edinburgh, Dec. 2.
 HAMPSHIRE, Nov. 18 (Winchester). (Sec. Rev. F. Wickham, Winchester.)
 LONDON FLORICULTURAL (Exeter Hall, Strand), Nov. 9+, 23, Dec. 14+.
 NORTH LONDON, Nov. 23, Chrysanthemum.
 SOUTH LONDON (ROYAL), Oct. 14+, Nov. 11+, Dec. 9+, 16.

POULTRY SHOWS.

- BIRMINGHAM AND MIDLAND COUNTIES, 14th, 15th, 16th, and 17th December.
 BRISTOL AGRICULTURAL, December 7th, 8th, and 9th. (Sec. James Marmont.)
 CORNWALL (PENZANCE), about a week after the Birmingham. (Secs. Rev. W. W. Wingfield, Gulval Vicarage, and E. H. Rodd, Esq.)
 DORCHESTER, Nov. 18th. (Sec., G. J. Andrews, Esq., Dorchester.)

† For seedlings only.

PINE-CULTURE—HAMILTONIAN MODE.

(Continued from page 6.)

In the last paper the subject was brought up to the matter of *glass*; heating being merely pointed at. We here resume it; and having stated Mr. Hamilton's amount of piping for a house to fruit one hundred plants, we may offer a few observations. It will be remembered that Mr. Hamilton uses a flow and a return pipe all round the pit, with the exception of the end farthest from the boiler, and these exclusively to warm the atmosphere of the house. Each five-feet bed, too, has its flow and return pipe; and if we understand Mr. Hamilton's observations correctly, the flow and return in each bed are totally unconnected with each other, or with the flow and return round the exterior. It may also be observed, that the latter is in two divisions,—the one passing along the south side, and the other along the north, unconnected; a flow and return to each; the only bond of connection being the boiler, or, rather, the iron pan before described, where it would appear all the pipes meet. The two delivery pipes for the atmosphere proceed out of the two sides of this pan, near to and parallel with the end of the house, and the two delivery pipes for the bottom-heat proceed from the front of the pan, and fall at once into a similar parallel, and thence turning right and left into the chambers, the return pipes being, of course, beneath them. It will be seen that by this arrangement there must, perforce, be a great preponderance of heat at the boiler end, which, indeed, is the case in most houses, and so far generally leaves in the mind an idea of incompleteness—something to be desired. We stay not here to offer suggestions as to the possibility of improvements; space will not permit; but merely point, as we proceed, to matters deserving farther consideration, and leave it to the mind of the ingenious reader to examine such portions of the subject.

VENTILATION.—Mr. Hamilton, in his descriptive account, has said nothing on this head; not, however, because it is unimportant. We must here offer our ideas. In all ventilation, as connected with horticultural structures, it is a practice founded on well-known principles, to provide both outlet for the heated air—presumed to be of a depraved character—and inlet of fresh or cool air, of course, pure; these at distinct levels. We need scarcely point to the fact, that such practice is based upon the well-known rarefaction of air by heat, whereby warm particles have a constant tendency to

ascend, and the cooler as strict a tendency to rush in and supply their place. These facts are so well known to our readers that we merely point to them. Of course, under such circumstances, the highest level possible naturally seems the most eligible for the outlet, and the lowest for the inlet. The apex of a span-roof is, indeed, the very point where the greatest accumulation takes place, and here we at once suggest some ventilators. This position in such a house is tolerably fortunate in another respect; beneath it is the walk or passage, and here the operator can work such ventilators with facility, by a rope or otherwise. In all cases, we would have the escapes of liberal dimensions. It has been, and still is a practice with many, to have sliding roof-lights, but this is bad practice, involving much breakage of glass and inconvenience; a sufficient ventilation may always be accomplished by the ventilators here alluded to. There are many ways of constructing, fixing, and working these things, and we may merely observe, that any mode which will permit them to be worked with facility, and so fitted as to be capable of graduation and of excluding the rain and wind, will suffice. In a house fifty feet long, and of the character before described, we should have apertures of this kind about every ten feet, presenting an area when wide-open of about half-a-yard in length, by a foot in width. It is seldom that they would be required wide-open; nevertheless, it is well to be provided for contingencies, especially if unprovided with a shade. It must here be understood, that we consider this the minimum amount of escape.

And now for the inlet, or admission of fresh air at as low a level as is consistent with other regulations. Modern practice recognises the propriety of heating fresh air on its entrance to the interior of the house, and there is little doubt that it is really expedient to do so. To this end, the heating apparatus in modern hot-houses is so arranged, that in general one or two pipes are so placed as to receive the cold air at its entrance; that is to say, the position of the piping is made to bear a relation to the front ventilators. In some cases, front sashes are used, and these are made to slide or to swing outward on hinges; but, it must be remembered, that there is no absolute necessity for front sashes in pine-culture. Be that as it may, there is sure to arise a necessity for piping at the front of the house, and advantage should be taken of this, to have at least one pipe just above the floor level, and the ventilators for admitting fresh air just opposite that pipe. We think it a very good arrangement where two pipes, a flow and a return, are wanted in front, so to arrange them, and the boiler level, as that the lower or return pipe may rest on the floor line. This pipe we would have partly enclosed in a trench, say half its depth, and this trench made waterproof, and of some eight or ten inches in width, might have a tap at one end, communicating with a cistern or reservoir, so as to fill the trench with water as often as necessary, whilst, at the other end, should be another tap, or plug, entering a drain, so as that the water at any time could be run off speedily. This we consider a most excellent plan, and not a whit the worse from its extreme simplicity; it is what we have formerly termed "a pipe in a ditch." The apertures for the admission of fresh air should, as before observed, be opposite the surface of this trench, and the air would pass through the body of the house or pit duly attempered with heat and moisture. One thing is very desirable, to which we before alluded, viz., the propriety of being able to graduate the front air according to circumstances.

Thus much as to the ventilation; and before quitting the subject, we must beg to recommend a canvass shade to all houses with a southern slope, especially if large panes of sheet-glass be used. This should, by all means, be fixed to work on a roller, after the manner of the

orchid-houses about the Metropolis. Whatever people may say about the pine enjoying plenty of solar-light, which is, doubtless, the case when in a very healthy condition at the root; still, there are a few hours daily, in hot periods, when such shade is of immense benefit, if only in preventing a too rapid diminution of air-moisture. But a judicious shading accomplishes much more, and the preservation of their beautiful green-colour, together with that milky-green tint, for which healthy pines are notorious, is an object connected not only with appearance, but with health itself.

It will be seen that Mr. Hamilton advocates heating by hot-water; and, indeed, when properly fitted, we see nothing more to be desired. As to the old smoke-flue for pine-culture, nobody ever dreams of it in these days. We do not say that pines cannot be grown by such a mode of heating; they assuredly can, and well too, if needs be; but what we must affirm is, that it involves more expense in the end, and more uncertainty; and is, of necessity, nearly as great a consumer, as producer of atmospheric moisture; without a liberal supply of which, it matters not what the mode of culture may be. Whether piping or flues be used, a due provision must be made for *air-moisture*. It is a very common practice to have flue-covers in the form of a sunken panel, such should be three inches in depth; for piping, metallic trays of a saddle-form, may be placed on the flow-pipe, or the pipes may be obtained with flanges, all of a piece; and these, too, must be made to hold a liberal amount of water. In all three cases, a permanent reservoir should be established, however supplied. Those who have a fall of water, and require much for other purposes, would do well to use a "hydraulic ram," which is, indeed, one of the most valuable adjunct a garden establishment can possess. We have had one in work here for some thirty years, and this constantly supplies the mansion, laundry, stables, gardens, farm-buildings, and, indeed, the whole premises.

Before quitting the heating portion of the subject, we must beg to advert to another point or two. In the first place, our advice is, be sure you have a liberal amount of *piping*; that is to say, secure heat enough and to spare. We would have an apparatus which would guarantee us 70° in winter, when the out-doors thermometer indicated 12° or 15° of frost. Some persons may think this unnecessary, but they may be assured that under-heating is a false economy—a sad mistake. When the house is short of heating surface, and hard weather occurs, there is a continual temptation to stir the fires, and the owner may rest assured that every stir costs money. We would so arrange matters, as that little stirring was requisite, and that two good fire-dressings in the twenty-four hours should, if possible, suffice; all the rest should be regulated by the ash-pit door. In these cases, care should be taken to secure a capacious grate that will hold abundance of fuel. Those who have to "pay the piper," need not be alarmed at these things; we are not going to advocate a greater consumption of fuel than other folks.

We know of a Rogers's conical-boiler, one of the smaller size, that has been working for some half-dozen years, and we will engage that it has constantly consumed nearly twenty per cent. more fuel than a capacious one would have done. The hopper for fuel is so small, that it requires feeding every two to three hours, and if not waited on as late as eleven o'clock on a winter's night, it is almost sure to go out. Here, then, is a case in point; the working such an apparatus as this for half-a-dozen years, would go far to cure any one of a predilection for small furnaces.

As to the *boiler*, we care little about that; too much importance has been laid on these things. The best we have ever had to deal with is a "Burbidge," and from the firm of Burbidge and Healy, in Fleet-street. This

is really so complete, as to leave nothing to be desired. It is on the reverberating principle; and the ash-pit doors, which slide on a round bar of iron, give the most complete command over the apparatus.

One thing, as connected with the heating, we had almost forgotten to name, and that is, the propriety of having sliders or openings in the walls of the chamber that contains the pipes for bottom-heat; these, when the bottom warmth proves too strong, may be opened for awhile, and the surplus heat discharged into the air of the house. By such means, the bottom-heat and air-heat may be made "to play into each others hands." Having now disposed of heating matters, structure, &c., we shall, in a future number, take up cultural details.

R. ERRINGTON.

BEDDING, HERBACEOUS, AND ROCK PLANTS.

The prettiest plant for a flower-garden, that I have seen this season, and one that is very little known out of London, is called *Gaura Lindheimeri*, named after some German of the name of Lindheimer, and is pronounced as if written Lyndhymer, with the accent on the *ei*. For those who are looking out for good herbaceous plants, here is one of the gayest, and although not yet proved, I am quite sure it will make as showy a bed as any plant we now possess of a light colour. It is now (2nd October) beautifully in bloom in my own experimental border, and I think we can always rely on it from early in June to the end of September. It will seed as freely as the poppy, and it is perfectly hardy. Here, then, is a treasure, a novelty, and a gay flower to the bargain. I received my plant of it from the Horticultural Society. Fellows of the Society are entitled, by long usage, to any little thing that can be spared from their garden; and many persons join the Society, not for encouraging the growth of cabbages, but altogether for what stray plants they can call for from the garden; and some members do call for things most outrageously, and say all sorts of things if their demands are not complied with by return of post or train; but since 1830, I never heard of any complaints of one member being favoured more than another, in this respect. On the other hand, many of the members think it below their dignity to ask for anything from the Society, and would rather see part of their funds expended in keeping a collector or two, in distant parts, searching for new plants. At present, the Society has no one "out" on such a mission, excepting the ninth-part-of-a-man who went out some time since to Oregon. My plant of *Gaura Lindheimeri* is not likely to ripen seeds this year, having been removed at the wrong time. Whether it is in the nurseries or not I have not heard; but there are several large plants of it in the garden of the Society, in the American ground, in patches, and the idea of making it into beds occurred to me the moment I saw it. The plants of it at Chiswick are two or three years old, and between two and three feet high; the upper half being covered with flowers in the terminal-spike fashion, every branch ending in a spike of flowers. The plant grows in a dense mass; the spike begins to flower from the bottom, and before it has done flowering at the top, some of the seeds are ripe on the lower part, just as the *Clarkias* and *Godetias* do. The plant forms a section of the same order (Onagraceae), as the *Clarkias*, *Enocheras*, *Fuchsias*, and the like. The flowers are pure white, starchy, and as large again as those of *Jasminum grandiflorum*, and the calyx is larger than usual, and of a deep pinkish-red colour, throwing a shade of French-white on the flowers as they tremble in the air; altogether very pretty and pleasing. If we go right with this new bedder, we need not have it above eighteen

or twenty inches high, or about the same size as a good bed of *Salvia chamædrioides*, and this is the only plant with which I can compare its style of growth and flowering, only that this *Gaura* will produce three spikes, or three times as many flowers as the *Salvia*.

One may be excused for erring in first experimenting on a plant for a new purpose. But the following is the way I would try our present subject. Sow seeds of it the first week in March, and as soon as the seedlings were up, give them as much air as to *Calceolaria* seedlings. Pot them first into store pots, and afterwards into single pots of the smaller size, and by the end of April they would be fit to plant out in a nursery-bed, or border. Here I would let them remain till about Midsummer, then I would plant them out into the flower-garden, where a bed of annuals were beginning to fade. When the white and red *Clarkias* are sown in the second week in April, they generally begin to look seedy by the last week in July, and this *Gaura Lindheimeri* would be an excellent substitute for a bed of white *Clarkias* in a regular arrangement of colours. Seedlings of the *Gaura* would be coming into bloom by that time, or if they were in full bloom, they would remove from the nursery-bed with no harm. Some persons would prefer keeping them in pots all the while, but that is too extravagant for half the world, because of so much watering, and too slovenly for any good gardener, for unless a gardener can remove nine-tenths of all his annuals, without hurt, from a nursery to a flower-bed, any time before they are in bloom, why, he may as well bundle up and be off to "the diggings." The second year there will be no difficulty in having the bed of *Gaura*, by treating the plant as a biennial. Sow it towards the middle or end of May, in the open ground, in the reserve garden, and if it should throw up for flower in the autumn, let the flower-stalks be cut off as fast as they appear. It will then be in good order to plant out next spring where it is to flower. After that, old plants of it may be divided every autumn or spring, so that the plants do not get too high for a bed, or, perhaps, seedling plants will be found preferable.

Salvia coccinea.—I saw plants of this old and long-forgotten *Salvia* in the same collection, and it is well worth being saved and propagated for bedding-out. The only other one of the genus which will remind gardeners of the aspect of this *Salvia*, is one that was common twenty years ago, and called *Pseudo coccinea*. But this old one does not appear to be so strong, and is a more close and freer bloomer.

I also saw a variety of bedding *Geranium*, related to the *Golden Chain*, but a much stronger, and a larger-leaved kind, with the yellow on the leaves paler. Where the *Golden Chain* succeeds, as it does at Shrubland Park, this will never be a rival to it, but where the soil does not suit the *Golden Chain*, this will be a good, indeed the best, substitute for it. They had no particular name to it. *Punch* was the best scarlet in the flower-beds here, and it stood the heavy rains better than *Tom Thumb*. There was also a fine large bed of the *Salmon Geranium*, and *Lady Middleton* was a great favourite, and preferred before either *Cherry Cheek* or *Judy*. There was a large bed of a neutral tint, made of *Verbena trifida*, a close grower, and greyish flowers, which are very sweet, and the kind is well worth growing, not for bedding, but for cut flowers for nosegays, to be used as flowers of the Heliotrope. The best new *Verbena* I have seen this year, for a distinct bed, was at Mr. Jackson's nursery, next door to me, it would make the best pink bed of all I have seen; the flower is a bright reddish-pink, with a large white eye; the plant was in a pot, but the habit appeared to be well suited for a bed, and the name is of foreign accent, *Madame Comonissam*, or some such word, for the tally was not very clearly written.

HERBACEOUS PLANTS.

The very best autumn-flowering plant of this description that I saw in the Society's garden, was *Funkia grandiflora alba*. In my younger days, *Funkias* went by the name of *Hemerocallis*, or Day Lily, and this white one, though not very new, is the very best of the family, and is, indeed, a conspicuous plant, well worth having; and flowering so late in the season, makes it still more desirable. There are two plants not altogether herbaceous, or shrubby, but something between the two as they stood in the borders; one is *Clematis tubulosa*, and the other my own great favourite, *Indigofera decora*. Both have received medals as green-house plants, but they are sufficiently hardy about London to stand out in the borders, and from what I know of them, both prefer a peat border. The *Clematis* stood as a thick bush, twenty inches or two feet high, and well covered with large light-blue flowers. I saw it in two or three other places this season, where it was not nearly so good, but the nature of the soil made all the difference. *Gentiana pneumonanthe* was in fine bloom in the American-garden, and there were several other species of the Gentian, all nice flowers for a mixed border; and there are several little shrubs, or half shrubs, that are equally suitable for such a place, and foremost among them is the old-fashioned *Comptonia asplenifolia*, named after Bishop Compton, the greatest patron of gardening and botany in his day. It is a North American plant, doing better in peat than any other way, with leaves as pretty as those of a fern; and *Clethra alnifolia*, another little American plant, requiring a damp peat-border, and seldom seen out of nurseries. I saw them both in the mixed borders at Chiswick, and I never saw them so much in character before. In the same borders were large patches of the scarce *Azalea procumbens*, which one hardly ever sees in these days out of botanic gardens; this is a native of the Grampian range, in Scotland, and it is said that at one time its place of growth was only known to the Messrs. Brown, of the Kinoul Nursery, at Perth, who made a better market of it than of the *Double Scotch Rose*, which was first obtained by them in that nursery, and I never saw it more flourishing than on this occasion, and I recommend it and *Epigaea repens*, another scarce plant, as pet plants for the American borders. A plant of the *Lilium giganteum*, of India, one of the most stately of all the true lilies, has been planted out here in the new American garden, and it looks as if it would do out-of-doors with us; and if so, it will be a match some day for the Pampas grass (*Gynerium argenteum*), which is not far from it in the same garden, and which I hope the Messrs. Dickson, of Chester, will be able to seed, and when Mr. Appleby calls there again, he would bring us up a large batch of the seedlings; indeed, it would be worth while to send out to Mr. Tweedie for a peck or two of the seeds of this royal grass. Mr. Tweedie was the collector who first sent it to the Glasnevin Botanic Garden, in Dublin; and as Mr. Appleby tells us (vol. viii., p. 414), that "unfortunately the Messrs. Dickson have not been able as yet to increase it," writing to Mr. Tweedie seems now the only chance we have of getting a stock of it for supplying the universal demand that is sure to be made for it wherever THE COTTAGE GARDENER is read. Does our friend Mr. B., of Philadelphia, know a correspondent in the south, who could send him a supply of the seeds? Let him and Mr. Low, of Clapton, who has dealt largely with Mr. Tweedie, run a race for this grass.

ROCK PLANT.

But grass or no grass, I must not run away from my little pet plants, till I make known the *best rock plant*, in England or America either; it is called *Polygonum vacciniifolium*. I saw it both at the Society's Garden, and at Kew, and there can be no mistake about it,

although some of us are disappointed at not seeing the flowers come out so gay and brilliant as they are given by Dr. Royle, in his "Illustrations of the Plants of India," where the colour of the flower and the spikes is a deep rose, but with us they put you more in mind of a red brick than of a rose; nevertheless, all the cottage gardeners in the kingdom must get hold of it. It grows as close as a carpet, and runs away "like anything," as Sam Slick would say. It only grows a few inches high, but it flowers all over, like a corn-field, in close spikes, three or four inches long, and that too all through the autumn, until the frost puts a stop to it. According to Dr. Royle, it grows up as high above the level of the sea as 13,000 feet, on the peaks of the Himalayas, so that no frost can hurt it here. It would soon carpet a bed for Rhododendrons, like *Musk mimulus*, or it would cover over rock-work, or blocks, or make an edging for any block bank, or cover bare places about a Swiss-cottage, like the common *Tutzan*. D. BEATON.

JOTTINGS ABOUT MATTERS OF TASTE.

Unity of Expression.—"And what about that cranky subject?" good-humouredly write and say many of our friends. "Just let us know the temperature and the soil, and the waterings, certain plants require, and leave us to give *expression* according to our fancy. Your greatest doctors disagree as to the veriest trifles in these matters; why should not I have a fancy of my own? If it pleases me, who has a right to interfere? And by what means can you demonstrate that your ideas, your tastes, your arrangements, are superior to mine?" I own there is great force in statements such as these. We all *will* form opinions of our own, and it requires time, observation, and thought, to alter us a shade in their validity. A man could hardly get along if he did not consider his own plans best in the peculiar circumstances. He must be orthodox. The mischief is that, going a step farther, he is apt to imagine that his *doxy* is the only orthodoxy, while all other doxies are heterodoxy. Would that these ideas were confined to gardening. They meet us in the most momentous affairs of life. In our little world of gardening they foster alike rude, independent action, and a servile, copying spirit. "Oh! such a design will be quite out of character with the rest of your grounds; it will neither contrast nor harmonise with anything." "Indeed! why? I don't see that a fine wheat stack even should be any disagreeable object on my lawn." Another will have beds of his own quite original in their form, and they are twisted and turned into all conceivable quirks and fancies, involving vast labour in making and keeping, and yet never can be made to present an imposing effect. "One arrangement is very striking at a certain place—I will have the same here." It matters not that one position may be on a hill, and the other in a valley—that shutting out may be required in one place, and opening up in another! Water in every shape is a delightful accessory in gardens and pleasure grounds; its very sight cheers—the noise of its gurgle, ripple, or dropping, tranquilises the mind. A gentleman has come from Versailles, or witnessed the unequalled *jet d'eau* at Chatsworth, and forthwith he must have a spirting miniature fountain in his garden, though placed in the highest ground in the neighbourhood, leading every visitor to ask in astonishment where the water comes from. No doubt, even in this respect, much may be done with water-rams and steam power; but if the natural position of the valley is wanting, the *magical* influence of a fountain will ever be lessened, if not destroyed.

Hence it is, notwithstanding all that has been said and written, that the expressions, "good taste, and bad

taste—refined taste, and vulgar taste," are a mere bewildering enigma, being interpreted by as many minds to mean as many different things. Hence, too, our most learned and able writers on taste, gardenesque effect, &c., speak so astutely about "*imitating nature—following nature—taking nature for our guide,*" this same nature being a very useful, somewhat undefinable "looming"—something for adorning a sentence, or clenching an argument. And yet how indefinite is the idea communicated. We know that in all culture of plants we must take our first teachings from nature, ponder over and endeavour to supply the *circumstances* in which plants, unaided by man, flourish the most; but there, in an artistic point of view, the matter mostly ends. Surely it is not intended by the "imitators of nature," that our park scenery is to be the *beau idéal* of a thick forest, that has received its planting from the winds and birds of heaven; that our pleasure grounds are to resemble untrodden prairie, or the thickets by the side of a tropical stream; or that our flower-beds and plant-houses should have their exact counterpart in the circumstances, as well as flowers that deck the mountain's brow, and peep through the tangled glade. All these have their charms, and will ever command admiration; but artistic loveliness—the seen and felt presence of the tending, training hand of man, and yet not offensively obtruded—constitutes the *delight* of the garden. Make the *position* and the *circumstances* connected with every demesne, however humble, the first principle, the ground work of all ornamental gardening operations; and instead of unmeaning combinations, or servile imitations, we shall have little Edens, as interesting as they are diversified. Follow out in such arrangements the *imitation-of-nature* principle, and our Paradises would become monstrous wildernesses, eliciting, after all, but little of the kindred emotions we experience in beholding more natural scenery, that has cost man but little money or labour.

True, the introduction of the wild and picturesque in garden-scenery is *sometimes* attended with the most delightful results. But several things are necessary to secure that result. First: The natural circumstances, as respects character and position, must be suitable. Secondly: The grounds must be so large, that the clearly artistic gardenesque, and the more concealed artistic picturesque, should not be jumbled together. A knotty, wrinkled, hollow pollard, filled with flowers, looks beautiful on a lawn, at some distance from an elegant mansion. An artistic vase looks best near such a house. The beauty of the one and the other consists in their being so separated, that the mind and the eye alike have space for repose, before contemplating their separate beauties. Place them in juxtaposition, and you destroy the peculiar interest of both. Contrasts of opposite styles do not interfere with; they even help, and are necessary to a higher style of beauty, to a more perfect *wholeness*; but then these contrasts must be gradual, not commingled or rudely clashed together; for as we can only contemplate one set of ideas successfully at one and the same moment, for the sake of a bewildering variety and contrast we lose all the benefits and beauties of a "*unity of expression.*"

I feel myself a very tyro in these matters, though convinced as to the general correctness of the inferences adduced. In proportion as civilization and refinement advance, it will be found that these *trifling things* will gain in importance. A good while ago, similar ideas were broached, when, in answer to inquiries, I endeavoured to define the meaning of the terms *Greenhouse* and *Conservatory*, mentioning that the first was a house for preserving plants in pots and boxes, while the latter was a habitation for exotic-plants, planted out in the soil. I endeavoured to shew that a higher style of beauty would be insured, by as much as possible

attending to these characteristics, and thus instead of confounding, promote "*unity of expression.*" I do not recollect if I instanced any facts in confirmation. Let me just mention what convinced me more fully *then*, and what still further confirms me *now*. At one of the Regent's Park Exhibitions, two years ago, the show of American plants was in full magnificence. One peep below the awning was a realization of the dreams of Fairy-land. Even the beauty of the ladies, dazzling as it was, seemed for once to be shaded. Much, no doubt, depended upon the beautiful arrangement, and the ground-plan so diversified, with bank and declivity, miniature hill and dale, but not a little also depended upon the fact, that *not a pot or box were to be seen*. As you traversed the regular exhibition-tents, unity of idea was again so far prevalent, that every thing had its pot, or box, or block, or basket; but when, after this you entered the beautiful conservatory, and felt delighted in examining the fine healthy specimens of growth, there was still a feeling of the *heterogenous* associated with the whole, and that mostly owing to the fact, that many of the best plants *were planted out*, while others stood in large pots, &c., while collections of small pots were so grouped in masses that the individual pots were easily seen. It does not become me to criticize the mode adopted there, or at the rival garden at Chiswick. Public bodies must frequently attend to *much* besides little matters in taste. Still, I think there are few but will own that if in the conservatory at Chiswick, while the side-platform, as now, is devoted to plants in pots, the plants in the centre bed were not *partially*, but *wholly* planted out, or so plunged with their pots as to seem to be so, that a higher style of beauty would be manifested, merely because a unity of expression was thus made apparent. The same facts struck me forcibly as respects the large conservatory at Kew, when I traversed it during the summer. I mention these, because the instances are well known, and because, from the great good that has been done by these Societies, and the influence they properly and deservedly exercise, whatever is done is noted down as an example by gardeners and their employers.

Now I have not seen many places where these simple ideas are *rigidly* carried out, but if I wanted any thing to convince me of their soundness, it would be my recent *glance* at the grounds, and the well-known large conservatory at Chatsworth. The very position of the building is a master-stroke of policy, combining all the advantages of unity of expression, with the pleasure derived from contrast, between the gardenesque, the picturesquely romantic, and the more purely artistic lineaments of the noble building; situated in an amphitheatre of wood (or seemingly so), peculiarly its own. Just fancy such a huge airy building, so attractive to the eye outside, by its stripes of blue and white painting, Crystal Palace fashion, set down near the Palace of the Peak, or in the middle, or even at the side of the highly-kept grounds, and imagine the bewilderment with which a stranger must contemplate the scene, purely from the want of *repose* between the different objects, the inability to grasp the whole at once. You come not, therefore, on the conservatory immediately on leaving the finer dressed grounds. You enter upon walks, which gradually become more picturesque, through the wooded hill, that overhangs alike the dressed grounds and the classic Derwent; these walks, as you traverse them, become more wildly romantic. Embosomed in one nook you see masses of fern—in others, and creeping over huge stones, some of the finer and hardy American plants; now you pass a huge boulder of rock—again, another that rocks at the slightest touch; and ever and anon you pass huge heights of these masses of rocks, piled securely and firmly, yet wildly upon each other, leading your thoughts back to the doings of the giant Titans of old, when they

rolled mountain upon mountain; and just when in the height of your enjoyment, and wondering where all this will lead to, the large conservatory, with its open area for flower-garden plants, bursts upon your view. Now, in the whole of this wild scenery you never see anything directly opposed to nature; but you never lose sight of the fact, that, the natural circumstances secured, the mind and energy of a human designer had accomplished the rest. The plants in the conservatory looked vigorous and healthy; a platform round the side was appropriated to smaller plants in pots. The whole of the plants in the vast centre were planted out, or seemed to be so. No huge tub, or dirty red pot, interfered with the fine base of a stem of one plant, or the graceful, drooping foliage of another. Here, as well as in the rest of the grounds, the beauty was enhanced from the felt "unity of expression" that prevailed. But I must stop.

R. FISH.

SEEDLING DAHLIAS FOR 1853.

A FEW rambling notes by a friend, who signs himself *Observer*, has been sent to me, and I know the writer to be not only a good and most successful grower, but also one of the best judges of the day of the Dahlia.

He says, "I have seen all the following, and can speak confidently of their merits. I begin with Rawling's *Lilac King*; this is one of the gems of the season; fine lilac; the centre is the summit of perfection, very symmetrical. It is with me No. 1.

"*Sir John Franklin* (Turner's).—This is very much in form and substance like the preceding, with all the properties of a first-rate Dahlia; colour, dark orange-buff.

"*Queen Victoria* (Wheeler's).—Yellow, edged with purple; form, first-rate, and very beautiful; the centre well filled up.

"*Brilliant* (Rawling's).—Bright scarlet of the finest form; centre well up; easy to grow; decidedly the finest scarlet Dahlia ever produced; first-rate in every point.

"*Lord Byron* (Pope's).—Is a flower I noticed at several of the leading shows; the form is first-rate; colour, a clear bright salmon.

"*Miss Caroline* (Brettell's).—White, tipped with purple; a flower resembling the *Marchioness of Cornwallis* Dahlia, but without its faults; every flower appears to close well.

"These six flowers are the gems of the season, and have received the bulk of the certificates. No amateur can mistake, if he wishes to grow the best six varieties for 1853.

"I now go on to notice about six more, which will comprise all I intend speculating in this year among the show varieties.

"*Plantagenet* (Turner's).—Shaded purple, very constant, and a good colour.

"*Bob* (Turner's).—Scarlet, rather flat in the face, not equal to Rawling's *Brilliant*; rather different in colour, but useful, as good scarlets are rather scarce.

"*Lady Dalrymple* (Turvill's).—Light, edged with pink; a flower well up in the centre; of good form; rather small, but useful.

"*Annie Neville* (Keynes's).—Light, edged with purple; well up in the centre, but rather deficient in outline, but useful from its colour.

"*British Queen* (Drummond's).—Light, deeply edged with purple. I have only seen a flower or two, but what I have seen were good; rather thin, and I should say difficult to close.

"*Mrs. Stein* (Stein's).—Shaded purple, rather small, but well formed; one I should grow for its novel colour and shading. It is a very likely show-flower.

"These are all the flowers I have noticed out of a great quantity exhibited at the shows, and I have attended many of them. The *fancy varieties* appear to have made very slow progress this season; in fact, there has been

very few shown. The best I have seen this year is *Mrs. James Rawlings*, a sort of puce tipped with white. The flower took two prizes at the Surrey Gardens. I liked it there very much.

"*Wonderful* (Keynes's) is a striped flower, one of the best striped varieties, and has taken several prizes. There should be a class for striped flowers, to encourage their production.

"*Unanimity* (Edwards's).—Another distinctly-striped flower. If a new class is made for stripes these flowers will be in demand.

"These comprise my observations on the new flowers. If these notes are of any use to your readers, I may be induced to give my opinion on the last year's flowers, as I have grown most of them.—OBSERVER."

I have very few to add to "Observer's" list; he is truly a correct observer, and our amateur friends, growers of dahlias, cannot do better than follow his advice. I pledge myself to the correctness of his descriptions.

Mr. Stein, of Highgate, has a promising seedling, a light scarlet, named *Robinson*, with great depth of petal, of good substance, and excellent form; the same raiser has also one named *Mr. Lockner*, a pinkish-lilac, novel in colour, good in substance, and of first-rate form.

Also, one named *Mr. Dickson*, a blush-white, smooth edges, well up in the centre, and of excellent form. The suggestion "Observer" makes, that he is willing to give his experience and opinion of last year's Dahlias would, we are sure, be useful and acceptable to the readers of THE COTTAGE GARDENER.

T. APPLEBY.

WORK FOR WET DAYS.

UNLIKE the last and several previous seasons, the present one seems likely to visit us with all the arrears of rain which our weather prophets told us was due from the dry winter and spring, which, if not followed by abundance of rains in June and subsequently, would have left our ponds, streams, and wells, lower than was ever known; as it was, they were very low, even in mid-winter, and still more so in May; however, there seems no reason to think that water will have to be carted at Christmas this season, as it was last, to places where it was only necessary to do so in the summer before. The abundant rains of the last month (to say nothing of the present one and what may follow) will certainly replenish all our fountains, and for some time to come the ground is not likely to lack moisture; but in the midst of all this wet weather, the question arises, What are we to do; since out-door work is no longer a duty that can be performed? It then becomes us to see what can be done to advantage under cover in those successional wet days we have been of late so often visited with.

Where there is ample shed-room, *the dung for mushroom-beds* may be prepared, and the beds made, spawned, and other work connected therewith done; not forgetting to look to those beds that are in bearing, or may be expected to come into use soon. These latter, if they have been enduring the drying influence of fire-heat in any shape, must be supplied with water at those parts most exposed. It often happens that a mushroom-bed is formed in some back shed where the stoke-holes are placed. Now these fires, though heating the structures on the other side, very often diffuse an amount of heat backwards sufficient to maintain the temperature of the shed several degrees above similar places where there is no fire. Now this is very useful, as, notwithstanding the healthy, fine mushrooms that are often gathered in the open air until very late in the season, sometimes to Christmas, still some little warmth is necessary to insure a crop at that time, and still more so afterwards. Now

a mushroom-bed made in such a situation, is often more productive than those in "the house" set apart expressly for them; so that the amateur, or he of small means, who has no better place than a corner of half-a-dozen square yards, may, nevertheless, try his hand with a fair chance to succeed in the culture of this capricious production. This vacant space we suppose to be bounded on one or two sides by the wall of the building; on the other sides some temporary erection must also be put up, to keep the dung, &c., from breaking down when looking at the bed, gathering the crop, &c. Where dung is plentiful, and a bed of this sort is to make, I do not like the plan of throwing aside so very much of the litter as is done in preparing dung for beds in a regular mushroom-house, where they are obliged to be made so thin; on the contrary, leave a considerable part with the dung, and in making the bed, let it be double the thickness of the others, about two feet is not too thick, but be sure the dung has been well prepared by frequent turnings, and until all the rank heat is driven off. Now this work may be all very well done on wet days; in fact, if the materials be all inside, it is, perhaps, better done at that time than in dry weather. The spawning of beds that have been made a few days, and have been left to prove their heating powers, may also be performed, and earthing them over may also be done at once; this, in addition to preparing dung, &c., for future beds, may form a very profitable employment for a wet day.

It has been customary, from time out of mind, to *rope Onions* and hang them up; and though some of our younger brethren may dispute the doctrine of their keeping better in that position than when lying on a shelf or dry floor, yet we are not quite sure our grandfathers were at fault here. A string tied tight about the neck of the onion is likely to prevent the escape of its juices through that channel, while the position the rope is usually placed in is certainly more conducive to its preservation than when it is, in an indirect manner, in contact with mother earth. We like an ordinary hay or straw band best for a centre; and care should be taken not to bruise the onions in the handling. And we have no doubt but those who compare notes will be led to say in March, that tied-up onions have kept better than others. This job may advantageously be performed on wet days.

Root crops may also be looked to. *Carrots* keep quite as well in an ordinary cellar when not packed into that close mass so common to some; in fact, I object to pack them at all until December, or when the moisture, which more or less accompanies a heap of most productions, passes off; they may, however, be looked to now, and any symptoms of decay, or decaying matter of other kinds, removed, so as to give no chance to putrefaction spreading through neglect. *Beet* and *Parsnips* we suppose to be in the ground still; but that most uncertain of all productions, *the Potato*, must be looked to, and that frequently, as report would seem to imply that the whole crop of 1852 is, in many places, fast approaching a state of dissolution; and, if we regard the opinion of the worst of those evil prophets who pretend to foretel future events, both the stock of the ensuing winter, and the seed of another year, will be a dead letter. Without going the length of fearing such a result, I must own that I have never seen the disease so bad as it is this season in this district; still I hope that a remnant will be left for us to try again, to see if this scourge cannot in some way be counteracted. All that can now be done with those potatoes which show symptoms of decaying, will be to pick out all the bad ones as they show themselves, and, after drying the others as well as can be done, to dust them with quick lime. This powerful agent is an antidote to most of the fungus tribe, to which this disease is said to belong.

Another job for wet days is the making and sorting of *Label Sticks* for various purposes; some very small ones may be prepared, and tied up in bundles, to name varieties of bedding-out plants, and others that may be potted off when spring comes round; larger ones, but of the same material, may be made for labelling seed pans and other uses, when something more than the mere name may be added. Then, again, large strong ones of the best enduring wood may be made for marking out the position of bulbs, and other unseen plants, that may be scattered over mixed borders; these, when not marked in some way, are apt to have the spade driven right into the centre of them when the border is dug; but a mere mark is not sufficient, better smooth one end of the stake, rub on a little white paint, and at once write the name with a pencil. If this be well-done, it generally lasts as long as the wood endures. These should be rather stubby than tall, as they are not wanted to show themselves conspicuously; but another kind may be made longer, to mark the varieties of kitchen vegetables sown and planted. These ought to be of such a height as to stand to be seen when the plants have grown considerably; for this latter purpose, rounded stakes, flattened and smoothed at one end, are as good as any.

All these, and many more duties, may be performed on wet days, to say nothing of that "ridding-up" of the sheds and other places, which, in spite of regular good keeping, require now and then "a thorough cleaning out."
J. ROBSON.

VINES AT BISHOP STORTFORD.

FINE flowers, fine fruits, and fine vegetables, form subjects for poets and painters, are eagerly sought after by the rich, and looked at with longing eyes by the poor.

A recent visit to Hampton Court, and to Bishop Stortford, has proved to me that there is no royal road to gardening. At Hampton Court, all the appliances of the public purse do not enable our Queen to have at her desert such grapes as are to be seen in a private garden at Bishop Stortford. The Hampton Court vine has been celebrated for nearly 200 years, as a *rara arbor*, and so it was, till others and better were to be found. I have no desire to detract from the splendid growth and excellent training of the Hampton Court vine, but when I find a private gentleman, of moderate means, and with a moderate man for a gardener, can beat the royal vine, I think I am justified in saying, there is no royal road to horticulture or to knowledge.

I will endeavour to describe to such readers of THE COTTAGE GARDENER as cannot visit the royal and the plebian vines, what I saw, for their benefit. The vineries at Stortford consist of two well-glazed, lean-to houses, each sixty feet long, eighteen wide, and sixteen high at the back.

In one house there are fourteen vines of the Black Hambro' kind, entering the house (by a very simple contrivance described below), not up the rafters, but half-way between the rafters, and so up the roof, consequently enjoying all the light which can be had under a glazed roof. Each vine has on it about fifty bunches of grapes, of an average weight of 1½ lb., and in size about a small pigeon's egg. The colour is perfect, and but for a little rust this year, finer grapes never was produced.

In the other house there are the same number of lights, and about the same number of vines of the Muscat kind. These vines enter the house precisely as the others do; there are, as nearly as possible, fifty bunches of grapes on each vine, and each bunch will, when ripe, perhaps average from 2½ lbs. to 3 lbs. The grapes are very large, very even in size, and very clean in growth. The vines in both houses are in perfect health, always feeding upon a rich dish, which does justice to them, and which they do justice to. The leaves are neither gross nor small, but clean, transparent, and full of health, each leaf seems the counterpart of its neighbour, and which set off the fruit quite as much as the fruit sets off them.

The stem of these vines, only ten years growth, is bright

and clean, and as thick as a burly yeoman's arm. There has been no rampant growth, and there is none now. They are pruned upon the short and close spur system, and growing, as if by order, an exact and moderate length. The houses in which the vines grow and flourish face the south, at an angle of forty-five degrees; they stand upon a steeply-sloping bank, and are planted in a well-drained and well-made bed, in such a way that they can be looked after, and trained with nicety and ease.

There is nothing royal in the houses, and nothing royal about the man who waits upon them. The houses are clean and sweet, and the man is civil, without servility. There is an air of order and industry about the place, that makes any thoughtful person believe that where there is a will there is a way.

At Hampton Court the vine is large and fully grown, and managed from its origin upon the long-rod system; age, however, begins to tell upon it. The grapes this year are small, and many bunches will never colour, and never ripen. The house is good in size, and clean, but grand as it is, and as it was, it will not compete with the plebeian's vine in Hertfordshire.

There is something refreshing to my mind in the retrospect; it makes one think how much a man may do who puts his shoulder to the wheel. To be up and doing is the way; never to be dashed, and never to be daunted; a no-surrender man is the man for me, and the British, when once fairly on the scent, succeed wonderfully, excel everybody, because they look far and near for information on any subject they take up. The French invent, and we perfect. The foreigner is full of theory; we are full of practice.

I am well aware there are many aristocratic vines which will compete with those which I have described, but the reader must recollect these aristocratic vines cost an aristocratic outlay; whereas these plebeian vines are tended by a solitary man, who must keep watch and ward over them from one end of the year to the other.

I ought to mention that the Stortford vines are not forced, but merely cared for. Each house is warmed by a flue, and these flues are only used in very chilly or very damp days.

If the foregoing is thought worthy of a place in your journal, I may, perhaps, take the liberty of entering upon a further correspondence at some future time.*—THOS. MOXON.

The above mode is adopted for admitting the stems of the vines into the vinery without holes in the brick-work. A broad plate of thick wood projects about a foot from the wall, a semicircular piece is cut out of this for the vine-stem to sink into, and the front lights can then shut down close upon the plate. In the above drawing, two windows are shown propped open, and one is closed. At Bishop Stortford vinery, a piece of wooden plate is fastened to each window, out of that the semicircular piece is cut, so that the plate shuts down upon the vine-stem, but causes all the front lights to project in a slanting direction, even when closed.

* The sooner the better.—ED. C. G.

THE CULTIVATION AND HARVESTING OF TOBACCO.

IN THE UNITED STATES.—Sow as soon as frost is fairly out of the ground, or even in February, if you can get a warm spell of weather sufficiently dry to enable you properly to prepare the seed bed. Select a warm, sheltered spot of virgin land, free from grass and weeds, dig it up lightly, and put the surface in very fine order. For a bed of twelve or fourteen yards square, mix a large wine glass full of seed with about a peck of fine wood-ashes, so as to divide the seed equally through it, that it may be more evenly sown. Sow broadcast on the surface, rake with a fine-toothed rake very lightly, and tread or roll the ground very firmly.

IN ENGLAND.—Sow in a bed, with gentle heat, about the 10th April, or, if only for a few plants, in a small box, or large garden pot, under a frame, with little heat, until the plants appear; but take care that the plants do not get long stalks, as that is fatal to a good plant. They should, when young, be as flat to the ground as possible; if they come up too thick, wait till some have got five or six leaves, when carefully prick them out, so as to give more room for the others to come on; when the largest leaves are about three inches long, plant out where they are to remain, not nearer than three feet apart—in light, warm, well-drained soil, not over rich; if artificially made, let well-rotted leaf-mould form a large portion. Keep the ground well stirred and pricked around it during the period of its growth. The chief ingredients it seeks are potash and ammonia; the latter it obtains in a large amount from the atmosphere, through its immense leaves. As soon as any of its blossoms show colour, break off the head of the plant, including also the small top leaves; this will soon increase the size of the leaves, but, at the same time, the plant will again make an effort to blossom, by throwing out side-shoots. As soon as these become about two inches long, or as thick as your little finger, break them all off. If the season is not too wet, the plant will now begin to open; the ground leaves first, and so upwards. But sometimes it will become necessary to let the plant stand till you have to break off a second set of side-shoots. In America, and in a large crop, you must judge by experience when the plant has the best average of matured leaves upon it, and then cut it down and hang it up in a large, open, and airy barn to cure; but in England, on a small scale, you had better strip each leaf as it becomes ripe, and only cut down what remains when you are afraid of a sharp frost. The small ground leaves generally turn yellow, and in wet weather get partially damaged; they ought then to be pulled; with a large needle and piece of twine, string them and hang them up to dry, leaving them so that air can freely pass between them, and in as airy a place as possible, but under cover from night air, dew, or rain. These leaves will cure light and thin, and make very mild smoking tobacco; the next set of leaves may, or may not, turn yellow, but will look blotchy and rather transparent looking; they may then be pulled and treated in the same way, and so on as they ripen; but seldom, if ever, the whole of the leaves will ripen in this country; so when you anticipate a sharp frost, cut the plant down, and hang it up also to dry. Now, cured tobacco always rapidly absorbs moisture from the atmosphere, and can only be handled when it has given a little, but it must now remain until every vein in the leaf has become *thoroughly dry*, and not a particle of sap remains in it; in this damp climate that may be a very long time. After it has once been thoroughly dry and crisp, watch the next change in the atmosphere, and as soon as it is soft enough to be safely handled, and the middle vein is not crisp enough to snap when bent, take it down and tie it in small bundles, or hands; put these, if on a small scale, in a box, packed evenly with the butts outside, press them moderately, when they will undergo a slight heat; but this is the most delicate and nice part of managing a crop of tobacco; on it depends, most materially, its good flavour, and six or eight hours neglect may injure the whole crop, indeed totally spoil it; on a small scale, however, it cannot suffer so much from the same cause; when fermentation once commences, it sets in with great rapidity; all that is requisite, is that a very slight warmth should be generated, then open it all, shake the hands in the air, so as to let off the heat, and repack it again lightly, or, if it is in the right

condition, you may pack it down as tight as possible into any barrel or box, and it will not heat any more; and the tighter it is packed the better it will preserve its flavour. The sweating gets rid of the bitter gum that coats it, and, when properly conditioned, it should have a fine fresh, fragrant smell, somewhat similar to new hay. The principle of curing tobacco is precisely similar to the correct principle of making good hay, or clover hay, only a more delicate operation. Clover, or grass, when partially cured, should always be put into heaps until fermentation takes place, give it then a good shaking out and airing, and it will never injure by heating in the stack; so with tobacco, only it must be managed with a little more nicety, as it changes its condition so rapidly with each atmospheric change. Nitrate of potass is the chief ingredient in its ashes. The stalk or stem of the plant is of no use except for manure, for which it is valuable for any of the cereal crops.

It is erroneously supposed by many to be a great exhauster of the soil, and to require very rich ground. The idea is a monstrous fallacy, based upon practical results, without tracing them to their proper cause. Rich ground will make a very heavy crop of inferior tobacco, but the finest tobacco that can be grown is upon a poor sandy virgin soil. The first and second season after clearing off the timber, when the plant can obtain a sufficient quantity of potash from the little vegetable leaf-mould that is on the surface, combining which with the large quantity of ammonia its extensive system of leaves enables it to absorb from the atmosphere, it forms the nitrate of potass which, with some silicates, forms the principal ingredient of its ashes. A wet season is the most fatal to tobacco, especially if water lies about the roots; for which reason a little side or very undulating ground will make the brightest crops.

LEYTON.

[The correspondent who has obliged us with this, says it is furnished by a Maryland tobacco planter, now resident, and for the last two or three years, in England, and, therefore, may be relied on.—ED. C. G.]

THE BEST FUCHSIAS.

ALLOW me to say a few words on the six best Fuchsias that are out. For the three dark with purple corolla;—First, take *Nil Desperandum*, *Clapton Hero*, and *Alpha*. These are the best three darks, so far as quality is the object. If size, then take *Orion*, *Don Giovanni*, and *Smith's Kossuth*. For the light, take *Banks's Conspicua*, *Ariel* (Banks), and *Princess* (Banks). These I have found to be the most useful light ones that are grown. Their quality I have tested, therefore, if your correspondent, "Lacy," has not them in his collection, I should advise him to secure them; they are reasonable in price. He may obtain all the varieties mentioned above, at Mr. Smith's, Tollington Nursery, Islington. If "Lacy" wants something nearer perfection than the Fuchsias I have noticed, he must stop till the spring of 1853. Then he may procure *Banks's Glory*—than which in dark Fuchsias there is nothing to equal it. The beautiful deep crimson of the tube and sepals, the corolla being a glossy violet purple, forms a most gratifying contrast. It has had the honour of six first class certificates at the principal shows this season. Likewise a white Fuchsia, *Lady Franklin*, is considered the best light-coloured. The tube and sepals being so pure white, and the corolla pinky purple; it is quite entering into a new class of Fuchsias. If "Lacy" procures these in the spring, he need not fear competition. There are a few others that ought not to be omitted, if a first-rate collection is wanted. I will name them at a future time.—R. WEATHERILL.

COST OF KEEPING COCHIN-CHINA FOWLS.

UNDER the impression that I had sufficiently trespassed on the space of your paper, and the patience of your readers, I had determined to trouble you no more; but Anster Bonn's last letter calls for some remark. I do full justice to her zeal, her intelligence, and knowledge of the good qualities of Cochin-China poultry—I admire her candour; but whilst I read with pleasure her remarks, and readily

believe she is fully impressed with the reality of all she states, I must, with all courtesy, be permitted to add, that I am not the least convinced that Cochin-Chinas have any right to the great superiority she wishes to claim for them; nor do I think that Anster Bonn, keeping only one *sort* of poultry, can enter into this comparative discussion with a mind as unprejudiced as one who, like myself, keeps several sorts of what are supposed to be the best poultry, and who (only wishing to arrive at what is really the best breed) has no prejudice or partiality to gratify.

When Anster Bonn *did* keep *other* poultry, by her own account they were "indifferent Dorking, Spanish, a mixed lot, &c.;" but in my case I claim to have some of the best Cochin-Chinas in England, bred from Mr. Sturgeon's and Mr. Andrews's best birds—not (as Anster Bonn hints) "with length of leg, and upright gait," likely to have any cross of Malay; but short-legged, good in colour and shape; and as you, Mr. Editor, have seen my birds, you will give me credit for not decrying Cochins from envy. I agree perfectly in many of the good qualities advanced by Anster Bonn in favour of her feathered friends—I admire their laying powers, their docility and their *early maturity*; but even on this last point something may be said. I have heard (and am inclined to believe) that an opinion is gaining ground with some of the oldest, most experienced Cochin-China fanciers, that if this poultry does come into use earlier than other fowls, so they go out of use proportionably earlier. If this proves to be so, one of the great merits claimed for them is much weakened. Time must prove this. I am inclined to attach great weight to this opinion, coming to me from the quarter it did.

Anster Bonn, *even*, cannot defend the size of their eggs. I heard remarked at the breakfast-table the other morning, when some Cochin-China eggs appeared, "Do you call *these* eggs? Why, I could eat a dozen of them!" As for myself, I can sympathise with others, I have detested eggs ever since having been let in for a "horrid thing," I was comforted by hearing that I had *only* eaten for a "breakfast egg" what was called a "dinner egg" (an abomination of six weeks old).

Two points must remain in dispute between Anster Bonn and myself:—The quality of Cochins as table fowls; and the quantity of food they consume. The first must be always a matter of taste. I have now tried several, and *still* think they are not equal to *any* Dorking (Mr. Baily's, or anybody's). Of the dinner to which Anster Bonn alludes I had heard some rumour; and I do not doubt Anster Bonn's kindness and candour will induce her to inform us, whether the general opinion in the dining-room was pronounced as decidedly in favour of the Cochin-China as she tells us it was "out of the dining-room." I have heard a whisper it was not so.

Anster Bonn's statement as to the expense of food of her fowls is to me perfectly astounding. "One penny a week per head!" It strikes me, either that I (from being, I suppose, a friend to the farmer) have been paying too much for my corn, or that there is a "screw loose" in the domestic economy of my poultry-pard. I have never kept any correct account of the weekly expense per head, but in a rough way I have *supposed* it to be from 3d. to 3½d. per head weekly (unless with the *run* of a farm-yard, when it would be much less), for common fowls, and more for Cochin-Chinas.

I have heard several remarks of—"A penny a-week, indeed! Ridiculous! Much more like a penny a-day, &c." I offered an old woman, who *walks* some of my fowls, a penny! twopenny! threepenny! a-week. She refused them all.

A poultry dealer of my acquaintance puts it at 2½d. a-week. "But then, Sir (he added), I can get my stuff cheaper than you." I am determined, now, to put this to the test. I have confined two lots of fowls (each consists of one Cochin-China cock, and two hens) in two separate yards. A quantity of food had been weighed previously, in separate boxes, for them. From these they will be fed, and as what is left at the end of the week will be weighed, I can ascertain to half-an-ounce what the consumption of food has been, and your readers shall be acquainted with the consumption, the cost, the number of eggs laid in the time (and their joint weight), and they may then form their

own opinion. These *lots*, having no grass in their yards, will be furnished with green meat, *gratis*.

I am also trying the same experiment with our Cochinchina cockerills at a distance (the results of which you shall hear), and I intend to try the same also with some Spanish poultry.

I will take every care that the trial shall be conducted with the most perfect fairness, and I feel great interest in the result.

I have no leaning one way or the other. I have no object to gain, or prejudice to gratify. I really wish to ascertain, which is the cheapest and most profitable fowl to the cottager. And whilst gladly acknowledging the many merits of my friends, the Cochins, I honestly believe, that as being somewhat of a novelty, they have taken a higher perch in the poultry stage, than they are entitled to, or than they will retain. In the words of the old farce—"I may be wrong, but that's my opinion." But should further experience prove the error, no one will more cheerfully proclaim it, or more humbly acknowledge it than GALLUS.

TO CORRESPONDENTS.

** We request that no one will write to the departmental writers of THE COTTAGE GARDENER. It gives them unjustifiable trouble and expense. All communications should be addressed "To the Editor of the Cottage Gardener, 2, Amen Corner, Paternoster Row, London."

HOLLYHOCKS.—A very trustworthy correspondent at Durham writes as follows:—"I received the following from Mr. Chater, of Saffron Walden, and they have undoubtedly thrown all the other varieties into the shade:—*Comet* (Chater), ruby-red, large; *Joan of Arc* (Parsons), large, bluish; *Lady Braybrooke* (Parsons), crimson; *Magnum Bonum*, maroon; *Meteor* (Bircham), crimson; *Pulchella* (Chater), pink; *Saffiano* (Parsons), pinkish salmon, a splendid flower; *Triumphant* (Parsons), pale primrose, flower very full; *Spectabilis* (Chater), shaded salmon; *Walden Gem* (Chater), ruby-crimson; *White Perfection* (Chater), splendid white; *Mr. C. Barron* (Chater), pinkish salmon. As the Hollyhock has only lately been introduced into the north as a show flower, I think your numerous readers here might be benefited by such lists from amateurs who have grown such flowers, besides being aware that the information is sent by individuals that have no pecuniary interest to promote by making false representations." We shall most readily insert such lists, and any amateur sending us such a list of flowers which he has cultivated and approves, will greatly oblige us. We are obtaining similar lists from professional gardeners, and begin to-day with the *Dahlia*.

ROOKS.—In reply to P. P., who wishes for information as to the most practical way of establishing a rookery, I beg to state, that the first settlement of rooks upon our property was effected by conveying a nest of these birds, when the young were hatched, and fixing it securely in a tree. My sister gave a daring boy a trifle to take the nest, and place it in its new position, from which small beginning a rookery has sprung. I believe the rookery from which the parent nest came was that upon a neighbouring estate, a very few fields from what is now our own; so that the old birds could easily follow the cries of their young. This took place so many years ago, that I do not remember exactly from whence the nest was brought; but if it did not come from the nearest rookery, it must have been from one seven or eight miles off, which I think scarcely possible. Beech and elm are the trees preferred by rooks; our own never fix upon the oaks and limes that stand close to their settlement, but remain exclusively attached to the tall beeches.—R. F. I.

DOUBLE AND SINGLE FLOWER-BUDS.—*Senilis* says, "At page 424 of the last volume, I read, 'We know of no test whereby to know a double from a single Hollyhock before the blossom opens, except that the flower-buds of the double are more globular, and larger.' This leads me back fourteen years, next January, when two of the best and most celebrated *Camellia* growers in England (nurserymen) came to see my *Camellias*. Among other plants, I had a beautiful specimen of a seedling *Camellia*, then in full bud for the first time, but none of them were expected to open before April. The plant had all the appearance of turning out one of the best seedlings of that period; the leaves were as thick and round as those of the old double-striped, or variegated; the young wood was stout and short-jointed, and the buds were as large and round as any in the house at that stage of development. My visitors made an offer of ten guineas for this plant, and would "take all chances;" but no! the offer rather turned me the other way. Still I regretted that I did not know of a test whereby to know a double from a single *Camellia* thus early. A young German, who overheard our conversation, the offer, and my regret, grinned from ear to ear, but said nought until the visitors departed, when, after a little fishing, I got out of him the secret how any flower-bud could be proved as being that of a double or single flower. Cut the bud through the middle, and the secret is out to view—a single folding round the stamens; the double all folds and no stamens. How very simple! but well worth knowing."

TEA-SCENTED ROSES (Q.)—In very severe weather it is a good plan to cover them with a mat, as you propose; and if you could get moss enough to cover the whole surface of the bed an inch or two, and then stick a lot of small, dry branches, such as the tops of pea sticks, in among them, the frost will not harm them, even in so young a state. Dry sticks, if they are placed thick enough, are much better for protection than boughs of evergreens.

FUCHSIA SPECTABILIS (W. S.)—We are not aware that it has been exhibited at any of the shows, and the less that is said about it the better. Perhaps some of our correspondents could give directions for its

culture. We have one blooming well in a warm border, the pot being plunged there all the summer.

GLOXINIAS (Ibid.)—As your plants have made no bulbs, you must not let them get quite dry this winter, else they will slip through your fingers.

CANTUA DEFENDENS (W. S.)—A warm house was sure to play vengeance with it. The very coldest part in the front of a cold pit, where the sun and frost could not reach it, is what it likes.

HICKORY NUTS (H. R. L. N.)—You have brought some Hickory Nuts (*Carya*) with you from Canada, and wish to know the best mode of culture, and in what soil they should be grown. Preserve them in sand, in a cool cellar, and sow them in rows thinly, in the spring, about the end of March. The soil they like is a strong loam, deep and rich, and well drained. Allow them to remain in the seed-rows for two years, then transplant them in October, into nursery-rows, and after the second year transplant them finally where they are to grow to be trees.

PLANTING CONIFERS (M. S.—, Wigan)—You will see Mr. Appleby has answered your queries in several back numbers. If you noticed rightly, the season for planting is mentioned by him to be, *first*, August and September, and then March. The grand object to aim at, should be to plant them at such season as will allow them time to force new roots before the early frosts of winter and the dry weather of spring. The state of the season, whether autumn or spring, will have influence upon the planting. If wet and cold, wait till it is moderately dry and warm. The small bit of a plant you sent we cannot make out. Send it again when in bloom.

BEES.—B. B. says:—"Since I sent you my statement (see pp. 15-16), I have observed in hive No. 2, that the drones are *not* all destroyed, three or four made their appearance on the 26th of Sept., and about the same time from eight to ten bees arrived with bee bread. I have always been led to consider the appearance of drones at this time is a bad sign. If it be really so, how would you have me act? I have been feeding the bees in this hive for the last fourteen days."

WINTERING SCARLET GERANIUMS (B. B.)—Your frame filled with coal-ashes will do excellently to plunge the pots in; and as you have them already cut back, you will have nothing to do but to admit air to them freely whenever the temperature permits, and to exclude frost by covering the glass with hay and mats. The same treatment will exactly suit your *Verbenas*.

THOUSAND-HEADED CABBAGE (Doncaster)—For late spring-feed for sheep, sow early in March, prick the seedlings out when three inches high, and plant out finally early in July. You may continue planting out throughout August and early September, as more ground becomes vacant. Plant in rows, three feet apart each way.

PLANTS FOR FLOWER-BEDS (Ignotus)—We hope to begin the publication of plans next week.

PINE-CULTURE (Stupid)—You will have all your queries answered in Mr. Errington's papers.

APPLES (B)—Six *Desert Apples for Espaliers*, good bearers and good flavoured, are Lamb Abbey Pearmain, Kerry Pippin, Old Nonpareil, Scarlet Nonpareil, and Sturmer Pippin. Six *Kitchen Apples for Espaliers* are Hawthornden, Alfriston, Wareham Russet, Blenheim Orange, Keswick Codling, and Waltham Abbey Seedling.

LABURNUM NOW BLOOMING (A Subscriber)—It is not at all uncommon for untimely blossoms to appear on this tree.

WHITE COCHIN-CHINA FOWLS.—*Aliquis* wishes to know where, and at what price per pair, he can purchase these. You will see two advertisements of them in our last number.

SPANISH CHESNUT SEEDLINGS (T. M. W.)—These are quite hardy, and will require no protection.

TOBACCO CULTURE (A Friar)—See a very full and excellent paper on the subject in our present number.

AUTUMN PLANTING POTATOES (J. R., Everton)—Dig all your light soil over in November, and plant as it is dug; that is, as soon as space enough is dug for a row plant the sets with a dibble, six or seven inches deep, and do not let the ground be trod upon afterwards. Do not add manure of any kind, but in March sow over the surface Epsom Salt, at the rate of three pounds to every hundred square yards. Do not plant any but the earliest ripening kinds; the Kemps are too late.

BACK NUMBERS (Omega)—If you send as you propose, you can have the numbers and the volume bound. Send a note with them, stating what you wish, and your address. Other questions next week.

ADVERTISEMENTS (A Watcher)—It is quite impossible for us to answer for the truth of statements in advertisements. We should have a nice time of it if we had to test the worth of everything advertised. If we are especially asked for an opinion upon any one article, we can do no more than obtain relative information, if possible.

DISEASES OF POULTRY (Ibid.)—You will confer a great favour by communicating your observations upon this subject.

FORGET-ME-NOT SEED (Ellen)—Perhaps Mr. Carter, Seedsman, High Holborn, London, can supply you. Have any of our readers some seed of this flower sacred to remembrance?

PURPLE-FLOWERED CLIMBER (A Subscriber)—This which you saw against the wall of a villa at Torquay, we have little doubt is *Ceanothus azureus*. It is highly ornamental, and the more to be prized because blooming in autumn.

THE LONDON MANURE COM-

PANY beg to offer as under:—
Corn Manure, most valuable for spring dressing, Concentrated Urate, Super-Phosphate of Lime, Nitrate of Soda, Sulphate of Ammonia, Fishery and Agricultural Salt, Gypsum, Fossil Bones, Sulphuric Acid, and every other artificial manure; also, a constant supply of English and Foreign Linseed Cake.

Peruvian Guano, guaranteed the genuine importation of Messrs. A. Gibbs and Sons, £9 10s per ton, or £9 5s in quantities of five tons or upwards. **EDWARD PURSER, Secretary,** 40, Bridge Street Blackfriars.

THE ROYAL EXHIBITION—

39, Albemarle Street, Piccadilly, observe, opposite the York Hotel.—Valuable newly-invented, very small, powerful, Waistcoat pocket Glass, the size of a Walnut, to discern minute objects at a distance of from four to five miles, which is found to be invaluable for yachting, and to Sportsmen, Gentlemen, and Gamekeepers. Telescopes, possessing such extraordinary power, that some 3½ inches, with an extra eye-piece, will show distinctly Jupiter's Moons, Saturn's Ring, and the double Stars. They supersede every other kind, and are of all sizes for the Waistcoat pocket, Shooting, Military purposes, &c. Opera and Race-course Glasses with wonderful power; a minute object can be clearly seen, from ten to twelve miles distant. Invaluable newly-invented Spectacle.

Deafness—New Discovery—The Organic Vibrator, an extraordinary powerful, small, newly-invented instrument, for deafness, entirely different from all others, to surpass anything of the kind that has been, or probably ever can be produced. Being of the same colour as the skin, is not perceptible; it enables deaf persons to hear distinctly at church and at public assemblies; the unpleasant sensation of singing noises in the ears are entirely removed; and it affords all the assistance that possibly could be desired.

S. & B. SOLOMONS, Aurists and Opticians, 39, Albemarle Street, Piccadilly. Observe, opposite the York Hotel.

Lately published, price 5s 6d.

MRS. LOUDON'S WORKS ON BOTANY AND GARDENING.

New Editions, Revised and Improved.

These Volumes contain beautifully Coloured Drawings of above seventeen hundred of the choicest species of Garden and Greenhouse Plants and Wild Flowers, with descriptions, and full directions for cultivation.

In 4to., cloth lettered, price £1 15s; half-bound morocco, gilt edges, £2 2s.

THE LADIES' FLOWER-GARDEN OF ORNAMENTAL ANNUALS. In Forty-eight Coloured Plates, containing upwards of Three Hundred Figures of the most showy and interesting Annual Flowers.

In 4to., cloth lettered, price £2 2s; half-bound morocco, gilt edges, £2 10s.

THE LADIES' FLOWER-GARDEN OF ORNAMENTAL BULBOUS PLANTS. In Fifty-eight Coloured Plates, containing above Three Hundred Figures of the most desirable Bulbous Flowers.

In 4to., cloth lettered, price £3; half-bound morocco, gilt edges, £3 8s.

THE LADIES' FLOWER-GARDEN OF ORNAMENTAL PERENNIALS. In Ninety Coloured Plates, containing Five Hundred Figures of Hardy Perennial Flowers.

In 4to., cloth lettered, price £1 11s 6d; half-bound morocco, gilt edges, £2.

THE LADIES' FLOWER-GARDEN OF ORNAMENTAL GREENHOUSE PLANTS. In Forty-two Coloured Plates, and containing about Three Hundred Figures of the most desirable Greenhouse Plants.

In 4to., cloth lettered, price £2 2s; half-bound morocco, gilt edges, £2 10s.

BRITISH WILD FLOWERS. In Sixty Plates, containing Three Hundred and Fifty Species, beautifully Coloured.

London: Wm. S. OER & Co., Amen-Corner.

BASS AND BROWN'S NEW AUTUMN CATALOGUE is now ready, and will be sent free on receipt of Three Postage Stamps.

BEST NEW GERANIUMS OF LAST SEASON. Strong Plants now ready. **BASS AND BROWN** have the pleasure to offer, as under, the following, all new varieties, of last season, raised by Messrs. HOYLE, FOSTER, and DOBSON. The Collection may be had for £3 15s. Any 12 for 50s, or left to our selection, for 44s.

For Varieties of Previous Introduction, see Catalogue. Our Annual Importation of Dutch Bulbs has arrived in excellent condition. We also beg to call attention to our very superb collections of Ranunculi, Gladioli, Iris, and an extensive stock of other roots.

Post-office Orders payable to **STEPHEN BROWN**, Seed and Horticultural Establishment, Sudbury, Suffolk.

HORTICULTURAL BUILDING AND HEATING BY HOT WATER.

Warranted best Materials and Workmanship, at the lowest possible prices.

J. WEEKS & Co., King's Road, Chelsea, Horticultural Architects, Hothouse Builders, and Hot-water Apparatus Manufacturers. The Nobility and Gentry about to erect Horticultural Buildings, or the Hot-water Apparatus, will find at our Hothouse Works, King's Road, Chelsea, an extensive

variety of Hothouses, Greenhouses, Conservatories, Pits, &c., erected, and in full operation, combining all modern improvements, so that a lady or gentleman can select the description of House best adapted for every required purpose. The Hot-water Apparatuses (which are efficient and economical), are particularly worthy of attention, and are erected in all the Houses, Pits, &c., for both Top and Bottom Heat, and in constant operation in the Stoves. The splendid collection of Stove and Greenhouse Plants are in the highest state of cultivation, and for sale at very low prices. Also, a fine collection of strong Grape Vines in pots from eyes, all the best sorts. Plans, Models, and Estimates of Horticultural Buildings; also, Catalogues of Plants, Vines, Seeds, &c., forwarded on application.

J. WEEKS & Co., King's Road, Chelsea, London.

TEAS ARE LOWER IN PRICE.—The Stock of Tea in England being nearly ten million pounds more than at this time last year, prices have, in consequence, given way, and enables us to sell really good Teas at very low prices.

The Congou Tea at 3s 4d per pound, and the Hyson Gunpowder at 4s per pound, make an excellent Mixture for general use, while the fine, rich Soucheong Tea at 4s, and the rare choice Gunpowder at 5s, are so really good and truly cheap, that we confidently recommend them to all who desire very superior tea.

We are also selling pure Jamaica Coffee at 1s per pound, and the best Mocha Coffee at 1s 4d. Tea or Coffee to the value of 40s sent carriage free to any part of England, by **PHILLIPS AND COMPANY**, Tea Merchants, 8, King William Street, City, London.

Prospectuses, with Drawings, forwarded free.

Plain, 12s to 25s. Ornamental, 31s 6d to £6 6s.
Stands for Stoves, 2s 6d, 3s, and 5s, each.

CAUTION.—An Injunction having been granted by the Vice Chancellor in the case of "NASH v. CARMAN," restraining the Defendant from making or selling any colourable imitations of the Plaintiff's Stove or Fuel, the Public is respectfully informed that the "JOYCE'S PATENT STOVE," "WITHOUT A FLUE," and the "PATENT PREPARED FUEL," can only be obtained from the Proprietor or his authorized Agents. Every genuine Stove has the Proprietor's name and address on a brass-plate on the front:—

"**SWAN NASH, 253, Oxford Street, London.**"

JOYCE'S PATENT, for warming Halls, Passages, Harness-rooms, Greenhouses, Water-closets, &c., &c. The above Stoves do not emit smoke or unpleasant smell, and will burn without attention or replenishing from 12 to 48 hours. In use daily at the Sole Proprietor's, **SWAN NASH'S**, Ironmonger, 253, Oxford Street, and at the Depot (City), 119, Newgate Street, London; and to be had from the principal Ironmongers in Town and Country.

PATENT PREPARED FUEL, 2s 6d per bushel, only genuine with the Proprietor's name and seal on the sack. **SWAN NASH, 253, Oxford Street, and 119, NEWGATE STREET.**

N.B.—Sole Maker of the **PORTABLE VAPOUR-BATH**, for Families and Travellers, &c., &c., as recommended by the Faculty, complete with large Cloak, £1 11s 6d. **SYPHON AIR-VENT BEER AND WINE TAPS**, 3s 6d; electro-silvered, 5s 6d.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last twenty-five years, the average highest and lowest temperatures of these days are 56.3° and 40.1° respectively. The greatest heat, 73°, occurred on the 21st in 1830; and the lowest cold, 20°, on the 21st in 1842. During the period 90 days were fine, and on 95 rain fell.

ROUGH-LEAVED COMMELIN.

(*Commelina scabra*.)

THIS is one of an old genus of herbaceous plants, natives of different countries, some of them requiring the heat

of a stove, others the shelter of a greenhouse, while a third section withstand the rigour of our winters. All of them have fleshy roots or rhizomes, and they belong to the natural order, Spiderworts, the genus *Tradescantia* being the next of the order which is best known to cultivators. They fill up a transition point between the sedges and sedge-like plants, as Xyrids, on the one hand, and the Lilyworts on the other. The genus was named in honour of J. and G. Commelin, two Dutch botanists, by Dillenius, a celebrated professor of botany at Oxford, after whom Linnæus named the genus *Dillenia*. The subject of this biography was introduced from Mexico by Mr. Allardt, of Berlin. It is a half-hardy perennial, and a good figure of it is given in *Paxton's Flower Garden*, iii. 8. *Stems* in a tuft, milky-green, tinged with red. *Leaves* stalkless, sheathing the stems, spear-head-shaped, stiff, horny at the edge, wavy, milky-green, covered with rough elevations. *Flower-sheath* heart-shaped, downy, enclosing from five to ten flowers. *Petals* dull purplish-brown. The genus is included in Triandria Monogynia, class and order of Linnæus. B. J.

Culture and Propagation.—These *Commelinas* are not much in favour among gardeners of the present day, but I recollect the time when as much care was taken of them as is now given to the Dahlias. As soon as the frost cut down the stems, we housed the roots, which grow after the manner of Asparagus, along with those of the Marvel of Peru, Dahlias, Carrots, Parsnips, and Beet-root, in dry sand, away from the frost. In the spring, say in April, they were replanted in light, rich earth in the mixed borders, and if we wanted to increase them, that was effected by dividing the roots as you would a Dahlia, taking an eye or eyes along with each portion of roots. D. BEATON.

A CORRESPONDENT asks us whether we think "the Black Violets (*Nigræ violæ*.—Eclogue, x. 39), the Soft Violet (*Viola mollis*.—Eclogue, v. 38), and the Pale Violets (*Violas pallentes*.—Eclogue, ii. 47), mentioned by Virgil, refer exclusively to our Common Violet?" Without entering into any classical disquisition, or quoting parallel passages from Pliny, Horace, Columella, &c., we reply generally that we believe the references are to one and the same flower, and that that flower is our Common Sweet-scented Violet (*Viola odorata*). "Dark" is quite as faithful a translation of *niger* as "black;" when the Violet is spoken of as "soft," it is in contrast to the thistle, and other armed plants; and the Pale Violets are quite in unison with our White variety. The same correspondent asks if "our Double Violets are recent results of our floricultural skill?" and we will give a reply in the words of old Gerarde, who wrote in 1597—"The Double Garden Violet hath leaves, creeping branches and roots, like the Garden Single Violet; differing in that this sort bringeth forth most beautiful sweet double flowers.—Violets called the Black or Purple Violets, or March Violets of the garden, have a

great prerogative above others, not only because the mind conceiveth a certain pleasure and recreation by smelling and handling of those most odoriferous flowers, but also for that very many by these Violets receive ornament and comely grace; for there be made of them garlands for the head, nosegays, and poesies, which are delightful to look on and pleasant to smell to, speaking nothing of their appropriate virtues; yea, gardens themselves receive by these the greatest ornament of all, chiefest beauty, and most gallant grace; and the recreation of the mind which is taken thereby cannot but be very good and honest: for they admonish and stir up a man to that which is comely and honest; for flowers, through their beauty, variety of colour, and exquisite form, do bring to a liberal and gentle manly mind the remembrance of honesty, comeliness, and all kinds of virtues. It would be an unseemly and filthy thing (as a certain wise man hath said) for him that doth look upon and handle fair and beautiful things, and who frequenteth in fair and beautiful places, to have his mind not fair, but filthy and deformed." Gerarde was a sober and ancient herbalist when he thus wrote, and

we might readily believe, even did we not know the flower, that the Violet must have extraordinary charms, when it could thus excite sedateness to be eloquent.

We shall have occasion to dwell more fully upon the admitted virtues of the Violet when we come to it in due course among the "British Wild Flowers," but we must extract here one note from Willsford's "Secrets of Nature," which says, "When *Violets* flourish in autumn, it is an evil sign of an insuing plague the year following, or some pestiferous disease." If this be so, then will 1853 be a year memorable for its pestilence, for we have before us, October 12th, bouquets and growing plants of the most highly-scented and largest *Violets* we have ever looked upon. These are Shackell's *Russian Superb Violets*; they are treble the size, and far more fragrant than the common Russian Violet similarly cultivated, and though their leaves are also very large, yet the stalks of the flowers are so long and stout, as to render them very conspicuous. Mr. Shackell has a large stock of every description of *Violets*, and intends to sell them at such low prices as to be within the command of all classes. He will, before long, publicly announce his charges. Even Tree *Violets* will be sold very cheap.

FORSYTH MSS.

At page 185 of our 5th volume we gave a biographical sketch of SIR JAMES EDWARD SMITH, the first President of the Linnæan Society, and author of *The English Flora*, and other standard works. The following letter is dated Norwich, September 25th, 1802.

SIR J. E. SMITH TO MR. FORSYTH.

No cause less powerful than the real one should have kept me so long without thanking you for your kind and valuable present of your work, which I now most heartily do. When I received it, I was just beginning to be ill with a fever of violent erysipelas, which detained me a fortnight at Hendon; and then, after my journey home, I was for many weeks unable to look at anything, and in great pain. My complaint is not yet quite gone, but I begin to use my eyes moderately. Your book is in great request here, as it deserves. Mr. Crowe has one copy for his gardener, another for himself, as he makes it his constant study. I have no doubt the general practice of your directions about trees will be of the greatest public use and benefit.

Mr. Crowe and I have again this year been hard at work upon British Willows. Our certain species are about forty. Would it be interesting to you to have cuttings sent you in the winter of all our species, marked with my names? I should be very glad of this, or any other opportunity, of shewing you how much I am, dear Sir, your obliged and faithful friend,

J. E. SMITH.

It may be as well to explain to the non-botanical reader, that the genus *Salix* includes the British Willows, and, in all, about two-hundred-and-twenty-two species, varying in locality from the *Salix arctica*, the last woody plant that lingers in existence as we approach the north pole, to the *Salix Babylonica*, which is found not only "by the waters of Babylon," but in China, Japan, and Northern Africa. These numerous species have been, and still are, the opprobrium of botanists. No one laboured more successfully to arrange them than did Sir J. E. Smith, and his friend Mr. Crowe, until since his death, M. Koch, a German botanist, has

bestowed upon them an amount of knowledge and deep investigation which has left little to be desired.

COVENT GARDEN.

How deep-seated evil practices become! It is upwards of a hundred years since an old writer cautioned the public of that day against the sellers of *Elder berries* and *Elder juice* in Covent-Garden; and it is sad that we should have occasion to do the same now. For a week or two past these commodities have been exposed for sale in considerable quantities. Of the former we need make no remarks, as it is hardly possible that any one could be led astray in the choice of berries, provided they made use of common observation; but against what is sold as *Elder juice* we would have them be especially careful. This article is generally exposed in tubs, and mixed with a large proportion of berries and stalks; but even to a casual observer, the berries show no proportion to the liquor, a great part of which is, in fact, water. "Thus," says the writer above alluded to, "wines and syrups made from *Elder berries* may prove defective, and discourage persons from making a second attempt, by the measure of water with the *Elder juice*, or from blighting causes, or its being expressed from unripe berries." We have thought it our duty to put our readers on their guard against such practices, and would recommend them in all cases, when *Elder wine* is the ultimatum, to provide themselves with sound and well-ripened berries only.

In the fruit-market the supplies have been large during the past week, and the demand little short of what we reported in our last. Everything maintained fully as good prices, and there is every probability they will continue to do so. *APPLES*, it is generally believed, are a short crop throughout those parts from which "The Garden" supply is generally derived, and I am aware of some cases where salesmen have advised their employers to hold, as there is every probability there will be a considerable rise as the season advances. The varieties which have been most plentiful during the week, besides those which we have noticed in former reports, are *Beauty of Kent*—a beauty, indeed, but this season they are very much deformed, having almost entirely lost their conical shape, and become somewhat flattened and angular; they still, however, retain their beauty of colouring and russety base. This must not be confused with the *Flower of Kent*, under which name it is often met with in the market. Though both are good apples, still the former is by far the better one of the two. It is one of the most magnificent apples we know, when grown to perfection, and is one of the best autumn baking varieties. *Emperor Alexander*, of which we made mention last week, is in still. It is like a great many more things in the world, more for show than for use; and I would, therefore, never recommend any one who has only a limited extent of ground to think of growing it. *PEARS* are plentiful, and of all qualities, many of them being, as the costermongers call them, "fine mellow pears." However these may have

done a hundred years ago, they will not do now by the side of *Beurre Bose*, *Duchesse d'Angoulême*, and *Jersey Gratioli*, all of which are now to be had in quantity. The latter is a most delicious, rich, and sprightly flavoured fruit. It possesses that peculiar briskness which is only to be found in a pine-apple, and which one is loathe to call acid; and at the same time is rich and sugary. This is a variety which can be "highly recommended," and which ought certainly to find a place in every garden. PLUMS are going out, and we have nothing new to notice besides what we have treated of in former reports; there are still, however, some arrivals of foreign baking varieties, of what the Germans call *Quetsche* family. The GRAPES continue the same as last week, being chiefly *Black Hamburgs* and *Cannon Hall Muscats*. There has been a large arrival during the week of foreign Black Hamburgs in baskets, in excellent condition, which fetched from 1s. to 1s. 3d. per lb. There are still some late PEACHES to be met with in the first-class fruiterers', but the few remaining NECTARINES there are do not seem very tempting. PINES are plentiful for the demand, and make from 3s. 6d. to 6s. per lb.

In the vegetable department there has been a plentiful supply. CABBAGES make from 6s. to 7s. per dozen, according to the size and quality. The variety which is most extensively grown for the London markets is the *Battersea*, which is also known in the country by many names, such as "Fulham," "Barnes," "Emperor," and "London Market." CAULIFLOWERS are excellent, and vary in price from 1s. to 2s. 6d. per dozen. BRUSSELS SPROUTS have come in, and are to be had at from 1s. 6d. to 2s. per half-sieve. FRENCH BEANS are less plentiful, and are, consequently, making more money. Some weeks ago they could not be sold at any price, but now they are making from 2s. to 2s. 6d. CELERY is very fine; the best can be had at 1s. 3d. per bundle. TURNIPS from 2s. to 2s. 6d. per dozen bunches; and CARROTS 2s. 6d. to 4s. per dozen bunches. POTATOES are on the rise, and likely to continue so; they make from £3 to £6 per ton; the finest are the *Regents*, which are in excellent condition, and make from 3s. 6d. to 4s. per bushel. MUSHROOMS still continue plentiful, at last week's quotations. H.

GOSSIP.

AMONG the very numerous charities at Winchester is *The Natives' Society*, for the apprenticing of the children of poor citizens. It was founded in 1669, but we only notice it for the purpose of quoting some of the prices paid for articles connected with the Society's annual festival in the days of yore.

"1675.—Paid for 9 bushells of malt and grinding £1 6 0
Paid for halfe a bushell of barley for the
poultry - - - - - 0 1 0
"1676.—For lemonds, 4d. For aples, 2s. For cabidge and
cariot, 1s. 6d. For 4 bushells of wheat, 12s. 6d."

At the *Yarmouth Poultry Show*, Miss E. Watts took a first prize for dark-coloured Cochinchina Chickens, and not a second prize, as stated in p. 418 of our last volume.

There is a brilliancy—a glory—around the fall of the warrior on the field of victory that takes away much from the mournfulness of death. We think we are not wrong in saying that there are few so base as to shrink from facing that death with a firm onward foot, and an unquailing heart, amid the ranks of comrades, and all the excitement and panoply of war. This is courage; but it is courage which excitement would infuse into a poltroon. There is another courage which we consider more admirable, though less appreciated—we mean that of the dying student, who, suffering under the slow inroads of an incurable disease, still labours on in the quiet retirement of his library, intent to fulfil his allotted task, though well assured that death's foot is far advanced across his threshold. This is passive courage—this is genuine heroism—and never was it more forcibly displayed than by DR. WILLIAM MACGILLIVRAY, late Professor of Natural Philosophy in the University of Aberdeen. The two concluding volumes of his *History of British Birds* have just been published, and these are the contents of their concluding page:—

"Commenced in hope, and carried on with zeal, though ended in sorrow and sickness, I can look upon my work without much regard to the opinions which contemporary writers may form of it, assured that what is useful in it will not be forgotten, and knowing that already it has had a beneficial effect on many of the present, and will more powerfully influence the next generation of our home-ornithologists. I had been led to think that I had occasionally been somewhat rude, or at least blunt, in my criticisms; but I do not perceive wherein I have much erred in that respect, and I feel no inclination to apologise. I have been honest and sincere in my endeavours to promote the truth. With death, apparently not distant, before my eyes, I am pleased to think that I have not countenanced error, through fear of favour. Neither have I in any case modified my sentiments so as to endeavour thereby to conceal or palliate my faults. Though I might have accomplished more, I am thankful for having been permitted to add very considerably to the knowledge previously obtained of a very pleasant subject. If I have not very frequently indulged in reflections on the power, wisdom, and goodness of God, as suggested by even my imperfect understanding of His wonderful works, it is not because I have not ever been sensible of the relation between the Creator and His creatures, nor because my chief enjoyment when wandering among the hills and valleys, exploring the rugged shores of the ocean, or searching the cultivated fields, has not been in the sense of His presence. "To Him who alone doeth great wonders," be all glory and praise. Reader, farewell."

Death, indeed, was "not distant" when Doctor Macgillivray penned those thoughts on the last day of July, for in little more than six weeks he was within his grave. The opinion he had of the work of his dying years, for it occupied twelve, was not too high. We have perused it thoroughly, and we rose from it with the conviction that it is the best work existing on British Ornithology. It is the best for all the reasons that render such a book valuable—for its descriptions are most full and most accurate—its anatomical demonstrations more perfect than any previously effected—and the habits, haunts, and associations of each bird are most pleasingly described, not only with all the freshness induced by personal examination, but with all the spirit of a genuine lover of nature. We have room only for this short description of the habits of the *Red-breasted Goosander*:—

"In the outer Hebrides, in March, April, and part of

May, and again in autumn, I have seen very large flocks in the small sandy bays, fishing day after day for sand-eels. They sit in the water much in the manner of the Cormorants, but without sinking so deep, unless when alarmed, and advance with great speed. It is a pleasant occupation to an idle scholar or wandering ornithologist to watch one of these flocks as it sweeps along the shores. I have many times engaged in it, both with the desire of shooting some of them, and of studying their manners, which are very graceful. You may suppose us to be jammed into the crack of a rock, with our hats off, and we peeping cunningly at the advanced guard of the squadron, which is rounding the point at no great distance. There they glide along, and now, coming into shallow water, they poke their heads into it, raise them, and seem to look around, lest some masked battery should open upon them unawares. Now one has plunged with a jerk, another, one here, one there, at length the whole flock. Now start up, and if you wish a shot, run to the water's edge, and get down among the sea-weed behind a stone, while I from this eminence survey the submerged flock. How smartly they shoot along under the water, with partially outspread wings, some darting right forward, others wheeling or winding, most of them close to the sandy bottom, but a few near the surface. Some flounders, startled by the hurricane, shoot right out to sea, without being pursued. But there, one is up, another, and I must sink to repose in some hole. How prettily they rise to the surface, one here, another there, a whole covey at once emerging, and all without the least noise or splutter. But they are far beyond shot range. However, having come near the next rocky point, they now turn, dive in succession, and will scour the little bay until arising here at hand they will be liable to receive a salute that will astonish them. A whole minute has elapsed, half another; but now one appears, two, many, the whole flock; and into the midst of them pours the duck-shot, while the noise of the explosion seems to roll along the hill-side. In a twinkling all are down, save six that float on the water, four dead, one spinning round, and the other striving in vain to dive. In less than two minutes they are seen emerging, more than a quarter of a mile out at sea, and presently again they are out of sight. On such occasions they seldom fly."

A correspondent writing to us from Inverness, says:—

"An immense breadth of *Potatoes* is planted here, (chiefly Irish cups); about one-half of the produce is destroyed by the disease, and it is astonishing to me with what cool indifference her Majesty's subjects allow them to remain in the ground to rot! For the life of me I cannot understand this apathy for the potatoes.

"The harvest is completed in first-rate order, and the produce generally abundant. The *Turnip* crops are splendid, with very few exceptions, and some mildew.

"What capital farming, generally speaking, we meet with in Scotland; I admire the quiet method of their proceedings, but the women are worked too hard."

We hear that the first-class collection of *Cochin-China* fowls formed by Mr. Andrews, of Dorchester, have been sold by him to Mr. Cattlin, of London, for £250. We hope Mr. Andrews will address himself to raising a fresh yard of them.

The *Cornwall Society's Exhibition of Poultry*, as stated in our advertisement columns, is fixed for the 10th and 11th of January, 1853. Its premiums, considering that it must, from difficulty of access, be comparatively local, are liberal, and its rules good—so good, that several of them have been adopted by the Winchester and Southern Counties Society for the improvement of Poultry. We have no doubt as to the show being good, for the published accounts of the poultry-yards near Penzance shew that they have first-rate birds in its vicinity. We hope soon to publish extracts from those accounts.

The following is a list of the *Horticultural and Poultry Shows* of which we are at present aware. We shall be obliged by any of our readers sending us additions to the list, and giving the address of the Secretaries.

HORTICULTURAL SHOWS.

- BURY ST. EDMUNDS, Nov. 26 (Chrysanthemums). (*Sec.* G. P. Clay, Esq.)
 CALEDONIAN (Inverleith Row), Edinburgh, Dec. 2.
 HAMPSHIRE, Nov. 18 (Winchester). (*Sec.* Rev. F. Wickham, Winchester.)
 LONDON FLORICULTURAL (Exeter Hall, Strand), Nov. 9+, 23, Dec. 14+.
 NORTH LONDON, Nov. 23, Chrysanthemum.
 SOUTH LONDON (ROYAL), Nov. 11+, Dec. 9+, 16.

POULTRY SHOWS.

- BIRMINGHAM AND MIDLAND COUNTIES, 14th, 15th, 16th, and 17th December.
 BRISTOL AGRICULTURAL, December 7th, 8th, and 9th. (*Sec.* James Marmont.)
 CORNWALL (PENZANCE), January 10th, and 11th. (*Secs.* Rev. W. W. Wingfield, Gulval Vicarage, and E. H. Rodd, Esq.)
 DORCHESTER, Nov. 18th. (*Sec.*, G. J. Andrews, Esq., Dorchester.)

† For seedlings only.

FRUIT STORES.

WE must break in on the series of Pine papers for a week, in order to offer advice on this head. As to gathering, of course much of that will have been performed. The gathering, however, is pretty well understood; and the amount of care requisite tolerably well appreciated. Some of our late pears will be still out in places, such as the Winter Neils, the Glout Morceau, Beurré d'Arenberg, Beurré Rance, Ne plus Meuris, and some of Mr. Rivers's new continental kinds, of which, as far as tried, we cannot speak very highly in the north; in the southern portions of the kingdom they may deserve a very high character. We are no advocates for letting the fruit remain long enough on the trees to endure several degrees of frost. A thermometer of 28° may, perhaps, do no harm, but lower we would never go if we could avoid it. Indeed, after the first week of October, it is probable fruits receive but little benefit from the tree: that they may receive harm is certain. The juices of the tree become very sluggish after that period, and the elaborative functions of the foliage almost a nominal affair, as far as the fruit is concerned, and this more especially with regard to fruits from warmer climates. And now a few words as to the keeping of our valuable winter apples and pears, about which some difference of opinion still exists. It is evident that the main principles we have to consider in this question are as follows—

The temperature.

The hygrometric conditions.

The action of the atmosphere.

Beyond this, we think nothing of any weight pertains to the question; whether they lie on straw, fern, or paper, or on the mere boards, or on any other material, matters little, only as far as they contribute to the carrying-out the necessary conditions, or of saving the fruit from bruises.

As to temperature, there is little doubt that coolness, or that amount of cold which would be unpleasant to endure sitting in a room, is absolutely essential to the long keeping of fruits. But whilst this is observed, let it not be supposed that a single degree of frost may be permitted. Whatever injury it may do the fruit whilst in a growing state on the tree, there is little doubt that much more injury accrues from such conditions when in a transition state from firmness to mellowness.

Some very peculiar changes of a chemical character are well-known to be requisite, and to take place, unless arrested during the ripening process; the chief arrest being, we imagine, occasioned by sudden and injurious depressions of temperature. Some of our best pears will become, under such circumstances, like petrifications, and totally insipid. What has been termed "bletting," that is a sweet-tasted decay, as in the *Medlar*, is probably thus caused, and, indeed, other evils; this at once points to the propriety of being enabled to remove them, when necessary, to a room where a temperature of 50° to 60° can be sustained at any time. Now, we should scarcely think it necessary to fix a heating apparatus in the general store-room; there should be a special room for this purpose in all gardens of any consideration. The grudging little outlays for this purpose belongs, we would hope, to bygone days; for the apothegm "what is worth doing, is worth doing well," gathers strength every day, and has long since invaded the precincts of the garden. In planning new fruit-rooms, we would, from a door at one end of the store-room, enter a little snug box, having a heating apparatus of hot water, the boiler outside, and the interior fitted with a few shelves on one side, and a few receptacles, or nests for shelves, on the other, with a small bench for operations. These shelves would be useful in containing those fruits which, at all periods require a higher temperature, as, indeed, all fruits for immediate consumption would do unless quite ripe. The nests, or receptacles, should be a counterpart of a similar set in the general store-room; and these two rooms would have to exchange fruits very frequently: those ripe and to be retarded moved from the warm room to the cold one, and *vice versâ*. We are here, as in duty bound, setting forth a somewhat high course of practice; not high through complicated machinery or mighty expense, but involving a little trouble, attention—perseverance, if you will. Those who can afford to do such things, and who turn back in dread, we must pass by for the present. It is no part of the duties of those who attempt to advise in these times to affect a very low standard, carrying a specious appearance of economy outside, but penny wise and pound foolish within. We are aware that not all small gardeners can do these things; still it is well to lead even these to a consideration of principles, and of the ultimatum to which everything in the present condition of society has a tendency.

To resume, then, the course of the subject; having spoken of the warm or ripening room, let us think of the character of the general store-room. This, of course, should be much more capacious; whatever the size of the establishment, we should say as six to two. Here would be permanent shelves for those ordinary kitchen apples, common pears, &c., which, once housed, would not require to be removed. On the other hand, there might be sets of drawers, or trays, of a moveable character, exactly fitting the set of nests or receptacles before described in the warm room, so that one or more might be moved at any time with facility. Thus, then, to put a case: we will say this October the 4th we want to retard some *Delice d'Hardenpont* pears, and to hasten some *Marie Louise*; we will then take No. 1 in the warm room, containing the *Delice*, to No. 1 in cool room, containing some *Marie Louise*, and "ring the changes." Again, No. 15 in warm room is a tray of greengages from a north wall, now perfectly mellow; they must be "cooled down." Let us exchange them for No. 8 tray in the cool room, which contains *Ribston Pippins*, and which will be required in a mellow state for some large parties, who are pheasant shooting in the middle of the month. As before observed, these trays must be made to fit the respective nests with ease; this done, the transit is accomplished without the least detriment to the fruit.

About the modes of heating, &c., we have not space for an observation; such may stand over to the long winter evenings, which approach with giant strides.

We pass on to the hygrometric conditions, our second postulate; the amount of moisture permissible or desirable in the air of the fruit-room. This is a somewhat puzzling part of the question, inasmuch as authorities of high standing, and too respectable to be totally set aside, may be found, who throw their bias sometimes into one scale, sometimes into the other. There can be little doubt, we think, that the epidermis (skin) in fruits acts by transpiration, and that such transpirations is, in a degree, arrested by a somewhat damp condition of air; albeit, as we think, at the expense of flavour and mellowness in fruits. However, in this matter, we ought to distinguish carefully; to keep late apples from shrivelling, and to preserve such things as delicate-skinned pears, plums, melons, cherries, &c., are two very different affairs.

With regard to the varying conditions necessary, and the crisis which occurs from the gathering of the fruit to its consumption, much may be said. Mr. Knight, of Downton, made the following remarks:—"Fruits which have been grown on standard trees in climates sufficiently warm and favourable to bring them to maturity, are generally more firm in their texture and more saccharine, and, therefore, more capable of being long preserved sound than such as have been produced by wall trees; and a dry and warm atmosphere also operates very favourably to the preservation of fruits under certain circumstances, but, under other circumstances, very injuriously; for the action of those elective attractions which occasion the decay and decomposition of fruits, is suspended by the operation of different causes in different fruits, and even in the same fruit in different states of maturity. When a grape is growing upon the vine, and until it has attained perfect maturity, it is obviously a living body, and its preservation is dependent upon the powers of life; but when the same fruit is sometimes past its state of perfect maturity, and has begun to shrivel, the powers of life are no longer, or, at most, very feeble in action, and the fruit appears then to be preserved by the combined operation of its cellular texture, the antiseptic powers of the saccharine substances it contains, and by the exclusion of air by the external skin, for if that be destroyed it immediately perishes. If longer retained in a dry and warm temperature, the grape becomes gradually converted into a raisin, and its component parts are then only held in combination by the ordinary laws of chemistry." Thus far Mr. Knight, whose observations went as far in these matters as any man, backed, at the same time, by the most extensive amount of physical knowledge. Now, we have capital illustrations of the soundness of at least one part of Mr. Knight's theory, especially in the *Marie Louise* pear. This we have growing in all forms—on table trellises, the ordinary espalier, the pyramid, and on east and west aspects, and a noble crop we have. Those on a west aspect have a skin like wax-work; those on the pyramid or table trellis, and exposed to every blast, have a russet coating; and those on the east aspect, about intermediate. Now, this has been the case for several years; every year has produced the same results. And what as to flavour and keeping properties? Why, as might be fairly anticipated, just corresponding with the character of the coating, or nearly so. To be nice over such points, however, there is a very peculiar difference between them on the palate, and, for our own part, we can scarcely tell which to covet; our worthy employer, however, who is as keen a judge as most gentlemen, and has a most extensive knowledge of fruits, seems always to prefer those with waxy skin, from the western aspects; and, indeed, they are larger, perhaps more melting, finer in texture, but

assuredly a lighter flavour, though excellent; but to be fair, those from the standards in our north latitude have a kind of snatch of the wildings in them, which, to some palates, is not disagreeable.

It is to be feared that these observations will appear too digressive, and we must hasten back to the main features of our tale. There can be little doubt that apples, especially the ordinary kitchen kinds, endure and enjoy a greater amount of danger than pears, or, indeed, any thin-skinned fruits. They have been well-preserved in ordinary cellars, nay, in pits, or "hogs," and, indeed, much beyond their ordinary season by such means, but, as before observed, at the expense of flavour. This is, however, another argument for the necessity of two rooms. If we must be compelled to keep a general store of all kinds together, we should prefer a room on the north side of an existing building, the floor about a foot above the ordinary ground level, and the exterior walls double, possessing a cavity of about six or eight inches all round the exterior. In the roof, we would have escapements for damp, to be opened at pleasure, and capable of graduation; and we would have similar openings in front, at two levels—one portion just above the floor, and the other near the top of the room. The admission of light need not be the means of ventilation; windows must be, of course, provided, in order to facilitate, when necessary, any arrangements connected with the fruit. This, however, is but a "lumping" of matters; whilst we write thus, we are perfectly assured that some fruits are the better for a moderate amount of moisture in the air; others the worse; and, as Mr. Knight observed, the same fruit at different periods requires varying conditions, in order to bring out its qualities in the highest perfection.

Want of space prevents our pursuing this interesting disquisition as far as existing facts would warrant, and we must pass on to consider

The Action of the Atmosphere.—We are afraid that in discussing this portion of the question little heed will be paid by some to its importance. There can be little doubt, however, that it is a question worthy of much consideration. As for the first gathering of the fruit, within a couple of weeks after which the fruit undergoes what is termed sweating, a most liberal ventilation is necessary to ordinary fruit. Here, again, the propriety of having two rooms irresistibly forces itself on our notice. But these things accomplished, a moderate course becomes necessary; and, indeed, towards Christmas, rooms in general require to be hermetically sealed, as it were. That the more rapid the current of air that passes over them, the greater the detraction of juices from the skin of the fruit, there can be no doubt; but this would seem to be, in some cases, necessary to produce flavour. However, any stagnation arising from moisture in excess must be dissipated by such means, or by heat; and, as before observed, we would have the ordinary stores kept in a cool condition. Whilst, therefore, the warm room would seldom require much air, the cool or store-room would require at times a liberal amount; all this determinable principally, if not entirely, by the character of the air within as to its amount of moisture.

Light.—This, although not placed amongst the conditions for consideration, is a most important affair; in former days paid little attention to. Now, however, the importance of darkness to fruit is almost universally recognised; and most practical men keep their fruit-room shutters closed. This it was that made us suggest ventilation by other means than the windows, for cases frequently occur when a circulation of air without light is essential. Every body knows that fruit is liable to acquire a tendency to breed those obscure cryptogamic bodies commonly termed "moulds," and that these, however induced, are increased by a damp air, and by light.

These are frequently induced by bruises; but some kinds of fruit show an evident predisposition to the produce of this pest. We have reason to believe that darkness is unfavourable to its spreading, and, if so, is another reason for keeping closed shutters. Although the patience of our readers may be exhausted by so much about fruit-keeping, yet we will not confess to the subject itself being exhausted; enough, however, has been said to set our readers thinking for themselves.

R. ERRINGTON.

SENDING PLANTS TO AUSTRALIA AND ELSEWHERE.

This subject occupied nearly as much of our attention for the last two years, as that about bees and poultry; and no doubt, when the flush of the diggings is over, and people there return to their senses, their cottages, and cottage gardens, we shall have an extended sale for our publication in those quarters, and a new impulse will arise in the trade in plants between the two countries. Until the Isthmus of Panama is smoothed down for steam carriage, it is still the safest way to send plants round Cape Horn for the different ports in Chili and Peru, and the trade from London to those ports, as I shall presently show, is reported from the nurseries, and the last accounts from the Cape of Good Hope bring whisperings of gold stores, where the old Caffir Chiefs will one day or other join issue with General Cathcart himself, and his "burgher levies," in a different game, after casting their swords and spears into the Fish River. Here, then, is another opening, in anticipation, for our nurseries and emigration societies to pour in their accumulated stores, to say nothing of the Indian and China market, upon all of which it is better to keep our eye than to sleep with one eye open. I was at Oxford the other day, where I made a whole budget of university, or rather universal, news about gardening; and having, by mere chance, got into conversation with patrons of THE COTTAGE GARDENER, who were discussing the merits of the different ways of transmitting plants to distant parts, I learned that Mr. Low, of the Clapton Nursery, was in the constant habit of executing orders for Australia, New Zealand, and South America; but to make sure of the point, I returned to London the same evening, all in the dark, for the people of the "Great Western" do not provide lights for their second-class passengers like the South Western Company, in whose carriages you could read the small print edition of Uncle Tom's Cabin any night in the week. I was in Clapton just in time to see a large case of plants packed for New Zealand, and another one in progress for Valparaiso. I also saw two more orders, one for Brazil and another for the West Indies. The latter is to be sent out on Ward's plan, and the case is to be returned with bread-fruit trees and others that are scarce in the trade. What was better than all, the packer is an old play-fellow of mine, Mr. McDonald, a well-known gardener of great experience and skill; and, as a matter of course, he made no secret of his way of packing, which is so sure and effectual, that large orders are sent to Mr. Low from the most distant parts, through no other interest than the celebrity of his packers. Indeed, a letter was pointed out to me in proof of this, from the same British resident in Valparaiso to whom the present consignment is to be sent, in which he states that the last plants he had from Clapton arrived in as good health as when they left Clapton, and that some of the Rhododendrons and Camellias were in full blossom when he unpacked them.

From the end of September to about Christmas, Mr. Low thinks is the best time to pack plants for such long journeys; but he has packed in all seasons. The case

that I saw packed for New Zealand is going out with a reverend gentleman (Mr. Baily), who is going on a visit to Taranaki. It was four feet six inches long, nearly two feet deep, and as much in width, of strong one-inch deal; one-half of the plants were packed with the roots in the packing materials, placed against one end of the case, the other half at the other end, and thus their heads met in the middle of the case free from any packing-stuff. I was told that a few holes were to be made on either side of the case in the middle, to let off any damp or vapour from the leaves or packing stuff, but not so large as to admit a mouse. The whole was nailed down firmly, the case then strongly corded, and the address was painted on the lid; and, as an additional strength, strips of half-inch board were nailed all round the case in the middle, and also at both ends, the cords running close to these strips, so that they could hardly be "chaffed," or worn by the tossings of the vessel in bad weather. The plants were of a mixed character, twenty-four of them being shrubs or trees, and a dozen Pinuses, and other things of which I did not think it worth while to take the names, as none of us know really what is most in demand either in New Zealand or Australia; but I expect soon to get a sight of a very long and interesting letter, written from Australia, in which a great many things are explained respecting the gardening want of the different settlements, as well as the gardening gossip of the day in these parts. This is just what every one that is interested in the subject wants to know.

I copied the following digest from the invoice going out to Valparaiso:—450 *Camellias*, 100 of which to be the old double white; 240 maiden plants of twelve kinds of *Plums*; 25 *Ribes sanguineum*; 12 of the *White Ribes*, a variety of *Sanguineum*; 100 newest *Dahlias*; 6 *Stanwick Nectarines*, and 50 *Daphne indica rubra*, together with a host of single plants, many of which, I could vouch for it, were culled from the pages of THE COTTAGE GARDENER. Our friends in South America thus seem to have as much confidence in our recommendations as their brethren in the United States, who, as Mr. Brint, of Philadelphia, told me last July, have the fullest confidence in whatever appears in our pages about new plants. How lenient, therefore, ought our home correspondents to treat our hesitations about getting up lists of such-and-such plants on the spur of the moment, when we have such a weight of responsibility, that ought to be most conscientiously discharged for the good of all parties.

The principle of the mode of packing adopted in this nursery is that which I have all along recommended, but the application of it is different. First of all, the plants are well watered, so as to have every part of the balls wetted through and through; they are then put aside to allow sufficient time for draining off the superfluous moisture. Meantime, a quantity of moss from Epping Forest is thus prepared:—Take a large tub, and pour a potful of water into it, then put in as much of good sandy loam as will form the whole into a thick puddle, or paint; now throw in a quantity of moss, and work it with the puddle, taking care to have every particle of the moss smeared with the compost; with this daubed moss cover each bulb half-an-inch thick, and fasten it round with strings of fresh matting, or small twine. When the whole are thus finished, begin to pack, by placing an inch of perfectly dry moss on the bottom of the case, at one end; on this place a row of the balls on their sides, with the bottom of the balls facing the end of the case, with another inch of dry moss intervening between the balls and that end. The balls being round, there will be little empty spaces between them at top and bottom; these spaces must be filled up with more daubed moss. We have now one layer of plants with their heads lying towards the

middle of the case, a bed of dry moss under and behind the balls, but nothing yet in front of the balls, or what was the surface of the pots. Along this front a layer of the dry moss, two inches thick, is very closely packed, and a piece of stout deal, or board, the exact size of the width of the case, is placed closely against this layer, and nailed at both ends from the outside of the case; the next layer of plants is then packed over the first, and pressed down so as to get bedded in the puddled moss, dry moss being placed all round, as with the first layer, and the interstices filled up with the puddled moss; another bar across as before, and so on till that end is filled, finishing with a layer of dry moss, on which the lid rests. Then finish the other end of the box, or case, just in the same way, and when the lid is nailed on let us turn up the case on one end, and see how the whole stands with the mind's eye. The whole mass in the centre, within the dry moss, is in that state we call neither wet nor dry, and so close throughout that no breath of air can get into it. This of itself, in a wooden box, would remain a long time sufficiently damp to keep the plants alive in their dormant state; but see how things would turn as soon as the vessel got within the tropics—even if there was no jolting of the vessel all the time to disturb the puddle, the wood would not be proof altogether against the heat of a vertical sun, and the damp of the moss would, in time, rise in vapour, and smother the leaves, rot the young shoots, and probably destroy every plant long before they reached the latitude of the Cape of Good Hope; but the firm lining of dry moss—and it must be very firm indeed, and so must the whole mass—is found in practice to be quite proof against any dispersion of damp or vapour whatever, as well as being one of the best non-conductors of heat; and, like the proof of the pudding, all this has been proved in a hundred instances, over a great many years, and to all parts of the globe. I dare say Mr. Low, Mr. Veitch, and all the nurserymen who import plants largely from distant parts, could tell of the hundreds of pounds that have been utterly lost to them from bad packing; and no doubt this system has been arrived at bit-by-bit, although they do not like now to rake up these unpleasant recollections, to which I could myself add a mite or two as big as a locust, if it were to any good purpose; so that my hasty return from Oxford, *all in the dark*, to learn a better system, may be the more easily accounted for, although I must go back, *some day* or other, to finish my notes on the interesting things I left unnoticed this time.

As far as I could make out from the explanation of Mr. McDonald, the great packer, loam is better for puddle than clay, as if it should get too dry, it does not bind so hard as clay would do to injure the roots; mixing it with moss gives a double chance, or rather three chances to one in our favour, for it keeps the whole open, as it were, for the roots to work into the puddle, should they be excited in running through the hot part of the journey, and all gardeners know that roots will run along vigorously on the least application of heat, although the branches be leafless, and encrusted in frost or snow:—make a hot-bed over the roots of any of our hardy trees next winter, and prove the fact, if you doubt this. Indeed, although I cannot explain my meaning so as to make it as clear as I should wish it to be, I am almost sure that the turning point in this safe way of packing, is in allowing the roots to extend freely under high pressure, so to speak:—we have all of us seen trees that have been felled in February brought into full leaf by a few April showers, and that accounts for the effect of the small holes in the sides of the packing case, letting off the vapour that might endanger the heads of the confined plants on this voyage. But there is another turning point. As soon as the heat converts

the dampness of this puddle into vapour, the moss in it sucks it up like a sponge, and on getting into cooler quarters, the loam sucks it back from the moss, and so by a system of "give and take," the moisture is retained in the moss for a very long time, much longer than could be expected from either the moss or the loam by itself; at any rate, the effects are now fully known and taken advantage of, whether we can explain them properly or not.

One remark which Mr. McDonald made to me I cannot withhold, as it may be of use in extreme cases. He said that, if this box was placed inside another box that was one inch larger all round, and that inch space filled with charcoal dust, the whole might go to Taranaki and back again with perfect safety to the plants. I also learned that a hundred plants, including fruit-trees, might thus be packed, and sent on board in London, at from 1s. to 1s. 6d. per head.

D. BEATON.

NOTES ON WINDOW-GARDENING.

WITH all the deficiencies that exist in this department, there are great and pleasing signs of progress. Often have I witnessed results that would constitute no inappropriate lesson to the best gardeners among us. These happy effects are never the consequence of what the indolent too often term "a lucky hit," or "a lucky chance." I have no faith in such chances. I look upon the expression, "lucky fellow," as one which ignorance too often trippingly uses for shrouding from itself its own thriftlessness, idleness, and impudence. From the window of the lady's buodoir, to that in the garret of the street apple woman; from the balcony in a suburban retreat, to the smoky leads on the summits of houses in London, I have seen plants beautiful and flourishing; but never as a matter of "luck," but always the consequence of care, cleanliness, and good management, commingled with something of the enthusiastic for all that pertains to vegetation. Nor is this all. Whatever there may be in the strange principles of mesmerism, there can be no question, that the tending of plants from love to them, will always exert a softening and refining influence upon human character. Without that love, plants may be well grown as a matter of speculation and trade, but without it, and no pecuniary object in view, we shall see little of fine gardening in our cottage windows. This becomes a matter of no little moment, if it be true, as we contend it is, that the condition of a garden, and the state of the window plants, form no bad criterion of the tastes and aspirations of those who reside within. Would that Britain's daughters would clearly see how easily youthful swains "might thus take their notes," and read their character.

Our Editor might well say it was difficult to please every one. Some have complained that we devote too little attention to this interesting subject; while others, again, say "You are always dabbling about the windows, as if there were no other place in which to grow and keep plants; can't you present the subject under entirely new features?" There is the difficulty. It is an easy matter to fabricate, or borrow a new idea, and back and ride it right valiantly, heedless of consequences; but, much as we like novelty, we like those things that are practically demonstrated much better, and writing for the *practicals*, truth obliges us to say, that in this window-gardening concern we are really at a standstill for the *novel*. Almost every plant most suitable for window-gardening has been mentioned; the mode of cultivation alluded to; everything connected with economy, taste, suitability to the circumstances, adverted to and elucidated; and I hesitate not to say, that the various papers scattered through the work, if collected and arranged, would constitute the best treatise on the

subject that has ever appeared. Then why allude to the subject now? Many reasons might be given. Let three for the present suffice. Many are now trying their hand who have read but few of these papers. Many say that they have *tried* hard to work according to rule, and yet have not fully succeeded; and many, again, care less for winter display than making their windows repositories for plants to bloom out-of-doors in summer. From what we have been told, and what I have seen, I can clearly see several causes of failure, and these obviated, as many means of success will be secured. We may so far avoid the one, and secure the other, by attending to the following propositions or directions.

First, *House the Plants, or get them under shelter early in October*. In the northern counties temporary protection should be secured by the end of September. Few window-gardeners will content themselves with one set of plants for the season. They best show their knowledge who can have their windows always fresh and gay with successions of plants and bloom. For this purpose many things may be kept out-of-doors during the summer, and in many cases, cuttings taken from flowering plants in spring will beat their sires in autumn. In a warm, dry autumn, the longer the plants stand sheltered in the open air the better. Their stems thus get more thoroughly matured. Some, of course, want more hardening than others. I lately mentioned all the broad sectioned tribe of Cacti-Epiphyllums as being well-suited for window-gardening. Their blooming well in spring and summer depends on the quantity of bright light that plays on their stems during the previous autumn. Clear sunshine, and comparative dryness at the roots, are the things to aim at. A soaking at the roots *now*, would give so much moisture to the stems, that the muggy atmosphere of a whole winter would scarcely evaporate it. A very little frost would also injure the embryo-buds, though as yet next to imperceptible. Geraniums and other things are also injured by both such means. A miserable sickly hue during the whole of the winter is often the result of a few hours frost or sleet in autumn. If circumstances compel you to keep your plants out late, provide a temporary covering that you can throw over them in a moment of emergency. A light shed, an empty room, anywhere, where light and air can be given, will be a more secure place than out-of-doors, after the commencement of this month. Plants, however tender, will stand a great degree of cold, if they are dry.

2ndly, *Shift and pot early, and, as a pre-requisite, strike cuttings early*. Plants, whether old or young, if growing freely, and fresh roots reaching the sides of the pots, will stand rougher treatment, and require far less trouble in winter, than plants whose roots are beginning to move into fresh soil. Every little oversight, such as too much wet or too much dryness, a moist atmosphere or a dry one, a cold air or a warm air, are apt to be injurious to the latter. The poor things resemble a man with several enemies, who has got no wall against which to plant his back,—no firm yet gently-yielding ground on which to rest his feet. The transplanting of a cutting, or the shifting of a plant pretty well established from one pot to another, always is accompanied by a check to the growing principle. Where conveniences exist, we neutralize these as much as possible by close pits and shading, to lessen evaporation, until the roots are again fairly at work, and thus we submit to a present inconvenience in hopes of obtaining a future advantage. But our window-gardeners are, generally, not overburdened with conveniences; and their only chance to have plants in a nice healthy state in winter, is to pot little after the first of September. It is true, many things may be potted now, but they must rather be viewed as reserves for the future than ornaments for the present.

3rdly. *Bulbs, such as Narcissus, Tulips, Hyacinths, Crocus, &c.,* to bloom in winter, or, rather, in windows in spring, should be potted early likewise; and when placed in a cellar, or in a corner of the garden, covered over with ashes or dry earth. The pots may be brought in to the window when the pots are filled with roots, and the leaves and flower-buds appearing. A slight shading will be wanted at first; a paper funnel, the broad end over the pot, and the small end with a hole in it to admit a portion of light, is useful for this purpose, and also for drawing up the flower-stems of Hyacinths, so as to give the florets room to expand.

4thly. *In potting in autumn, use uniformly light, sandy soil, in rather a rough state.* That which may be obtained by the sides of highways, as the accumulations of road-drift and scrapings, *old* and well aired, will grow nineteen-twentieths of the plants usually cultivated in windows. A little rotten dry leaf-mould may be added if come-at-able, or even a little sandy peat, or a little broken charcoal; but rotten dung should never be used at such time as a component of a compost. If extra vigour in particular cases is required it can always be given by surface-dressings, or manure-waterings. Many render their plants sickly by placing crude matter about their roots, which, when water is applied, gets into a sour soapy mass. They treat, in the short days of autumn and winter, a pot plant in a window, just as they would treat a cauliflower plant in summer. The growing and the flowering principle are just at the antipodes of each other. *Robust, rather than luxuriant, vigour—the greatest quantity of bloom in the smallest possible space—ought to be the aim of the gardener.* Need I say that the pots should be drained so that the water passes easily through them.

5thly. *Water carefully.*—Easier said than done. Water thoroughly when you do water, so as to reach every fibre; wait patiently till the plant is dry, and then repeat the operation, is the whole principle involved. And yet, how few understand it; or, if comprehending it, practice it. I believe that nine-tenths of the deaths of plants in pots are owing to the water can. The reasons of this have been fully explained. The dribbling system, in course of time, leaves the mass of roots as dry as an unused whistle, while at the surface there is a continual struggle between roots being scorched up at one time, and making fresh efforts for existence at another. To the question so very often put, "How often shall I water my plants?" no more definite answer can be given than, "Just when they need it: let them drink only when they are thirsty." Heat and light, the perspiring processes going on, the state of the plant—whether growing or resting, whether in bloom or maturing its growth, whether succulent-stemmed or hardwooded—must all be taken into consideration, and then it will be seen not only that there is a little philosophy in the growing of a plant, but that the plant that may require a refresher twice a-day in July, may be amply supplied with twice a-week in October, and twice a-month in December. As a general rule, unless when flowering or showing bloom, succulents will require little water from this time until April. On the same principle, Scarlet Geraniums will suffer less from dryness than florists' Pelargoniums; and these, again, will not suffer so much as the harder-stemmed fancy varieties. From this time until May the water used should be soft, well-aired, and not lower in temperature than from 55° to 60°, unless in particular cases, such as when a plant has become very dry; little or no water should be allowed to stand in the saucer, never to rise higher than half the height of the drainage during the dark months.

6thly. *Strive to keep the plants in small pots.* You will not only thus save room, command the greatest amount of bloom in the space, but have the means of arranging your plants in fresh combinations, in vases, boxes, or

baskets, in moss, &c., at pleasure; and thus the watering be reduced to a minimum of labour and care.

7thly. *Never hesitate to sacrifice a small present pleasure to realise a high future enjoyment.* Here is a Fuchsia, beautiful in summer, has still a few flowers at the points of its shoots, and for the sake of a flower then and now, you are to keep it in during the winter, though its thin and sickly foliage already gives one the blues. If turned out in the sun a month ago, housed any where from frost in winter, pruned, and fresh shifted in spring, you would have had something to look at next season. Here is a Pelargonium, lanky and bandy-legged, having a few stray flowers since August. What can you do with it now? If you cut it down, it will be mid-winter before it breaks, and how wretched-looking before. The cuttings will be useless, or involving more trouble than they are worth. If that plant had been cut in, pruned in July or August, the cuttings would have been nice little plants now if you wanted them. The old plant would have broken afresh; you could then, by removing the old soil, have shifted into a similar or a smaller sized pot, have had a pretty bush to survey all the winter, and the hopes of a fine sight in spring and summer.

8thly. *Never, if possible, give a check to roots and branches at the same time.* Our last example of the Geranium will shew this. We prune back the unutilized roots and stem, cause fresh roots to be produced, and when these are several inches in length, we slightly prune and disentangle the roots; and the young shoots, by a reciprocal action, cause fresh roots to be formed. Now we might prune the top, and fresh pot at the same time, and yet succeed; but we should lose time by the process, and in delicate cases lose the plant too. See, some time ago, some most valuable suggestions on transplanting, by Mr. Beaton.

9thly, and lastly for the present. *Attend to cleanliness.* Look on the leaves of plants as performing functions analogous to that of your own lungs; and a covering from dust will be secured for them at one time, and a sponging with tepid water no stranger at another. And the best of it all is, that the more trouble you bestow on your pets, the better you will like them. R. FISH.

JOTTINGS BY THE WAY.

(Continued from vol. viii., page 415.)

OSMASTON MANOR, THREE MILES FROM ASHBOURNE, DERBYSHIRE, THE RESIDENCE OF F. WRIGHT, ESQ. Mr. Lamb is gardener there.—This is quite a new place. We have already noticed it when writing on Coniferæ, showing how they have planted a considerable number of *Cedrus Libani*. We have now to add a few notes on the new gardens. The vineries are built on the same plan as those mentioned by Mr. Fish, at Kingston, in a late number—that is, a rather flat ridge-and-furrow-roof. The vines are progressing favourably. In the centre, across the house, is a strong shelf; on this shelf Mr. Lamb had placed vines in pots, which produced some fine fruit, of a good colour, and excellent flavour. The vinery, for there is one finished, is made use of as a plant-house as well, and had in it some well-grown specimens of stove plants, particularly *Alamanda cathartica*, *Echitis splendens*, *Stephanotis floribunda*, *Schubertia graveolens*, *Raphistemma pulchellum*, and several species of *Æschynanthus*, all in flower. There is also a range of plant-houses, one half of which only is complete. In a stove house we noticed a very fine spike, with several branches, of that difficult orchid to bloom, the *Renanthera coccinea*. The plant was healthy, and of a dark green. The method of causing it to bloom was first to grow it freely, and then give it a severe rest. *Oncidium papilio*, the best variety, had seven

blooms expanded, and was a large, healthy plant. The collection of orchids, however, is but small as yet; but it is intended to increase them much as soon as the entire range of plant-houses is finished. In the greenhouse the *Mandevilla suaveolens* was finely in bloom, also a good specimen of *Solanum jasminoides*, and *Kennedyia Maryattii*. There was also several standards of that fine old plant, the *Olianthus puniceus*, which is a novel but very striking mode of growing this plant, worthy of imitation. In an old greenhouse near the mansion there was a fine standard, in full bloom, of *Bignonia grandiflora*, with its large, trumpet-shaped flowers. The stem was more than six feet high, and the branches drooped round it in the umbrella form. It was a striking and ornamental object. In the centre of the garden is a very remarkable object—a lofty stone tower, with a winding staircase, which leads to the top. From this elevation splendid views of the surrounding country are seen. The use of this lofty tower is to convey away all the smoke, not only from every fire in the garden, but also from the dwelling-house, or mansion; so that there are no chimneys to be seen on the premises; yet, though cooking was going on in the kitchen, very little smoke appeared to issue from the tower. We had the privilege of seeing through the house, and were much pleased therewith. Everything is on the largest scale to save labour. Ascending and descending platforms convey coals, and every other needful thing, to the level of each tier of rooms. Water, too, is conveyed by machinery, and every possible convenience is managed on the most approved modern practice that science and skill can bring into play. Indeed, the description of this place, from the number of interesting and useful objects in it, would fill a rather formidable volume, especially when everything now in contemplation is finished.

To return to the garden. The garden walls are hollow, and near the ground have hot-water pipe inside the hollow to heat them. These answer well. Though the peach-trees have only been planted three or four years, they were bearing some excellent fruit, and were very healthy and vigorous. The walls are covered at the top with a projecting iron coping, with contrivances for hanging protecting material; canvass, for instance, from them down to the ground. An excellent plan. The trees are trained to iron-wire-rails, stretched out against them, and about eight inches apart. There did not seem any difficulty about training them, and they are certainly neater than the old method of nails and shreds.

The next place we visited was *Rolleston Park*, the seat of Sir Oswald Mosely, Bart. Mr. Atkinson is the gardener. This place we have often referred to, on account of a remarkably fine *Abies Douglassii*, and *Pinus Sabiniana*. Both these fine specimens continue healthy, and are progressing quickly. The *Abies* is now nearly forty feet high, and twenty feet through, very densely clothed with branches. The *Pinus* is quite as high, but is not so dense; the stem is full three feet round. There is also a good specimen of *Abies Menziesii*, fifteen feet high, and many others very interesting, which our space forbids us to dilate upon. We must, however, mention, that on the walls in the kitchen-garden was a large crop of excellent peaches and nectarines, and a great crop of melons in the pits.

On the front of the vineries is a large square of ground planted as a botanic garden, according to the natural system of Jussieu and Decandolle. Sir Oswald Mosely is passionately devoted to his garden, and is a fine old English gentleman, even of the present day. The place is well worthy of a visit. The gardener, Mr. Atkinson, has been there about twenty years, and is a man of science and unassuming manners. He has a very respectable collection of stuffed birds, all cured and set up by himself during his leisure hours. It would be

most beneficial if every gardener was encouraged to do so likewise.

T. APPLEBY.

(To be continued.)

THE TALL LOBELIAS.

THAT these are florists' flowers, in the sense that term is used, there can be no doubt. Mr. Glenny's rules, by which we may distinguish this class of plants, are—1st, The power to be perpetuated and increased by slips, and other modes, independent of its seed; 2ndly, The power to produce new varieties from seed, capable, like their parent, of being perpetuated; and 3rdly, it must possess sufficient interest and variety to be grown in collections. That these rules are just and correct, we need only glance at such plants as *Calceolarias*, *Cinerarias*, *Carnations*, *Dahlia*s, and the like.

Though the Tall Lobelias have never, that we know of, been shown in collections, or had prizes offered for them, yet there is no reason why they should not. In respect to brightness, and variety of colours, they are surpassed by few, especially in that always-admired and far-off-to-be-seen colour, scarlet or crimson. That they may be greatly improved is certain, from the progress already made; witness the variety named *Queen Victoria*, compared either with the original species when introduced from Mexico, and named *Lobelia fulgens*, or with the old *L. cardinalis*. With regard to diversity of colours, we have already a goodly assortment, ranging from pure white to pale blue, dark blue, purple, scarlet, and crimson. There is variety enough even at present; and if our indefatigable friend in such matters, Mr. Beaton, would try his practised hand at them, we have not the shadow of a doubt but he would, in a few generations, produce all the colours of the rainbow. When I have got over the hurry-scurry of establishing myself in my new occupation, I shall try my unskilful hand at them, and trust many of our florist friends, with their usual perseverance, will also work in the same field, and I am sure then we shall have a very superior race of tall Lobelias.

To forward so desirable an end, I shall write a few brief papers on this fine race of really showy plants, whether cultivated in pots to be exhibited in collections, or as ornaments for the flower-gardens, grown in masses in, as it is called, the bedding-out system; and for this latter purpose Mr. Beaton will wish every success.

There is no doubt that the hardy species from North America will hybridise with the more tender ones from Mexico; and thus we shall attain, in a great degree, another desirable object—the acquisition of a more hardy race. Botanists rejoice when their specific distinctions can be preserved intact, and in the case of orchidaceous plants they are quite safe; but there is scarcely any other tribe of plants with which the hybridiser does not make sad havoc (as they think) with pre-conceived notions; so that at this day there are thousands of so-called species that may be changed, and, as far as beauty of colour, form, and substance are concerned, be improved, by cultivation and cross-breeding. This improvement has been, and will continue to be, a source of never-failing, innocent, healthful, and amusing occupation to hundreds of human beings. Premising thus far, we shall return to our object—the cultivation and improvement of the Lobelia.

As there is nothing like order in every proceeding, I propose to arrange our subjects under the following heads:—1st, Propagation, by seed, by cuttings, and by division; 2nd, Soil; 3rd, Cultivation in pots for exhibition; 4th, Hybridising; 5th, Preserving through the winter.

Propagation by Seed.—As these Lobelias flower late in the year (that is in August), by the time the seed

is ripe it will be too late to sow it, unless the raiser has the convenience of a greenhouse. I will, in the first place, suppose he has not, then the seed must be gathered, cleansed from the seed vessels, and carefully preserved in paper in a dry, cool room, till March; then prepare some light soil composed of sandy loam, vegetable mould, and sandy peat, in equal parts. Mix these well together with the hand, and let the soil become partially dry; then shift a portion of it, for the surface, through a fine sieve; reserving the parts that will not go through the sieve. Procure some wide, shallow pans, with a hole in the bottom to let out the superfluous water; place over the hole a large piece of broken potsherd, or an oyster shell; then cover the bottom of the pan with a layer of smaller potsherds, and upon them put an inch or two of the rough siftings of the compost; press this down level and firm, and then place upon that a layer of the compost unsifted; let this layer very nearly fill the pan. Upon that, finally, put a thin layer of the sifted compost, level it down, and press it gently with a smaller pan, or a round, flat piece of wood made on purpose. Then water gently, but sufficient to wet the whole thoroughly through. Let it stand an hour, to allow the water to settle through, and the surface to become partially dry. It is then ready to receive the seed. As this is almost the smallest of all seeds, it must be, as it were, dusted over the surface, and some very fine powdery compost dusted as thin as possible upon it. Press this very lightly upon the seed, but give no water—the moisture in the soil below will ascend and moisten the seed and its light covering sufficiently for the time. Place the pans in a cold frame, or, what is better, upon a very gentle hotbed, under glass. If the cultivator has a greenhouse, the seed may be sown as soon as it is ripe, in the same manner, and be placed upon a shelf near the glass. In either case, as soon as plants come up, and can be handled, prick out the seedlings thinly in other pans prepared similarly to the seed-pans. There will be this advantage in the autumn-sowing, that the plants will be forward enough to plant out in nursery beds earlier in the following season than the spring-sown ones. It is very likely some will flower that season, and the best only should of course be kept, the rest will do to plant out in the borders of the flower-garden, or be thrown away at once. Such as do not flower should be taken up in the autumn, potted in small pots, singly, and placed either in a greenhouse near the glass, or upon a bed of coal ashes in a cold frame, well protected from frost till spring, when they should be planted out again to prove them.

T. APPLEBY.

(To be continued.)

CONIFERÆ.

(Continued from page 10.)

CUPRESSUS LUSITANICA (Cedar of Goa, or Portuguese Cypress).—A very elegant drooping tree, fifty feet high, grown extensively in Spain and Portugal, hence its specific name. It is not hardy enough to bear the severe cold in the northern parts of Britain, but would, very likely, be able to live in Devonshire and Cornwall near the sea.

CUPRESSUS MACROCARPA, *syn.* **LAMBERTIANA** (Large-fruited Cypress).—This is a noble tree, growing upwards of seventy feet high, with a stem nine feet in circumference. The leaves are rather broad compared with the rest of the species in this genus. They are of a bright green on the upper surface, and of a silvery, glaucous hue on the under. This peculiarity renders it a fine tree to ornament the landscape in this country, as well as a desirable species to introduce largely into the pinetum. The timber is hard and close-grained, which

quality, when the plants are cheaper, will make it valuable as a forest tree, especially as it has proved to be perfectly hardy. Mr. Hartweg found it in California, and says it forms one of the noblest trees in that country, and when fully grown bears a strong likeness to the majestic Cedar of Lebanon. We strongly recommend this beautiful species to the lovers of Coniferæ. The price is moderate; good plants, two feet high, may be had for 2s 6d each. There is a variety named *fastigiata*, a closer-growing and more upright tree, equally hardy, but more rare.

CUPRESSUS MAJESTICA (Majestic Cypress).—A tree well-named, if we may judge from the growing appearance of the young trees we have in this country. Very little is known about it; even its native country and origin are unknown. It is very rare.

CUPRESSUS THURIFERA (Frankincense-bearing Cypress).—A perfectly hardy, fast-growing tree, native of Mexico; in that country it often reaches one hundred feet high. The habit is different to the generality of Cupresses, being thin of branches, and small-leaved, yet it forms a fine tree. We have seen specimens of it about fifteen feet high, quite upright, and very handsome. Though a native of Mexico, it bears our climate well, growing in any soil not actually wet.

CUPRESSUS THYOIDES (White Cedar, or Thuja-like Cypress). This common tree has been separated from the Cupresses by Spach, a writer in a French work on botany, as, we think, quite unnecessarily, and, therefore, we have retained it under the genus where Linnæus placed it. It is, as is well known, a beautiful tree, growing upright, and thickly clothed with branches and foliage, so much so, that no object can be seen through it. This renders it useful to hide any unpleasant, low building, or other unsightly object. It delights in moist soil in America, its native country, but will thrive with us in deep loamy or sandy soil. The wood is fine in grain, soft, and light, and easy to work, and will bear without warping great extremes of drought and wet, hence it is highly valued in the western hemisphere. In this country it seldom reaches more than thirty feet; but in the swamps of America its altitude is often from seventy to eighty feet. In the grounds at Elvaston Castle, in Derbyshire, the variety named *O thyoides variegata* is planted in a close row to form a hedge, and a beautiful object it is. This variety, intermixed among other low-growing green Coniferæ, makes a pleasing variety. There are several more varieties named—*glauca*, *nana*, *Kewensis*, and *atrovirens*—which, in large collections, are desirable enough to cultivate as objects of curiosity.

CUPRESSUS TOROLOSA (Twisted Cypress).—This is an eastern species, growing in Nepal, on the Bhoton Alps. Mr. W. Appleby, the son of the writer of this article, Curator of the Punjaub Horticultural Garden there, describes this tree as being one of the finest objects in that country. The garden is situated about sixty miles from the Himalayan Mountains, the native habitat of the elegant *Cedrus deodara*. Like that handsome tree, the *C. torolosa* is hardy enough to brave our winters, at least, in the south, and is a truly beautiful and ornamental tree. Every collection ought to possess several specimens of it. It has been raised plentifully from foreign seed, and is cheaper than the *Deodar*. Plants well-rooted, three feet high, may be had from 2s 6d, so that no one need be without it. As a single plant on a lawn, it rivals any other species of Coniferæ in beauty. It loves a dry soil, and thrives in a high situation, if protected slightly whilst young. The timber is excellent, being close-grained, and capable of a high polish, rivalling in value the wood of the *Deodar*. As the plants are so reasonable in price, and the timber so valuable, it is worthy of the attention of planters on a large scale, especially on the high waste lands of Ire-

land and the southern counties of England. If our large landed proprietors were to plant largely this species, *Cedrus deodara*, and other new and valuable cone-bearing trees, nurserymen would import seeds more largely, and sell them still cheaper, to meet the demand. Our grand-children would then see quite a new feature in the landscape of the country, as well as be in possession of greater variety of valuable and useful timber.

CUPRESSUS UHDEANA (Mr. Uhde's Cypress).—A native of Mexico, where it grows to sixty feet high. Very unlike the rest of the genus in appearance, growing very fast, but not quite hardy enough to bear the open air. It is, however, a desirable, handsome plant for a conservatory or a crystal palace, like the one now erecting at Sydenham.

T. APPELBY.

(To be continued.)

NOTES ON THE CABBAGE TRIBE.

It would, no doubt, be somewhat interesting, were we able to trace the history of many of our most useful fruits and vegetables, from the period when they first afforded our fore elders that scanty meal which the backwood Indians are at the present day obtaining from natural productions, and which may hereafter assume a widely different appearance, when subjected to the skilful-directed cultivation of centuries yet to come. But whether the wild fruits of the unexplored forest, or that "herbage on which so many of the human race have been accustomed to look for sustenance, be ever destined to become the parents of families that may compete in usefulness with our corn, rice, fruits, and vegetables," as already known to us, is a problem to which the boldest of us cannot venture on a solution. Be that as it may, there is no doubt but many natural products might be so far improved by cultivation, as to increase their usefulness to the wretched inhabitants of those countries where civilization has not yet introduced anything better; but whether the restless enterprise of the "white man," will direct itself to the improvement of those native products, or be content with driving them before him (as he has been accustomed to do the "natives" themselves), and supply their places with things he has been taught to look upon as forming all that is useful in life, is more than any one can now venture an opinion upon, as it is a notorious fact, that notwithstanding the spread of civilization, and the increased comforts, which, as a nation, have been gradually pouring in upon us during the last three centuries, the number of plants from which these necessities or luxuries have been obtained has received very little addition the whole of that time. If vegetables be more plentiful in England in the nineteenth century than in the sixteenth, it is only, or nearly so, that the same kinds are more extensively cultivated now than formerly. Discovery has added but little to our stock, and cultivation has been more directed to the improvement of what we have, than in searching for new objects of a useful kind to work upon. Now, though I do not disagree with those who so laudably endeavour to carry on improvement to the highest possible standard, yet I think we ought not entirely to forget new objects, and those who struggle, however ineffectually, to render them serviceable to our use, are entitled to our warmest thanks; as, notwithstanding the tardy progress they may make, if the object they have in view be a deserving one, success will sooner or later crown their efforts. It may be true, that certain lawgivers will pretend to hem in the field of improvement, by pointing out how far it is possible to go, but even their lines of demarkation are so remote, so ideal, and so often over-

come, that no real benefit can be had by attending to them. Amongst other "fixed laws," it is "laid down," that cultivation weakens the constitution of a plant:—renders it less able to endure the rigours of winter, and prevents its living to so great an age. To the former of these restrictions, might we ask, how does it happen that those valuable stone-fruits of ours ripen so well, and stand our winters, when they are natives of a warmer and more sunny clime? The limited period at which a variety will continue to be profitable, is, however, certainly a proof that cultivation has here extended its favours at the sacrifice of the producer's existence; but this is more than compensated by their increased usefulness, so that it has been laid down as a rarely deviating law, that whatever tends to an early development, has a like influence in hastening to an ultimate end. Fruit-trees that become fruitful at an early age are rarely long lived, and the same with other things. Now, this law, as well as its various ramifications, has been taken advantage of by those who have studied our garden politics, so that they have been able, every now and then, to "report progress," in the shape of a production differing in some respects from the materials they had obtained it from. That this is daily accomplished, is manifested from the many varieties of fruits and vegetables we now have offered to our use, though it cannot be said that all are improvements, neither are they always different from those which preceded them; but that mighty judge, the public, soon discards what is spurious or indifferent, so that only the best is at all patronised, after a trial has been made.

In taking this cursory view of what cultivation has done, and is doing, in the way of changing the constitution or habits of some of our most useful vegetables, I have done it for the purpose of calling attention to one of the most important in the class—the *Cauliflower*. This delicate member of the large Cabbagewort family would seem to have had a common origin with the cabbage, and other species, but by a series of patient "breeding-in-and-in," the old characters would seem to have been overcome, and while the Cabbage, as one branch of the family, has been coaxed to conform to our wishes, by presenting us with a mass of its foliage folded in beautiful order into a globular or conical-shaped parcel, the Cauliflower has been directed to take another turn, and taught to form its embryo flower-buds into that close compact form, which we term "a good head." Other variations of the uses of this all-important family might be adduced, but the above is sufficient to prove the wide range which cultivation is capable of taking, and the consequent results. Now, though they may possibly both claim a common parentage, yet there is a considerable difference in their hardihood—the cabbage standing unscathed where its kinsman would have perished. That this difference is brought about by the cultivation of the latter being directed to the most delicate part of the plant, is certainly the cause of this want of hardihood; but be that as it may, the difference in the two, amounts to something like three or four degrees of latitude, or more; other conditions being the same. By this it will be seen that Cauliflowers ought to exist or stand the winter in the south of England without any more protection than is necessary for cabbage plants in the north of the kingdom; and though there is often a little more difference still, yet the principle is correct. But the two productions are essential at the same place, consequently, the more tender one must be protected through the inclemency of our winters, while the more robust, being left to brave the storm, may, nevertheless, endure its rigours with less injury than its sheltered kinsman. Cauliflowers are, however, ticklish things to deal with, and some other conditions must be complied with, to ensure a successful result; but the subject is one so fraught with

importance, that I find the subject of wintering them must be postponed for another week; in the mean time, let our less experienced friends take care not to nurse these plants into that tender state which makes them as susceptible of cold as if they had been denizens of the greenhouse. A sturdy, healthy growth can only be ensured by continued exposure, and let them be only covered up when the weather threatens to become very severe. But more of this anon. J. ROBSON.

THE WIDOW INDEED!

By the Authoress of "My Flowers," &c.

It is remarkable to observe how unwilling people are to trust in God. If *our own* hearts did not teach us this, we should be quite ready to say the whole world is beside itself, for having such large and full promises given to it, and yet refusing to receive them. And so it is; it is mad, and guilty too; but we are all in the same condemnation. There is scarcely one among us who would dare to rest upon one of God's promises if it went against the promise of the world.

I know, however, one old woman who has dared to do so. She has acted upon, as well as talked about, trust in God; and though she "was young, and now is old," she has not found the "promise" fail.

Old Betty is a widow of above fourscore years: she is, in fact, eighty-nine. She was quite a young woman when her husband died, and left her with two daughters and a son; but he left her with the "promise," also, and he could not have done better for her. A man who had had an affection for Betty in her youth came forward, in due time, and wished to make her his wife. She had no objection to him in himself, but she loved the "promise" better; and chose to abide "under the shadow of the Almighty," who had seen fit to take her earthly prop away. Two or three times Betty was urged by this old admirer to change her mind and marry him, but nothing could move her. She said she was not "afraid but the Lord would provide her a bit of bread," and take care of her children too—and a widow resolutely she remained.

Her eldest daughter married, and died young. The younger became a cripple, from rheumatic gout, and lay for years and years cramped and agonized on a little bed in the corner of the kitchen, with her hands and feet twisted almost into balls, and suffering the most acute pain. She died soon after we first knew the little household, but I can still hear the bitter cry of "Moth-the-r, moth-the-r," which the poor sufferer constantly uttered, as she lay in unspeakable torture. Poor Betty waited upon her by night and by day; she was a tender mother, and did all she could to soften the trial of this poor afflicted creature, but nothing could ease the pains, until the Lord stretched forth His hand and took her.

Betty's son was a "waif and stray." He was wild and worthless in every one's opinion but hers. He was transported after the Riots of 1830; and, excepting two letters that came soon after his going away, she has heard nothing of him. Whether he died, or forgot her, she cannot tell. His term of transportation has long since ended, but he neither comes or writes; and Betty weeps bitter tears over his loss, and her own uncertainty.

The "promise" has never failed poor old Betty through all her trials. When Naomi was left desolate, a daughter-in-law clave to her, and cherished her; in Betty's bereavement a son-in-law became to her as her own, and clave to her with the fond affection of a daughter. He never left Betty's roof from the hour his wife died. He never dreamed of marrying again; he had no child, and Betty was thenceforward his only care. When all her children were swept away, George stood in the gap; he laboured for her, he comforted her; he was a man of few words, but of many deeds, and he cheered and supported her desolate widowhood.

Betty was enabled to turn a penny honestly, by selling a little gingerbread, and a few apples and potatoes in their season. There is always something to be seen still in her window of that kind, although, in these days, she finds

pennies are few among her humble customers. A daily walking carrier from the town has for many years spent his mid-day hours in her cottage, for which he pays a trifle, so that Betty has added her mite to her son-in-law's labours to pay their rent and live. Cleaner or more honest creatures than the widow and her devoted son-in-law the parish never produced. George worked for years on a neighbouring nobleman's estate, and not a word was ever spoken against him. Those who knew him could trust *him*, where none else could be trusted; and he was so civil, so harmless, and so humble, that every one liked and respected him.

But, alas! this comfort has been disturbed in the good and wise providence of God. The aged widow now dwells alone in her little cottage. Her second prop has been taken away, and she rests singly on Him who says "Let thy widows trust in me."

It was a bitter parting. Poor George had been a great sufferer at times for many years, but his last illness was very severe, although he seemed better, and Betty had no idea of his end approaching. He called her up one night in a great hurry, but had nothing to say when she went to him. He was odd in his manner, but still she was not alarmed, and when he wished for a cup of tea, she went down stairs to make a fire, little supposing that on her return she should find him dead. But it was so. The kind eyes were closed, the active arms were still, the voice that was always welcome to her was silent, and poor Betty found herself again a childless widow.

The poor old woman still clings to the "promise," and as she relates the short and simple story of her life, she blesses God for his goodness in never having left her to want. Her mouth has been filled, although with homely fare, bread has been the chief part of her diet, with the weakest liquid that could be called tea, and what causes her heart greatly to rejoice is, that she has never been in debt. She pays to the uttermost farthing every thing she owes, and while a shilling remains owing at the shop she is restless and uneasy.

Her prospects on earth are now somewhat dark. Her rent is high; the carrier's health failing, which would cut off one little means of help, and the failure of potatoes in her little bit of allotment ground, depriving her of that principal support. But her friends, who love and respect her, take no rent for her ground, and she cheerfully says "The Lord will keep me;" and has no excessive dread of the Union, should it please God to bring her to that end. But as yet she holds quietly on her way. She does all her little household work; washes her own clothes; rises at five as usual; and "muddles about" as she says, all day long. It is affecting to see her sometimes looking over all poor George's working tools, which she hopes to sell—a little story belongs to almost all of them; and she seems to see him again seated by the fireside as she spreads them out before her. She is now unable to reach the church, but a lady goes every Sunday morning to read a portion of Scripture, and a simple sermon to her in her little dwelling; and she loves to listen to the Word of Life more and more, now that all other things are passing away. She has a good hope through grace—she has tasted the Word, and found Him "faithful that promised;"—"bread" has been given to her—"water" has been "sure" to her—she has wanted "no good thing." Young and old have died around her—the changes and chances of this mortal life have happened to rich and poor, but old Betty stands like an aged oak, with a twig or two still green, just where she stood more than forty years ago; her head is strongly bent, but her eye is bright, her actions vigorous, and her affections warm and strong. She is now asking anxiously after a young midshipman, who is on his homeward voyage, who has grown up before her eyes, eaten her gingerbread, and waved his sea-cap twice to his old friend, as she stood weeping at her door to see him depart to his ship. *Her* son is lost to her, but she loves the sons of others; and there are some whose first visit, on returning home, is paid to poor old Betty.

There is no fear for those who are "widows indeed," who trust in God, and continue in supplications and prayers night and day. They have a treasure-house, and a key that unlocks it; they have a God, and a way of access to him; they have a promise, and a faithful Promiser. No man can meddle with their promise "or their peace. The Word of the Lord hath said "Let thy widows trust in me." "Heaven

and earth shall pass away," but God's "Word shall not pass away." Let the example of poor old Betty encourage all widows to *trust in God*.

COTTAGE GARDEN, AND WHAT SHOULD BE THE NOVEMBER CROP.

BREADTH, 27½ YARDS; LENGTH, 44 YARDS.

East hedge.

Alley and Raspberry border, 6 feet.

Cabbage tribe succeeded by next spring and summer's mixed crops.

	feet.
Two rows of prickly spinach	4
Alley	1
Three rows of spring brocoli (Knight's Protecting)	9
Alley	1
Three rows [Apple tree] of early spring cabbage	6
Alley	1
Four rows of Scotch kale	12
Alley	1
Two rows of savoys	4
Alley	1

.....
Potato division (autumn-planted).

Sixteen rows of potatoes, at 30 inches apart

Apple tree.

.....
Succession winter division following the mixed crops, and to become occupied with the roots next season.

A flying crop of lettuce succeeded the two rows of spring cabbage, and the row of ash-leaved kidneys, now in their turn succeeded by a trench of parsnips	3
A ridge of turnips (swedes)	4
Alley	1
Two rows of transplanted swedes, or sown turnips	3
Alley	1
One row of [Apple tree] savoys (strong and early planted)	2
Alley	1
Two rows of autumn cabbage	2
Alley	1
Two celery trenches (growing between them a row of cabbage, savoy, or stone turnips)	14
Two rows of strawberries (growing between them white and black Spanish radishes)	7
Alley (or a row of potato onions)	1

Walk, 4 feet.

North hedge.

Walk, 4 feet.

Gooseberry and Currant border, 3 feet.

Nut tree in hedge.

communicate the result of the harvest in Northumberland. The season, though I must call it critical, has been an average good one. The months of July in the gardens, and August on the moors, were very productive, but then many hives had received so severe a check from the miserably cold and rainy weather in June, that they were not in a condition to profit by the succeeding fine weather.

It may not be unacceptable to describe the plan I have pursued, in a locality where the honey season is short, and which has answered so well, that I always intend to adopt it. My hives are Mr. Golding's "Grecian," which I am pleased to see are pronounced by "A Country Curate," the "*ne plus ultra*" of hives. Preferring, as a matter of taste, "the time-honoured straw hive," to those of other materials, it seems to me that the extreme lightness and simplicity of these, with the facility of working them, and having the whole contents of the hive at the disposal of the operator, entitles them to that distinction, while the price places them within the reach of at least a rich cottager. Following the directions in the shilling Bee-book, when the hived swarmed I cut out all the royal cells, and returned the swarm, with its queen. No re-issue took place, and the whole strength of the hive being thus concentrated under a queen two years old, the bees stored 28 lbs. of honey in a super during July. I should add, that I have always found ventilation, and affording additional room, quite ineffectual in preventing swarming.

I am almost inclined to dissent from the sentiment of "A Country Curate," "that there is nothing new under the sun," for the destruction of drones immediately after swarming is a feature in the economy of the bees which I do not remember to have been noted by any author, and its singularity must plead an excuse for a recurrence to a subject which may seem tedious. The early destruction of drones and drone pupa, alluded to in Nutt's book (an appeal to it as an authority would surely be a retrograde step in the path of apiarian science), is what all bee-keepers have experienced in an ungenial season *before* swarming. This year it was seen in many hives, in June, but have we any record not to render its occurrence immediately *after* swarming unparalleled? It would almost tempt me to depopulate a hive, in order to watch the effect on its future prospects. May I say, the idea of a reserve for younger queens is fanciful, those left by the old queen being hatched within at most ten or twelve days of each other, and to the last the succession to the sovereignty is doubtful, as I this year ascertained, for in a hive which did not swarm a second time, the first hatched queen, having disposed of two others, was herself destroyed, when a week old, by one (the last) which had not been liberated from her cell more than twenty hours. Does it ever happen that a stock which has swarmed will swarm again with the young queen, of course after an interval of some weeks? But even supposing such an extreme case, the queen would lay drone eggs before making a deposit in the royal cells.

These observations occupy much valuable space in the pages of THE COTTAGE GARDENER, which, however, are lent to the extension and progress of science, as well as practice, and as the latter must always be dependent on the former, it is hoped they may not be considered inappropriate.—INVESTIGATOR.

SITTING HEN'S NESTS.

A WARM situation has advantages which may not always be foreseen, and the following instance is remarkable, showing how long eggs may be left uncovered without destroying their vitality. I had supplied the eggs (13), and lent a sitting hen to a neighbour, and when she had sat in a granary ten days, was shut out, through the carelessness of a servant. Being a stranger in the farm-yard, the hen was not recognised, but supposed to have strayed in from an adjoining walk, and thirty hours elapsed before it was discovered that the hen had left her nest. The farmer's wife despaired of her brood, but, to her surprise and pleasure, eight chickens were hatched. The tiled roof of the granary was fully exposed to the rays of the sun, and the temperature very high, probably above 80° during the day, and not much lower at night.—INVESTIGATOR, *Lilburn Tower*.

HONEY SEASON IN NORTHUMBERLAND.

THE honey season being over, and the last hives brought from the moors, in accordance with the wishes of some of the correspondents of THE COTTAGE GARDENER, I will

CONFINING BEES.

It is a very singular coincidence, that the hive from which a number of drones were brought out dead, became queenless, as well as Nos. 2 and 13, of "B. B." Its history confirms the opinion of "A Country Curate," that the death of the drones was not the cause of the subsequent misfortune. The drones were brought out June 16th, and the hive swarmed on the 19th, and it is very certain that the old queen would not have left the hive unless the royal larvae had been in a satisfactory state of progress.

Piping was listened for at the usual period, but in vain. Neither was a young queen seen, and as the hive appeared weak and dispirited on the 9th July, the combs were taken up on the bars and examined. Neither queen nor brood being found, a young queen was introduced, and then the hive revived, and on the 5th of August it contained a large quantity of brood, being then sent to the moors; it is now (Sept. 11th) working vigorously in a super. This condition of these hives is not likely to have been caused by the wet and windy weather, as young queens do not leave their hive unless the weather is fine; however, it is not uncommon for a swarming stock to become queenless, and this is not surprising, when we consider the risks to which queens are exposed during their frequent excursions. Some instances of this have fallen under my observation, and perhaps some of the readers of THE COTTAGE GARDENER may be able, from their experience, to give some information on the subject, and also as to what is the immediate effect of a young queen's absence and loss; if it resembles the wild disorder (which all bee-keepers must have witnessed) which takes place when a queen dies in the hive, or is removed after she has begun to lay eggs. This is a subject of importance, to which I have given some attention, and to which I may revert, and should also be glad to learn any observations that have been made on the longevity of queens, whether they have been traced more than four years, and at what season their death usually occurs.

The enquiry of "C. R. R.," July 1st., has just met my eye, and I am happy to be able to answer it. In a hive to which I had returned the first swarm, by taking away the old queen, piping commenced on the 8th day, and, as is usual, with the long note, for the earliest nymph being liberated as soon as she arrives at maturity, is unable to fly for some hours, and the expectant swarm is compelled to wait. There is always piping as long as there is a plurality of nymphs and queens.

May I suggest that the earthenware-pan described July 15th, will not prove a suitable habitation for bees in winter? The non-absorbing quality of the surface will cause great condensation of moisture, and the combs will in consequence become mouldy, and the bees probably unhealthy. Could not these bees now be joined to No. 2, which is no doubt queenless. They might be removed by driving. If a hive of the circumference of the pan is not at hand, a bell-glass or other vessel might answer, by pasting paper over the inside, the bees would probably not refuse to ascend, and then the required weight of food might be supplied from their own honey, with a few pounds of sugar. Six pounds of sugar will yield 10 lbs. of syrup, and though ale may be best, water will answer to boil it in, with the addition of the rum.—INVESTIGATOR.

THE COCHIN-CHINA FOWL'S REMONSTRANCE.

SIR,—I and all our tribe have had our courage worked up to the crowing point by the boastful crow of those Spanish and Dorking cocks of yours, that they and their families are more prolific, eat less food, and are altogether more valuable than we, who have filled so many pockets with the produce of our numerous golden eggs. I am deputed by the rest to deny that we are gourmands, and to say that we eat only in proportion to our size, and that if their wives produce larger eggs, they do not produce so many, nor such rich ones. One of our family was hatched in April, 1850, laid early in August, continued to lay nine out of every ten days, till Christmas, was then broody ten days, laid again in the same ratio till April, 1851, sat three weeks, was then released of her burden, laid

in ten days, and so on. Let them produce one of their family that has done more. Then look at our little ones, how easily reared, while the Spanish tribe are notorious for moping when chickens, and for dying by the dozen. And compare us in size and beauty; some of my wives weigh 9 lbs., 9½ lbs., and 10 lbs., and even 10½ lbs., and several of my brethren weighed 13 lbs., and my father was the same weight. I am glad you will allow me to crow as well as them, and that you do not thrust pieces of wood into my nostrils, to prevent my crowing, as do some of the brutes, who call themselves men, when we are on ship-board. Enjoying this privilege, as champion for our whole tribe, I challenge "Gallus" to a fair and honourable trial of our individual merits, with an equal number of each, equal food in proportion to weight and eggs, and equality in every respect. Mind! I mean *true* Cochins, not mulattos, quadroons, &c., for allow me to say, I have travelled much, and latterly have been invited to pay many visits to professed relations, but was sadly surprised and disappointed to find that the relationship was only this—that some gentlemen from Dorking, and other places in Surrey, had married some of my wives' cousins, and these were their children. At other places I saw the descendants of families who only came from the *same place* as we did. Only think of the impudence of claiming relationship! As well might every ugly cur from the Isle of Skye claim to be a Skye terrier. Pray, Sir, do what you can to prevent this for the future, or I fear these base alliances and assumptions will quite destroy our identity. While I am about it, I'll just ask you another favour. Will you try to invent a poultry exhibition man-trap, for I was once in Sturgeon's prize pen, at Birmingham, and when half asleep, and half awake, at witching time, I think *you* call it, I was disturbed by the introduction of a sly hand into our pen, which withdrew the eggs my wives had laid, marked them, and then did the same with some other pens; these I am told were hatched, and thus my good master's breed was abstracted without pay.

In self-defence, and conscious superiority, I crow defiant,

COCK-A-DOODLE-DO-O-O-O.

SENDING COCHIN-CHINA FOWLS TO THE SHOW.

CHOOSING, catching, feeding, preparing baskets, and directing them, putting in the chickens, and tying down the lids, all is bustle, and the little cart waiting at the gate. The gardener, at present the guardian of the chickens, has just won a *second prize* for flowers. "We must stand *first* this time, Ma'am; good bye, Miss," and away rattles the little cart with its astonished burden. The dear little chickens, how modest, and how pretty they looked! How bright the yellow ones! How decided in their markings; and how bright, too, the partridge! And so they started on their way, to show their beauty among hundreds of the most beautiful in all the eastern counties. So they started. But how did they come back? Looking well and handsome, perhaps handsomer than ever, change of air seemed to have agreed with them; but—chickens no longer—they must lord it now; they must have establishments of their own; they can no longer rest contented, placed apart with pullets, and with cock birds respectively. When let out next morning, the pullets—I love the pullets, pretty confiding, tame little creatures—contented themselves with fluttering all legs and wings across the long grass, "Hock! hock! hock! there *he* is," to where the companions of their recent excursion were confined under a network of wire, and when they found joining company impracticable, returned to eat their breakfast. Not so, the yellow cock. "Young Giant" he had been called before he went, when he was in the habit of being satisfied if he could get his share of the victuals, and avoid the beak of his great red brother; but "Young Pickle" is the name he has gained for himself since he came back, for he has heard of prizes (and done his part towards gaining them, too), he has become self-willed and conceited, he will no longer remain with the cocks. He can surmount, in his eagerness, the little fence which has scarcely ever been surmounted by Cochin-China before, and nothing remains but to give my lord an esta-

blishment of his own. The great red brother, "Bully," is not clever enough to get over the fence, but remains cross, moody, and discontented, on what he evidently considers the wrong side of it. Truly, one of our west country amateurs had good reason for sending his beautiful pen of six young pullets to Birmingham last year.

The poultry exhibitions which now occur so often perform their mission well, occasioning great improvement in all good breeds of fowls; but might they not be made conducive to another?—to a more general, if less interesting, end, by improving the *general stock* of poultry in the country? Let a cottagers' show be carried on conjointly with the local shows, for the encouragement of those who, at present, only want the means to compass the choice varieties. Let a prize of a cock, a cockerel and pullet, or a sitting of eggs of some *first-rate* breed be offered to the cottager who can show a pen of six common fowls in the best health and order, giving at the same time a strong recommendation that for the future, in breeding, the good sort shall be adhered to, and kept distinct. If the show should take place in winter, the eggs might be claimable early the following spring. Some persons, from not having tried the experiment, are fearful of sitting travelled eggs, but they need not be so. Some time back, Mr. Punchard sent me a table of the result of his experience in this particular, by which I find, that out of 901 eggs sent to 63 different places, after travelling distances by sea and land varying between 14 and 395 miles, 555 chickens were hatched; about eleven-eightieths—no bad result. My own experience has proved even more favourable than his, and I have found that eggs which have travelled immense distances, have often produced a larger proportion of chickens than those hatched at home; only showing, perhaps, that when we give a guinea for a few eggs, we bestow more care and attention on them, and the hen in charge of them, than when we merely fetch them from our own hen-house. I am *sure* there are *some*, I have little doubt there are *many* amateurs, who would assist an endeavour like this, which I suggest above, by *giving* the prizes, if the poultry societies could manage the other arrangements, and it would surely conduce towards the result, for the accomplishment of which so many have written and laboured—general improvement in poultry throughout the country. In arranging the details of these and all other shows, the confidence of exhibitors especially, should be supported by the most exact precision respecting the prizes, which should be carefully noted according to precedence, and ties entered as such.

All portions of the country boast their poultry shows now. When will London have hers also? The exigence which still delays a thing so desirable in the eyes of most amateurs, is, I believe, a difficulty in finding some gentleman, with leisure, to undertake the management.

A show of Cochin-China fowls, and no mean one, we shall, however, shortly see in London; but a show without contrast or competition, for on the second of November, Mr. Sturgeon will sell by auction, in Baker-street, a large portion of his far-famed stock.

ANSTER BONN.

(Acting up to the suggestion thus made, our liberal correspondent will offer a cockerel and a sitting of eggs, as a first and second prize, to be competed for by cottagers at the approaching Exhibition of *The Winchester and Southern Counties Society for the Improvement of Poultry*.—ED. C. G.)

THE SHELDRAKE AND ITS HAUNTS.

THE first sheldrake which I ever saw, and the scene in which it made its appearance, remain firmly daguerretyped on my memory, after the lapse of many years. It was my good fortune to be spending the winter in Scotland; and those who have never seen Scotland cannot even dream what a beautiful country it is. I was staying on the banks of that noble river, the Ness, whose entrance into the sea is marked by the town of *Inverness*. The Ness is remarkable for several things: among others, for magnificent salmon. Man gets his share of these fish, but the shoals of seals which haunt the mouth of the river, appropriate the greater proportion of the finny prey. One salmon for breakfast, one for dinner, and a third for supper, is a moderate allow-

ance for each individual of this tribe of seals; because, the meal ended, and his appetite satisfied, Mr. Seal does not put his cold fish, the remains of his twenty-pound salmon, into his larder, but lets it float away for the benefit of the poorer inhabitants of the waters, and amuses himself by catching a fresh one, whenever his mouth begins to water for a little snack. Many readers will ask, *why* we allow this robbery of our salmon fisheries; and why we do not send the seals about their business? But it is of little use arguing, *who* are the rightful owners of the fish, and *for whom* the salmon ought to be preserved—for men, or for seals. A month, on the coast of Invernesshire, will teach the stranger that it is easier to *talk* of dispossessing the seals, than to *do* it.

Salmon fishing, by human creatures, begins there on the first of February. The more snowy and sleety the day, the better luck is expected. That day it *snew* beautifully, as we say in Norfolk; and I think our host caught half a dozen fine fish to his own rod, and could have captured more. I was kindly furnished with tackle, on that and many subsequent occasions. But the Ness, below the falls, is a difficult river to fish, even for adepts; and, till then, I had never thrown an artificial fly, nor seen even a live trout, much less a furious salmon, with the strength almost of a hippopotamus. To do anything in that part of the Ness, it is necessary to throw cleverly thirty yards of line, upon occasion, and to wield steadily the rod which throws it. The consequence was, that the more severely I flogged the water, the less notice would the salmon take of my flies. I sometimes fancied they put their heads out of the river on purpose to laugh at me. Then came a little temper and excitement which made matters worse. At one time, crack went the beautiful fly, of gold and silver and peacock's feathers, off the end of the line, sounding like the explosion from a French postilion's whip-lash; by-and-by, when my energies were collected for a throw which *must* get a "rise," envious shrubs in the background would detain my hook; or the rod would be smashed in two, by the violence of the misplaced effort. I would have given it up, but was good-naturedly urged to continue. Other people caught their salmon; *my* fly never entered a fish's mouth.

The valley of the Ness is lovely at all seasons. Rocks, woods, mountains, a rushing stream, arable lands, meadows, flocks and herds, huts, wreaths of turf smoke, are a few details of the panorama. Fishing soon became, with me, a mere pretence for the admiration of nature. That winter was mild, and often furnished pictures of perfect Alpine beauty: the mountain-tops were covered with snow down to a certain altitude, and then everything was green, and bright, and cheerful, and sunshiny. One day, when I had broken my rod for the dozenth time, I cannot imagine how, and was resigned to the usual good-humoured encouragement to try again next day, I mounted a commanding shoulder of a hill, and sat down to gaze around me. Soon, a beautiful bird came sweeping up the valley from the sea, in mid air, but still beneath me, and followed the course of the river, till it disappeared in the distance. It was a sheldrake, brilliant with orange, white, and some dark glancing colours, I could not tell what. I had read in Willughby, that it was "of a mean bigness, between a goose and a duck," but it looked larger than I expected, from the bright contrast of its hues, which are as conspicuous as those of a magpie, with the addition of greater variety. Tame sheldrakes must be pinioned, or they will afford very pretty sport to your gunning neighbours; and, therefore, in all the aviaries and ornamental waters that I have since visited, no bird of the kind has ever delighted me with a performance resembling that gaudy sweeping flight up the glorious valley of the Ness. I afterwards found that the birds are not uncommon in that neighbourhood, and that they are little sought after by sportsmen. They are good-for-nothing to eat, and their feathers are not usually employed for artificial flies. More metallic tints are in greater request: the poor little kingfisher, not found so far north, yields its skin in England, to be imported into "the land o' cakes." Sheldrakes breed, too, along the coast, in the peculiar spots that suit them, as well as further south. A lighthouse keeper, who had served his turn in the extra solitude of Fern Island, told me that one of his summer amusements was to lay hands on the little sheldrakes hatched there, and to rear them for sale to the dealers in tame waterfowl.

The sheldrake is hardly patronised, as it ought to be, for the decoration of the pond in the pleasure-ground. Orange or bright bay, black or metallic bottle green, and very pure white in the plumage; with bright red bill, and feet, and legs, as Willughby says, "of a pale red or flesh-colour, the skin being so pellucid that the tract of the veins may easily be discerned through it," are not features to be seen in every ordinary farm-yard duckpond. The slight upturning of the bill at the end, gives the same pretty, pert air, as is impressed on the human countenance by a not too snub nose. Both sexes are alike in colouring, though that of the female is less decided. This character, perhaps, also shows their intermediate place between the ducks and the geese: for in the true ducks, however gay the male, the lady is in general soberly brown or russet. I once bought half a dozen sheldrake's eggs in Norfolk (where they have bred regularly on the coast) for as many shillings. They are larger than common ducks' eggs, but otherwise similar: that is, they are of the same shape, tinted with a light sea green, and having a smooth greasy substance. A hen incubated them, and brought off two sheldrakelings, informing us thereby that the little ones are quite destitute of the gay clothing which bedecks their parents. Their down is greyey-brownish-green, like that which covers the goslings of the brown China goose; but they have four lighter yellowish spots, one on each shoulder, and one on each hip, which would help you to pick them out from amongst hundreds of ducklings. After a few days, too, it was evident from their respective increase in size, that one was a little drake, and the other a duck, beginning the world. We reared them to about a month old, when they pined and died. Why? you ought to be able to guess, if you have read Yarrell, and others, on the article Sheldrake. But let us do something better than read. Let us go and visit the breeding places of the sheldrake. We shall then see why Willughby calls them "Burrow-ducks." I am rather in want of a little fresh air, and we shall study natural history after the hunter's fashion.

We are approaching the little fishing-town of Blakeney, and you already perceive a change in the scene. It is a good great-coat colder than at home; and the air is more than transparent. It illuminates the landscape, as if there were some bright medium between it and our eyes, as there is, in truth. These hills are steeper in their declivity than those we are accustomed to: our gravelly crag would not lie at so great an angle to the horizon, but would have slipped down before it became covered with herbage. The material here is well-worn pebble-stones and coarse shingle. You may remember that hills composed of loose matters have a slope corresponding to the stuff they are made of. The ashy cone on the top of Vesuvius is an example which my legs have not even yet forgotten. Different heaps of different rubbish incline according to their own private methods of slope; as would different kinds of sand in different hour-glasses.

A way-side passenger has become a rarity. The few we do meet make a point of saluting us respectfully. Yonder, crouched in the hedge, with red hands and blue face, is a boy deputed to the office here called "keeping" crows. I wonder if he be the same, to whom his employer once shouted, "Well, boy, where are you going to now?" "Why, master, I ha' kept 'em in this piece till they ha' eaten it up good tidily clean. They ha' flown to the tother piece, and I'm now agoin', like winking, to keep 'em there." Observe, too, the cottage gardens. Their contents mark the neighbourhood of the sea. You might suspect it from the extra-bright colours of the few remaining flowers, and from the extreme luxuriance of those rosemary shrubs; but here you see, for the first time during our drive, that handsome plant, the Tree Mallow (*Lavatera arborea*), displaying flowrets not a few. Depend upon it, the "Missis" is finely proud of that ten or twelve-foot specimen. I envy it myself. Those next door are of the same species, though their foliage is so different. Before flowering, the leaves are ample, but when the plant attains its reproductive stage, they are much smaller. In either state it is ornamental, as you see; but though a British native, and even a member of the scanty Bass Rock flora, it is not generally known. Many an alien is more familiar to people who saunter in dressed grounds and trim parterres. In gardens it often remains some years without blooming, but dies in the winter after it

has flowered; for it is, or ought to be, naturally biennial. Seeds fallen in the ground from the parent mallow will keep springing up every season for a number of years: but the young plants are impatient of cold, except in maritime situations, and few survive, which may be the reason why it is so rarely seen inland. But a tolerable gardener would get over that difficulty.

At last we are arrived, and a queer-looking place it is! The town seems a *cul-de-sac*, with no thoroughfare. There is one, discoverable by the enterprising. The dull little two-storied houses, in the narrow street, stand staring full-visaged at each other, like partners in a country-dance, instead of boldly facing the wide extent of marsh, creek, sea, and sands, as you and I should place them, were we to engage one for a three-months' lodging. And, listen! A watchman's rattle! if watchmen had not been swallowed up by the police. Ah! look! it is a fish-cart from Sheringham. The "old chap," in Saxon (the "senile vendor," in Roman) English, distrusts his feeble voice to give due honour to his commodities, so, after a flourish on the rattle, "Haddocks! fresh haddocks!" is gasped forth in a faint and asthmatical cry. Oh! we are not on vulgar ground; though genteel people, dear souls! very rarely trust their precious selves to stand on the pebbly pavement over which we are passing.

"What do you want for this haddock? No. I will not give you more than threepence; if I stretch another penny, I'll have that nice 'But' into the bargain. Very well; we'll take these to B——'s, to be fried for breakfast. It will be a relief to Mrs. B., who does not expect us. Tell me; dare truly genteel people carry a couple of fish into an inn-yard between finger and thumb?"

But it is still too early to pay our respects to the Naiads, "and the nymphs who dance on the sands," though our jaunt has taken place at the best possible age of the moon. At Blakeney it is high water at six in the morning, three or four days after full moon and change. So, we can drop down to the sea and the extraordinary "meals," four or five miles distant by water, with the ebb-tide, and return with the flood in a conveniently-timed day. Before we need take boat there is time for a good walk. Almost every other path is under water, thanks to this pressing north wind, so we will follow the Marsh bank, itself a pleasing wonder.

D.

(To be continued.)

WILD BEES.

By H. W. Newman, Esq.

(Continued from vol. viii., page 422.)

APIS LAPIDARIA (RED, OR ORANGE-TAILED BEE).

THIS is another beautiful species of wild bee very common in England. It forms its nests sometimes in old walls, heaps of stones, &c., or in the earth, generally a couple of inches only from the surface. The female, or queen bee, is large, very black, and hairy, with the three last segments of the abdomen red, or deep orange; the male is smaller, quite differently marked, being nearly all yellow, except the abdomen, which is red; the worker is a smaller bee, and marked the same as the queen. This is a very common bee in some parts of England, and on the continent, but I never saw one of this species in any part of Scotland, though there is a variety of it differently marked, with nearly the same habit in every respect, most frequently found there in old walls; they go by a very vulgar name among the lower orders in the north.

Of these (Red-tailed) I have taken many nests. This is easily done, as they are mostly on or near the surface of the ground, but out of the reach of the tread of cattle. My method is to lay the nest bare in the course of the day, and after sunset, when they are all quiet, to go with a small box, and lift the whole of the nest, combs, bees, &c., all at once, and cover them up for the night. It will amply repay any one curious in these trifles to watch the exit of the workers in the morning, when the aperture is opened, and they find themselves in a new situation; the care with which they survey the entrance one by one, the slow and cautious manner in which they take their first few flights, is most

admirable. Surely no one who observes this can for a moment suppose that the bee finds its way to its hive, or nest, mechanically, without full observation.

The males of the *Apis Lapidaria* have precisely the same habits as the two last described species; these bees leave the nests a few days after they are hatched (guided much by weather), to become wanderers like their congeners. They voluntarily leave, and may be seen flying from thistle to thistle, in their lively liveries of yellow and red.

Three years ago, when at Weymouth, I met a gentleman and his little boy, who were amusing themselves at a nest, killing the workers of this species with a shoe; this was in September. I civilly asked him why he killed them; his reply was, that they had some honey. The nest they had found was at the bottom of the cliff. I caught several of the workers with my naked hand, at which they were surprised. I assured them they were quite harmless, and convinced them that it was too late in the season to find the cells full; they became converts to my opinion, and desisted from destroying them. I have opened and examined hundreds of nests at the end of August, or beginning of September, and never found any honey. They appear to consume it always before the end of the summer; probably it is not wanted after the hatching is over, for as the wild bees are dormant through the winter they require none. We walked a few hundred yards together, and I caught several of the drones from the thistles, and he observed how different they were in appearance, and wondered none had gone into the nest, nor come out while we were there. I told him the reason of this, and that they never returned.

I was at Dieppe, in Normandy, in August, 1843, where I remained a day-and-a-half, on purpose to examine the wild bees in the country near. I found the same species exactly as in England. By far the majority were the Red-tailed, and the *A. Terrestris*. I met a number of French school-boys amusing themselves in the cruel practice of killing the wild bees and extracting their honey-bags. They certainly were adepts at catching them by the back; but when they saw me take several drones in my hand, and pull them by the legs and wings, they began to think I had some magical power, and it was with difficulty I could persuade them that the drones had no stings.

There are several more species of the wild bee in Britain, varieties of those which I have described, but they have all the same habits as to the internal economy of the nest—the drones all leaving without the faculty of returning; and each of the males of all the species make a round of visits, in fine weather, in the early part of the day, to particular spots; and each species varies its flight in this respect on the ground in a manner that a little resembles the workers. I need scarcely add, that none of the honey cells of any of these bees are sealed like the hive bee. The *Apis Lapidaria* is the handsomest of its congeners.

(To be continued.)

ROOKS AND PHEASANTS.

SOME correspondents have frequently asked for advice how to establish a rookery. The reply has been, to set rooks eggs under a magpie, who happens to have built in a favourable situation for a rookery. Assuming that you could get three or four pairs of magpies to build in the same spot near together, the plan would seem plausible, for a pair of rooks will seldom stay; they join other neighbouring flocks; but three or four pairs (if thus hatched and reared) would form a little community of their own, and probably might stay. But the difficulty is to get a magpie to feed a rook. I have known the experiment tried more than once, and the magpie has always deserted the rooks, and starved them, just as the black fine feathers appeared. A magpie is a most curious and sharp-sighted bird, and is not easily imposed on. Rooks, it is true, have a great attachment to the place of their nativity. Not farther back than twenty-five years ago, I remember that a pair of rooks built annually, for several years, on a single tree, in the Royal Hotel yard, and another pair on a tree in Edmund-street, both places then being, as now, in the very centre of Birmingham, but they never staid after their young could

fly. There are two rookeries near my present residence, and one is now altogether deserted in the winter, and is used in the breeding season only, I presume for the sake of the old nests, and by those birds who were bred there.

I have tried to rear young carrion-birds from their unfledged state, and they generally have lost the use of their legs when about fledged. I attribute it to a mistake in feeding, or in the food itself. If I wished to try to raise a rookery, and had a very suitable wood of trees, for they must be high, and a good many of them together, I would get some rook's-eggs, and set them under a bantam or light hen, and would try to rear the young by hand, in a place made amongst the trees, and I would turn them out as I would young pheasants or partridges, when they just began to peck; or the nests themselves might be robbed of their young when hatched, but you must recollect that you can never tame any bird or animal half so well after it has once opened its eyes upon, or been fed by its own parent, as you can by never letting it know any fostering hand besides your own; but the experiment of making a rookery is a very doubtful one.

One word to sportsmen on rearing pheasants, the result of experience. Do not turn up your tame or caged hens in your woods in the spring, to be eaten by foxes and vermin, and avoid putting a tame or caged cock pheasant with your hens to spoil their eggs through incompetency. Crop the hens wings, and put them in a wired place, open at the top, where the wild cock pheasants can have access to them. Then sit off the eggs under a hen, and rear in the usual way.

A WORCESTERSHIRE MAN.

TO CORRESPONDENTS.

** We request that no one will write to the departmental writers of **THE COTTAGE GARDENER**. It gives them unjustifiable trouble and expense. All communications should be addressed "To the Editor of the Cottage Gardener, 2, Amen Corner, Paternoster Row, London."

PRESERVING BALSAMS BY CUTTINGS (J. B.).—There is nothing new in this. The difficulty is to keep the cuttings healthy over the winter in a cool greenhouse. Place them at the warmest end, and if even then the cold should seem too much for them, put the glass over them, under which you struck them. Give little water, but keep them from flagging. A little labour, and you will be rewarded with compact bulbs, very full of flowers.

CALCEOLARIA SEED (A Subscriber).—Your greenhouse would have been quite sufficient for this. No stove heat is required. September is the best month in the year to sow, &c., but as October will be progressing before you see this, we would almost advise you to wait until February, then proceed as follows:—Fill a pot or pots half full with drainage, then with sweet soil, somewhat rough, to within three-quarters-of-an-inch of the top, then fill with half-an-inch more of fine-sifted soil—if a little peat in it all the better—press it down, and then set the pot over head, for ten minutes, in a pail of water; take it out and let it drain for at least twenty-four hours; then place the smallest quantity of fine sandy soil on the surface, press it gently and evenly down, and on this sow the seeds very thinly; then scatter over them a film of dry fine sand, and press again. Put a square of glass over the pot; on this glass place a little damp moss, and set it in a shady part of the greenhouse; remove the moss as soon as the plants appear, and give them a high position, allowing the glass to remain until the plants are some size. They are impatient of water until they are pricked off; and to avoid watering, you will succeed better by plunging the pot into a larger one, and filling the space between with moss, which you can keep moist.

GESNERA ZEBRINA (T. M. W.).—This being in bud, and looking healthy, will no doubt bloom, if you give it a temperature from 56° to 70°. We frequently have it in a glass case in summer, a greenhouse in autumn, and a plant stove the most of the winter.

FUCHSIAS GROWN IN POTS ON A SINGLE STEM (E. C. S.).—You have not told us your advantages. Keep them anywhere during the winter, free from frost, and just not dry, but moist rather than wet. Then cut down in spring, if you want a bush, or merely cut-in the side-shoots, and shorten the top one if you wish a Pyramid from a single stem, and repeat when the shoots have broken a couple of inches, and grow slowly, if you want a robust habit. You may prune in a month, if you like, but we should prefer spring for getting some nice cuttings, if you wanted them. See some hints by Mr. Fish, to-day.

NIGHT-BLOWING CEREUS (Legtonensis).—This is almost as hardy as the rest of the Cacti that will stand well in a greenhouse in winter, when kept dry, and in a state of rest. In such circumstances, it would require the warmth of summer to open its blossom. As to whether *Nematanthus longipes*, *Eschynanthus javanicus*, and *Bignonia insignis*, are suitable stove plants for exhibition, we must reply that we do not know the last, and are not sure we know the second; but all the *Eschynanthuses* are good when well grown. The *Nematanthus* we have had

in bloom for long periods, but scarcely profuse enough to be fit for an exhibition-table, but we did not give it much attention. The long flower-stalks give it a very singular appearance, when seen suspended from the branch.

TWENTY STOVE PLANTS SUITABLE FOR EXHIBITION (Ibid).—The following we think will suit you:—*Allamanda cathartica*, *Allamanda Schottii*, *Æschynanthus speciosus*, *Æ. longiflorus*, *Æ. miniatus*, *Aphelandra aurantiaca*, *Begonia cinnaburina*, *B. fuchsoides*, *Cassia corymbosa*, *Chirita Moonii*, *Clerodendron fallax*, *C. splendens*, *C. Kämpferii*, *Dipladenia crassinoda*, *Franciscea confertifolia*, *F. latifolia*, *Gardenia Stanleyana*, *G. Devoniana*, *G. Fortuniana*, *Glozinia grandis*, *Hoya Bella*, *Ixora coccinea superba*, *I. javanica*, *I. grandiflora*, *Medinilla speciosa*, *Rondeletia speciosa major*, *Stephanotis floribunda*. Take only one of a genus if it suits you, and add, *Gesneras*, *Glotinias*, *Achimenes*, and *Begonias*, as many as you please.

PIT FOR FORCING, PROPAGATING, &c. (B. A.).—We might make an instructive article upon the subject of your pit, ten feet wide, twenty-five feet long, and divided into two divisions, but we cannot answer your questions at large, so as to be useful to others, without a drawing. Let the following for the present suffice. 1 and 2. If your roof at the apex is either a foot higher, or the walls a foot lower, the angle of inclination will be better. 3. Depth of earth two feet. 4. Size of ventilators in front and back walls opposite each light, twelve inches by six inches, but at the front and back sashes more. These, though useful, will not be *absolutely* necessary, but the one opening into the hot-air chamber, and the other over the pipes at back, air may be safely admitted, when it would not be proper to move the sashes. 5, 6. Four-inch pipes will not be too large to heat the tank, though three-inch would do. These cemented troughs *are* useful, but we have no difficulty in getting moisture, by placing open rubble over pipes, and throwing in water when necessary. 7. We would use three, instead of two-inch pipes, for top dry heat, as the water circulates languidly in two-inch pipes, and if we had them at all, we would rather have them in front, or round the house, instead of at the back, as this of itself would preclude your placing according to question 9. Peach-trees against the back-wall, which, however, would not answer so well in such circumstances as vines and cucumbers. We do not see how you are to have additional dry heat from your tile drain 8, in front, as that communicates with the open chamber over the gutter, as well as the opening in the side, 7, to admit moist air. Now, by sinking your floor, for supporting the bed, some twelve or eighteen inches nearer the gutter, and we suppose this floor to be of slate, or some analogous substance, you might still have slides in the side for moist air at will, and then shafts all round communicating with the flooring would give you dry heat at will, besides enabling you to have plenty of rough material, such as brickbats, charcoal, &c., below the bed of earth. With such contrivance, unless you wanted to force plants and melons very early, the two four-inch pipes would be sufficient, especially with a canvass covering in severe weather. 8. The boilers will be nothing too large. 10. Glass, 16-oz. will not be too strong for panes forty inches by twelve inches; but why have them so long; just think of having such a thing as a crash, and the expense and trouble of replacing them. On the whole, we do not approve of your arrangement. Your pit over the gutter or tank is six feet wide, abutting on the front-wall, leaving four feet behind, you must open your front sashes to attend to the management of whatever you have. Why not place the pit in the centre, five feet wide, with two-and-a-half feet wide paths, back and front. You would thus have the whole place at command, and find yourself quite at home in the worst day, as well as the finest. Before building, examine a most economical arrangement of a house, given by Mr. Fish, at page 337, of our second volume. That house still answers admirably, the gardener does little wonders with it. If, however, you are wedded to your present arrangement, you might have a pit eighteen inches wide, and two feet deep, placed over your pipes at the back-wall, and there you may grow vines or cucumbers, to cover the wall, and hang from the hipped roof.

HOLLYHOCKS.—A *Constant Subscriber* recommends *Queen of England* (Chater and Son); delicate pink; very fine; beautiful. *Aurantia* (Rivers); salmon and orange; beautiful. *Obscura Suberba* (Chater and Son); silvery-shaded puce; a decided improvement upon *Obscura*. *Beauty of Haverhill* (Chater and Son); silvery-lilac; beautifully veined. *Napoleon* (Powis); slate, edged with light; fine. *Bella Donna* (Woods); white; one of the best out. *Meteor* (Bircham); crimson; fine. *No. blissima* (Chater and Son); rosy-red; mottled and veined; fine. *Rosy Queen* (Chater); rosy-blush. *Lady Cullum* (Chater and Son); rosy-crimson, glowing as if shot with purple; fine. *Susannah*; creamy-white; very fine. *Abriote* (Chater and Son); colour apricot; fine shape; large size; a noble flower. *Surprise* (Chater and Son); rosy-crimson; fine. *Journ of Arc* (Parsons); silvery-blush; very fine. *Yellow Model*, or, rather, *Primrose Model* (Bircham); this is very fine.

PROLIFIC DUCKS.—Mr. Edwards, Station-Master at the Jynderhurst-Road Railway Station, Hants, has a couple of ducks of the pure white Aylesbury breed, which have laid this season the prodigious number of 261 eggs. One of them laid in daily succession 146 eggs; and she is now running about with a brood of 12 young ones. The other laid 115 altogether; and she has now her second brood, having brought up her first brood of 13 early in the summer.

NEW SYSTEM OF SWARM-MANAGEMENT.—A *Country Curate* says, "I have been all along puzzled to account for the rather peculiar failure of "B. B.'s" trial of the new plan; but at last he has furnished us with some clue to the discovery of the probable cause. He had not learnt his lesson with sufficient care, when he applied himself to give my plan a trial. I have never myself stopped up a hive "from twenty-four to thirty-six hours," (from which a swarm had issued naturally) "as soon as the swarms had left the hives;" nor do I remember any where to have recommended such a treatment! I have said, indeed, that it may be well to stop up such a hive for a few hours on removing it to a fresh stand, but I have generally left my old hives so treated quite open from the first! To stop them up, however, for such a length of time, so full too of bees as they still usually are, after the issue of a natural swarm, I should at once have deemed a most mistaken method of proceeding. It is far otherwise in the case of a stock from which an artificial swarm

has been taken. In this instance there are usually but a *very small* number of bees left in the hive, the drones are mostly all in company with the swarm, and there is *no royal brood* to suffer. But in a stock from which a natural swarm has issued, many (perhaps most) of the drones remain. This, from the nature of the case, we might expect; not only so, there are usually many bees left, and above all, there are young royal queens, perhaps all in a state, and of an age requiring the most assiduous attention. Now what follows in both instances where the old stocks are shut up for so long a space? In the one instance, where the swarm was forced out, the temperature, owing to the paucity of bees, can seldom rise, from the necessary agitation within, to any very inconvenient height; at all events there is *no royal brood* to suffer. In the other case, however, when the swarm issued naturally, the heat from the large population might be expected to rise to a very dangerous height, and it would be almost sure to follow that the royal bees still in the grub state would suffer from that, or from neglect. This, to me, appears to afford quite a sufficient explanation of "B. B.'s" failure. It is the *management*, not the *system*, that is at fault here. But, moreover, I should very much question the policy of "running honey" out of the old hives, unless in a *very* thriving condition. I have never advised it. No doubt, too, the failure of "B. B." must be put down in part to the *very bad* season we had almost everywhere in June. Few mid-June swarms or their parent stocks will be found to have done anything this year. I shall be obliged to "B. B." to give us his opinion of the value of the above remarks. I cannot make out "H. S. N.'s" observations. He is not particular enough in narrating his facts. For instance, is he speaking of the stock or the swarm when he says, "I could not by any means induce them to work in the super?" "No. 3 natural swarm" could not possibly have come out of the stock, in whose place it was put, else there would have been no such fighting as he speaks of. The "fighting," which he says he has seen "more or less at all the swarms that have been put where the stock formerly stood," must have been only in appearance. I have never observed it. It is a *bad* sign to see drones in September, but worse in October. If any are seen now, fumigate and plunder.

VEGETABLE MARROW, &c. (Rosasolis).—It is Vegetable Marrow, and not *Mallow*; and is a kind of gourd. *Ixias* and *Sparaxis* are propagated both by seeds and by offset bulbs; and both ought now to be potted or sown in pots, in good turfy peat, with a little sand, and placed in a cold pit, or on a shelf in a greenhouse; the soil to be kept moderately moist all through the winter, and free ventilation whenever the weather is mild.

BIGNONIA RADICANS (Ibid).—It requires to be close pruned like a grape vine; and, after it comes to a flowering age and strength, it is generally a free bloomer on a south wall, or inside a cool greenhouse in less favourable situations. Can any of our Irish readers tell him what is the right name of a plant there called *Melidore*?

FUCHSIAS AND GERANIUMS (R. E. S.).—The Fuchsias will stand out with a slight protection from frost, and all your old Geraniums must be taken up, their green tops cut off, and the hard bottom parts and roots, after being partially dried, may be packed in a box or hamper with dry fern or hay, and put away from the frost like so many potatoes; but look at them from time to time, to see that they do not turn mouldy. Cuttings will do no good now.

LIST OF BULBS (S. S. S.).—We shall begin to analyse your bulb list immediately, and we hope between us to be of great service to many of our readers. Accept our best thanks for your share of the undertaking.

FLOWER-GARDEN PLAN (J. H. N.).—Your plan will be engraved as an example of a very useful and easy way of managing such a space. As to your *Allamanda*, with seven upright shoots, two feet high, cut four of the weakest shoots down to within two joints of the old wood, and the other three cut to one-half their length; this pruning to be done in March, as soon as you perceive the least appearance of growth; do not give the plant much water all the winter. A good gardener would prune so weak a plant of *Allamanda* at the end of this month; keep it nearly dry all the winter, and "set it to work" in a hot-bed by the end of February; shake away the soil from the roots on the first move of growth, trim the roots, and put it in a smaller pot, force it vigorously for three months, and give it two, if not three, shifts before the end of June, and would have it in bloom nearly by that time; that way would be most dangerous to a less experienced person.

GARDEN NEAR GLASGOW.—J. C. says: "In our garden on a south wall we have *Ceanothus puniceus* (the largest I have ever seen, and a perfect picture in April and May), *Acacia armata*, *Aloysia citriodora*, and a great variety of Tea and other Roses, all of which stand the winter without any protection. Fuchsias grow with us to an immense size. As I have noticed several inquiries in THE COTTAGE GARDENER regarding the *Noisette Rose Solfaterre*, I may mention that we have a plant covering a large part of the front of our house (I say our, for it is my father's, but my brother and I are the gardeners!), which has been in constant flower since the beginning of May last, and still showing buds; it was not pruned at all this spring. We have also had some very fine flowers on *Cloth of Gold*, budded on the Crimson Boursault. All the above are growing in a well-drained border, composed of peat, loam, and sea-sand, the former predominating. In the greenhouse, we intend growing Tea and other Roses for spring and late autumn flowering, and we purpose planting them in a border formed all round the house, instead of growing them in pots, as our time being limited would not admit of the constant attention necessary, as to waterings, &c., were they grown in the latter way. Although Roses are principally what we intend growing, yet we purpose having a selection of other suitable things, and I shall be glad if you would furnish me with a list of such things (including climbers), as you think would be likely to stand the winter without fire-heat; and here I fancy I hear you say—But why not have a flue or brick stove, in case of severe frosts? Well, because as we are residents in town during the winter months, and leave no one who understands the matter to attend to the fire, we thought we should be less likely to have our hearts broken by trusting to Jack Frost, than by leaving fire-heat in the hands of a bungler. Don't you agree with us?" [Yes; certainly.]

GRAPE FOR A COLD GREENHOUSE (J. C.).—The *Royal Muscadine* is the best white, and the *Hambro'* the best black, for such a house as

yours, on the coast of Loch Long, beyond Glasgow. If you plant these vines, you must give up all ideas of other climbers for this house, except, perhaps, *Bigonia* or *Tecoma radicans grandiflora*, which requires the very same treatment in every respect as these hardy grape vines. We know Glasgow Green, and both sides of the Clyde below it; also some of the "bunglers," and best men in these parts; and, as very little can be done on the coast until you go down next May, you will excuse us for not giving you a list of suitable plants for summer culture until we consider "a wee." Some of our London readers, who know as much of Loch Long as of Timbuctoo, will be astonished to read your account of the gardening on that part of the west coast of Scotland. It will be no surprise here, however, to hear of the sons and daughters of wealthy fathers being so much in their garden.

ROSES ON TURF (E. S. F.).—Standard roses will not do so well in groups when the roots are covered with grass as when they have an open circle or bed. A group of standard roses on grass, by the way, is one of the most frightful things that you could devise or think of for a flower-garden; something as if Her Majesty, while at Balmoral, had all the ladies of her household dressed in kilts of the royal tartan. Rather have them planted in this wise—three tall standards in the centre; five half-standards round them; and ten or a dozen strong dwarfs outside of all. These dwarfs should be worked plants on six-inch stems, and the grass might be laid quite close to the stems of the outside row; then, from May to November, who would know but your roses were "on grass?" All the plants or kinds of roses in a group of this kind, should be of equal strength, so as to keep up the uniformity of the whole.

FLOWER-GARDEN PLANS (Ignotus and Others).—One will appear this month, and will be followed by others in a monthly series.

HARDY FERNS (Tom Pouce).—As you intend transplanting native ferns from your own neighbourhood into your rock-work, which you are now constructing, you may begin at once, and go on with them, to the end of next March, as the weather allows. The smaller kinds you will easily remove, as their roots run near the surface; but the roots of the great, strong-growing ferns run very deep, and they must be trenced out to do much good; but if so treated, they want no balls with them. We have known scores and scores of pounds wasted in removing thick, square pieces of turf, or balls, from native fern brakes to "inoculate" parks and rough pieces in pleasure grounds, such balls carrying only the buds and leaving the roots behind. When a piece of fern land is broken-up for cultivation, the farmer will tell you that the roots of ferns are as bad to get rid of as the roots of docks, and this ought to teach us gardeners that the large, common ferns come from pieces of the roots, and so we ought to know better than plant only buds and balls.

MOSS ROSES (An Old Raven).—You must take them all up early next month, trench the ground two spits deep, mixing a good quantity of rotten dung with it if the roots are long, black, and fibreless, as we expect they are, cut them back one-half, and cut in the branches quite close to the old wood, and if the old wood is long, cut one-half of the shoots to near the bottom; then replant them, and put some littery dung on the surface of the ground to mulch them, and next May, when you see the leaves coming out, begin to water them freely, and let them have some weekly to the end of July. If they come up strong, give liquid manure occasionally.

FLOWER GARDEN PLAN (W. T.).—The planting is unexceptionable, and as your *Heliotropes* agree with the *Ageratums*, there is no objection in the least against the mixture, and the centre bed is just the right place for them; but this is the only bed in your garden that is fit to be seen; the four flanking it are *dumpy*, the rest quite frightful. We have not seen the work you allude to.

COCHINS v. SPANISH.—Q. in a Corner says: "I like the spirit in which 'Gallus' writes; agree with him in general as to the excellence of Dorkings, but dissent from his conclusion *in toto*. Having kept almost every variety of fancy poultry during the last thirty years, and paid great attention to their consumption of food, always feeding them *myself*, I have arrived at the conclusion, that if there is any difference in proportion to size, Malays are the *greatest* eaters; that Cochins do not eat more than Spanish or Dorkings, in *proportion* to size; that they are *easily* satisfied, and *often* leave part of their allotted food; and, in opposition to Mr. Bailey, no mean authority, I find they fatten *rapidly*, and that the short-legged variety lay on much flesh on breast and wings. As to their excellence as a table fowl, much, I think, remains to be proved, as the price has hitherto proved a bar to a fair trial on a large scale. Allow me to say, that to sit down to a poultry-dinner, knowing that they are Cochins, and having a preconceived notion that they are *not very good*, is *not a fair trial*. Will 'Gallus' or Mr. Bailey, who so kindly comes to his rescue, allow themselves to be blindfolded, and in that state sit down to table, having slices of poultry set before them, and then say whether it is Spanish, Dorking, or Cochin, *from favour only*? If so, I will confess myself satisfied, but not till then. Is there not in the name of Dorking a charm that would give relish to *any* fowl sold under that name? The only difference I could ever discover, was a flavour in some Cochins approaching that of game, which can hardly be an objection. I know of a case where a very knowing gent sat down to dine off a large Shanghai cockerel, dressed as a Turkey poul, and yet could not discover the cheat. So much for *flavour*. This, however, would go to prove that in this breed there is a little difference in flavour; but I write for information, not victory. As to *productiveness*, there is certainly no comparison between them and Spanish, as far as my experience goes; none in the ease with which chicks are reared,—the Spanish being proverbially difficult to rear. The opinion of some of the oldest and best fanciers has been sought, and it fully coincides with the above. One, when reading the article about the excellence of Spanish fowls as *layers*, laughed outright, and said that they were anything but good, when compared with Cochins."

RED SPIDER (A Twelve-month Subscriber).—We take it that by "Garden Spider," you mean *Red Spider*, and if so, tobacco-smoke will not kill or drive him away; neither will your other remedy,—sulphuring the house,—affect the *Dry White Scaly*, or the *Soft Mealy Bug*, if they are included in your "several other insects." Nevertheless, it is a very

good plan to turn out all plants once or twice a-year from a greenhouse, or from pits, and burn sulphur in those structures, and to keep the doors and ventilators closed for a day or two afterwards. Then, after a few hour's free admission of fresh air, the house or pit is safe enough for any plant. If you use grass as you propose, the expense of keeping it in order will be double what it is now, but your place would look much better. Circles, not more than four feet through, and ovals, eight or nine feet long, are the only shapes suitable for such strips of ground.

EDGING PLANT (Lover of Flowers).—We do not know "a hardy herbaceous perennial that will be in bloom from the 1st of June to the end of September, and not to have pink flowers."

CHINA IRIS (W. G. N.).—It is not at all a fit plant for pots, unless you were an expert gardener. Place it under a west wall, in rich light soil, and it will take care of itself, and blossom there; it is hardy enough, and wants no protection.

PEAT (Y. Z.).—How can we tell you what to put it to, unless we knew what plants you cultivate, and the nature of your soil? It is not used for *Geraniums*; but is especially required for *Heaths* and *American plants*. Keep it under cover. *Crocuses* do not require manure, unless the ground be poor, but to be grown in a moderately rich, well-drained, light soil.

PHLOMIS FLOCCOSA (Subscriber).—This is a half-hardy evergreen, and is so described in *The Cottage Gardeners' Dictionary*, if you read the description there given. To avoid numerous headings, all the half-hardy species are put together. You are there told its average height, colour of flowers, time of their being open, native country, and date of introduction. We have little more to add to such history. It is called *floccosa* on account of its woolly branches. It flowers usually from July to October. There is a drawing of it in the *Botanical Register*, t. 1300.

EQUATION OF TIME (Cockerham).—We believe it is right; we are indebted for it to the *Gardeners' Almanack*, and for that the Stationers' Company employ an astronomical authority.

ROSES PEGGED DOWN (A Recent Subscriber).—We have set our face against the plan of pegging down Roses altogether, for reasons long since explained; therefore, we said nothing about it in *The Cottage Gardeners' Dictionary*. Super-phosphate of lime is good for Roses, no doubt, but good old cow-dung, we think, is far better for them; but try the two, and let us hear the result.

POTATOES IN COLD, WET CLAY (M. R. P.).—Do not plant your potatoes in such a soil until February. Until then keep them buried in layers alternating with coal ashes, or sand, in a cool, dry shed. When you plant, do so in beds about four feet wide, with deep alleys between to drain them. Lime, bricklayers' rubbish, coal ashes, and tan, would be good applications to such a soil. We should plant Ash-leaved Kidneys.

SAIL-CLOTH FOR FRUIT-TREE SHELTERING (A. Z., W—n).—You may obtain this of Messrs. T. and D. Henry, 44, Mark Lane, London.

PLANTING POTATOES (K. H., Dublin).—We regret that the gentleman who instituted the experiments is dead, but we are promised a report of their results.

LIVER-COMPLAINT IN RABBITS.—In number 205, Sept. 2nd., "Amicus" asks if any reader knows a cure for liver-complaint in rabbits? I believe it to be caused by damp, and want of fresh air, also by moist or unwholesome food. I have had rabbits killed by it, that have thriven well in an open grass-plot, till a wet week came on. I think it may be known by the rough and lean appearance of the animal, and I have cured it by keeping them clean and dry, and giving them salt in their dry food. I do not think that the rabbits often grow out so fine afterwards if they do it bad.—B. P. B.

COCHINS NOT FATTING.—I must beg to differ from "Gallus," and Mr. Bailey, respecting Cochin-Chinas not fattening. My young fowls have always been exceedingly fat and delicious eating, and have been pronounced excellent by all that partook of them. Mine, however, are not, I think, the largest sort, more like what "An Old Subscriber" calls the Lovell Cochin-Chinas. So the varieties may differ in their gastronomic qualities.—B. P. B.

PICKLED SAMPHIRE (E. S. D.).—Well sprinkle your fresh-gathered samphire with salt. Cover it with spring water, and let it stand twenty-four hours; then put it into a brass pan, with another handful of salt, and cover it well with vinegar. Cover the pan close, and set it over a slow fire until green and crisp, at which moment take it off, for if allowed to get soft it will be spoiled. When cold, tie over your jar both a bladder and a leather. Samphire may also, we believe, be kept all the year in a strong brine of salt and water, throwing it into vinegar just before you wish to use it.

NAMES OF PEARS (Mr. Watson).—No. 1. Marie Louise. No. 2. Beurré d'Aremberg. No. 3. Marie Louise. No. 5. Easter Beurré, small, bad specimen. No. 8. Napoleon, ditto. No. 13. Nelis d'Hiver. No. 14. Glout Morceau. No. 20. Duchesse d'Angoulême. No. 21. Nelis d'Hiver.

POTATOES (E. O.).—We should grow no other Kidney Potato than the *Ash-leaved*; and no other round Whites, than *Rylott's Flour Ball*, *Fox's Early Delight*, and *Hoptown Early*.

NAMES OF PLANTS (Tyro).—*Escallonia montevidensis*, or *floribunda*, for we believe the two species are identical. It grows without shelter in the Dean of Winchester's garden, at Bishopstoke, Hants. (*Rev. R. M. E.*)—The plant found by your botanical friend in a field near Cloyne, in Ireland, is not a *Verbascum*, but *Celia Cretica*, a half-hardy biennial native of Crete, but growing like a weed in the garden of the Warden of Winchester College. It must have escaped from some garden.

LONDON: Printed by HARRY WOOLDRIDGE, Winchester High-street, in the Parish of Saint Mary Kalendar; and Published by WILLIAM SOMERVILLE ORR, at the Office, No. 2, Amen Corner, in the Parish of Christ Church, City of London.—October 21st, 1852.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last twenty-five years, the average highest and lowest temperatures of these days are 54° and 39.3° respectively. The greatest heat, 67°, occurred on the 29th in 1833; and the lowest cold, 20°, on the 3rd in 1845. During the period 90 days were fine, and on 85 rain fell.

BRITISH WILD FLOWERS.

BERBERIDS.—BERBERIDACEÆ.

(Continued from page 22.)

EPIMEDIUM. BARRENWORT.

GENERIC CHARACTER.—*Calyx* below the fruit, of four small, egg-shaped, concave, spreading, deciduous leaves. *Corolla* of four egg-shaped, equal, concave, spreading petals, opposite to the calyx. *Nectaries* four, one lying upon each petal, and nearly as long, pouch-like, blunt, equal, attached underneath to the *receptacle*, by one side of the orifice. *Stamens* with filaments, awl-shaped, erect, close to the style. *Anthers* of two oblong-oval, parallel cells, attached longitudinally to the inner side of the *filament*, below its summit, each cell opening by a valve, which bursts from the bottom and rolls back. *Germen* elliptic-oblong, with a furrow at the back. *Style* oblique, roundish, the length of the *stamens*. *Stigma* simple. *Pod* oblong, pointed, of one cell and two valves. *Seeds* numerous, unilateral, oblong.

EPIMEDIUM ALPINUM: Alpine Barrenwort.

Description.—It is a perennial. *Root*, creeping, slender, and thread-shaped, by which it increases rapidly. *Stems* about ten inches high, solitary, stiff, smooth, cylindrical, semi-transparent, three-branched at top, near the root scaly. *Leaves*; there are no leaves springing direct from the roots, but each branch bears one most elegant and delicate leaf, on a longish stalk, either once or twice subdivided into three leaflets. *Leaflets* hanging down perpendicularly, heart-shaped, ending in a point, about an inch-and-a-half long, but enlarging after the flowering is over, very veiny, saw-edged, and each tooth ended with a hair, pale-green above

and greyish beneath. From the point where the stalks of the subdivisions of the leaf join the footstalk common to them all, springs the flower-stalk, which bears a cluster of flowers about four inches long, the flowers scattered upon it widely apart, on three or four branchlets, each branchlet usually two-flowered. *Petals* four, dark-red, and contrasting strongly with the four large pale-lemon-coloured *nectaries*, which are full of honey, and very peculiar. *Stamens* short. *Anthers* with a taper point, and two lid-like valves. *Stigma* yellowish, encircled at the bottom by a red band. *Seed-vessel* a one-celled pod, with many seeds.

Places where found.—In thickets in some parts of Yorkshire and Cumberland; on Skiddaw; and near Glasgow and Edinburgh. Very rare.

Time of flowering.—May.

History.—This plant is included in the Tetrandria monogynia class and order of the Linnæan system. It is of such rare occurrence, and has only so comparatively recently been discovered in Britain, that many botanists doubt whether it is really a native of our islands. Gerarde, in his "Herbal," published in 1597, says, "This rare and strange plant was sent to me from the French king's herbarist, Robinus, dwelling in Paris, at the sign of the Black Head, in the street called *Du bout du Monde*, in English, The end of the World. This herb I planted in my garden, and in the beginning of May it came forth of the ground. Its seed came not to ripeness in my garden, by reason that it was dried away with the extreme and unaccustomed heat of the sun, which happened in the year 1590, since which time, from year to year, it bringeth seed to perfection." Johnson, in his edition of Gerarde's Herbal, published in 1636, says, "It groweth in the garden of my friend, Mr. John Milton, in Old Street, and some other gardens about town." This "Mr. John Milton" was the author of "Paradise Lost." Parkinson, in 1640, gives a very accurate description of the plant, but only mentions the mountain districts of Italy as its native place, and Ray, in 1688, says no more than, "I observed it on the Alps, not far from the town of Ponteba." Even as late as 1807, Dr. Martyn writes, that "Mr. Miller affirms that he received some plants of it which were found growing naturally in a wood in the north of England, but he was probably misinformed." Mr. Miller may, therefore, be considered its first recogniser as a native plant. It was certainly found by the Rev. T. Gisborne, in 1787, "in a very wild part of Cumberland called Carrock Fell," and by Mr. Robson, on Skiddaw, in 1795. Johnson seems to have named it *Barrenwort*, "not because that Dioscorides says it is barren both of flowers and seeds, but because, as some authors affirm, being drunk, it is an enemy to conception."—(Smith. Lindley. Martyn. Withering.)

A CORRESPONDENT (W. H. O.) writes to us as follows:—"The advantages of double-glazing are numerous, and among them are included the saving of mats, the saving of the time in covering and uncovering, the gradual return of light to the plants in the morning, the gradual withdrawal of the light at night, and the longer time the plants would have the light, *i.e.*, from earliest dawn to the latest daylight. Moreover, I think that the second glass may have the effect of correcting any fault

in the refraction of the upper glass, and thus prevent burning. I have six small lights, three feet by four feet, double-glazed, and on Saturday last there occurred a rather sharp frost; all my glasses were covered with white frost, with the exception of two places which exactly corresponded to panes which had been broken in the under glazing."

The two places on the outer glass were kept free from white frost by the rush of warm air against them

through the broken panes beneath, and affords strong evidence of the check to the escape of heat which a second glass affords. Let it not be supposed, however, that there ought to be any opening in the inner glass for the purpose of admitting warm air from the bed between the two glazings. So far is this from being desirable, that the panes of glass, both in the lower and upper glazing, should be puttied even between the laps, in order that they may be rendered as nearly as possible air-tight.

The philosophy of double-glazing shows that its power to protect from frost depends upon that tightness, for it is only air confined, or kept quiet, that is a bad conductor of heat, and air in motion carries off heat very rapidly. The most intense cold in calm weather was not a cause of suffering to Captain Parry's men when properly clothed at the North Pole, but the same degree of cold, when the wind was high, was not endurable, although the thermometer showed there was no lower degree of temperature—the air in motion carried off the heat faster. The same principle is in operation when a wet finger is held up to detect which way a current of air is passing, by its rendering one side of the finger colder than the other.

It is on the known fact that air is a non-conductor of heat, that double windows are employed in Russia to exclude the cold, and in the West Indies to exclude the heat. This is no anomaly, for to exclude cold is only another mode of expressing what is intended when we speak of keeping in the heat. In Russia they have to keep the room's heat from escaping into the air, and in the West Indies they have to keep the air's heat from getting into the rooms.

In double-glazing our garden frames, we have the same object in view as they have in Russia; and if the frames had double boards, or the pits double walls, as some ice-houses have, the cold could be excluded, so as to protect many more plants than at present we are able to carry through the winter without the aid of artificial heat.

Another advantage attendant upon double-glazing, besides those mentioned by our correspondent, is the prevention of "drip" within the frame, pit, or house. This is occasioned by the warm air, which contains moisture in proportion to its warmth, coming in contact with the cold glass, and there letting drop all the moisture it is not capable of holding at the lower temperature to which it was cooled by the glass. When the difference between the temperature of the glass and that of the air is great, the moisture is deposited, or let drop, in such quantity on the glass, that the moisture trickles down and forms "the drip." Now, double-glazing would prevent there ever being so great a difference between the temperature of the inner glass and the temperature of the air in the house, as to cause such a sufficient deposition of moisture as to form "the drip."

COVENT GARDEN.

SOME of our readers will be disposed to doubt the correctness of our observation, and the authority of these "city articles" of ours, when they see in Covent Garden fruits purporting to be varieties which we said two or three weeks ago were over for the season. But this is no uncommon occurrence; such modes of imposition having been practised ever since we have known the market, and, for ought we know, one which boasts of as great antiquity as that which we exposed last week in reference to the Elder berries. It may be laid down as a general rule, that whatever kind of fruit you ask for, you can have it. Jargonelles at Christmas, or even at Easter; Brown Beurés all the year round; Ribston Pippins *passim*; and "fine Burgamys," are among the leading articles with these very accommodating traders. Our readers must, therefore, be on their guard how they receive the assurances, and place too much confidence in these individuals. It would be wrong, however, to say that there is no confidence to be placed in any of the fruiterers, for we know that there are some of them who are of the highest respectability and integrity, and who would scorn to be concerned in such practices.

FRUIT.—There is still a continued abundant supply of APPLES, and at a somewhat advanced price; some sorts having made as much as 7s. 6d. per bushel. The general belief is, that Apples are a very short crop, and will, before the season is much farther advanced, be less plentiful than they now are. The sorts which have been most plentiful during the week are—*Ribston Pippins*, *Blenheim Orange*, a fine apple, but, generally speaking, not so large this season as we have observed it. The *Nonesuch*, *Winter Strawberry*, and *Beauty of Kent*, are among the leading sorts, as well as a few parcels of *Emperor Alexander*. In our report of the week before last, our printer's devil, who, like all other devils, is always up to some mischief, made us say there were Golden and Winter Pearmain's in that week's supply, whereas, in "the copy," we only mentioned the Golden Winter Pearmain. The Winter Pearmain's, so far from being in the market, are hardly gathered yet. This *Golden Winter Pearmain* is by some called "King of the Pippins"—a title given to it by a London nurseryman, who, either for the purpose of deceiving his customers, or with the view of retaining the sale in his own hands, applied to it this high-sounding name. Of PEARS there has been an abundance, particularly of *Marie Louise*, which has now become so common as to be met with on almost every fruit-stall in the streets. The *Bishop's Thumb* is also very plentiful, and we observed one or two parcels of the very old-fashioned *Messire Jeane*, which is one of those obsolete French pears that have been displaced by the new Flemish varieties. In the centre arcade were some of the finest *Duchesse d'Angoulêmes* we have ever seen; more like large pear-shaped gourds than pears; they were received from Guernsey. The *Catillac*, which is a stewing pear, has also appeared during the week, but, fine as they looked, there are some others which we would very much prefer to it for that purpose. The great objection to the *Catillac*

is its grittiness, and, however well-grown they may be, this is a characteristic which they invariably possess. If any of our readers are desirous of possessing an excellent stewing or baking pear, there are none which will give them greater satisfaction than *Bellissime d'Hiver*, *Flemish Bon Chrétien*, and *Vicar of Wakefield*; of the latter there have been some very fine specimens exhibited in the market.

VEGETABLES.—These continue plentiful. **CABBAGES** do not vary in price from last quotations, ranging from 6d. to 1s. per dozen. **CAULIFLOWERS** furnish a good supply, and some are of excellent quality, which make 2s. 6d. per dozen, but inferior examples are as low as 6d. **BRUSSELS SPROUTS** about 1s. 6d. per half-sieve. **COLEWORTS**, 1s. to 2s. per dozen bunches. **CARROTS**, of which there are some very fine samples of the *Long Surrey* and *Altringham*, make from 2s. 6d. to 5s. per dozen bunches. **TURNIPS**, 1s. to 1s. 6d. per dozen bunches. **ONIONS** are plentiful and fine, chiefly of the *White Spanish*, or, as it is sometimes called, *Reading* sort; they make from 2d. to 4d. per bunch. **SCARLET RUNNERS** are freely sold at 2s. per half-sieve. **ENDIVE** is very fine, large, and well-blanching, of the *Green Curled* variety, and was selling at from 1s. to 1s. 6d. per score. **CUCUMBERS** continue plentiful, at from 2d. to 6d. and 9d. each. **POTATOES** are rising in price. Fine *Regents* cannot be had, well picked and free from disease, under £7 per ton.

PLANTS AND FLOWERS.—The near approach of winter has banished flowers in pots, and their place is taken by grim, cemetrean-looking "greens," wherewith the Londoners may, for the next six months, adorn their halls and balconies. Of these we may enumerate nice bushy plants of *Laurustinus*, *Aucuba*, *Siberian* and *Chinese Arbor vitæ*, *Cotoneaster microphylla* and *buxifolia*, adorned with red berries, *Exmouth magnolia*, and *Tree Box*. The few **FLOWERS** there are consist of *Erica hyemalis* and *gracilis*, *Trachelium cæruleum*, *Sedum Sieboldii*, *Primula sinensis*, fine, large, fringed varieties, both red and white; *Yellow Pomponé Chrysanthemums*, and *Ivy-leaved Geraniums*. **CUT FLOWERS** consist of *Camellias*, *Ceanothus azureus*, *Cinerarias*, *China Roses*, *Bignonia venusta*, *Verbenas*, *Clove Carnations*, *Snow-berries*, *Fuchsias*, *Heliotropes*, and *Scarlet Geraniums*.—
H.

The following is a list of the *Horticultural and Poultry Shows* of which we are at present aware. We shall be obliged by any of our readers sending us additions to the list, and giving the address of the Secretaries.

HORTICULTURAL SHOWS.

BURY ST. EDMUNDS, Nov. 26 (Chrysanthemums). (Sec. G. P. Clay, Esq.)

CALEDONIAN (Inverleith Row), Edinburgh, Dec. 2.

HAMPSHIRE, Nov. 18 (Winchester). (Sec. Rev. F. Wickham, Winchester.)

LONDON FLORICULTURAL (Exeter Hall, Strand), Nov. 9+, 23, Dec. 14+.

NORTH LONDON, Nov. 23, Chrysanthemum.

SOUTH LONDON (ROYAL), Nov. 11+, Dec. 9+, 16.

† For seedlings only.

POULTRY SHOWS.

BIRMINGHAM AND MIDLAND COUNTIES, 14th, 15th, 16th, and 17th December.

BRISTOL AGRICULTURAL, December 7th, 8th, and 9th. (Sec. James Marimont.)

CORNWALL (PENZANCE), January 10th, and 11th. (Secs. Rev. W. W. Wingfield, Gulval Vicarage, and E. H. Rodd, Esq.)

DORCHESTER, Nov. 18th. (Sec., G. J. Andrews, Esq., Dorchester.)

HONITON, January 12th. (Sec. H. K. Venn.)

WINCHESTER, December 1st. (Secs. G. W. Johnson and J. Colson.)

PINES: THEIR CULTURE.

(Continued from page 26.)

Our readers will remember that in the preceding papers on this subject the matter was brought up to the point of structures, interior fittings, heating, ventilation, atmospheric moisture, shading, &c. Cultural matters come next, and we must begin with *the sucker*, which is the favourite mode of propagation. Space will not permit us to indulge in verbose details, neither are they needed; we may merely observe, that the sucker makes a good plant more speedily than the crowns or gills, and that it takes less room. Those who have dined at public tables in a crowded condition, and have thereby been well elbowed, will readily understand the difference between them; the crown, in consequence of its highly recurved foliage, is much given to elbowing; and were our good friend Beaton's Yuccas to produce crowns as well as suckers, ten to one he would prefer the latter, for their habits bear a great resemblance. For the information of those who do not well understand the technology of horticulture, it may be observed, that the *sucker* is a reproduction from the root, or lower portion of the stem; *the crown*, of course, surmounts the fruit, and *the gills* are little excrescences, which nature, in her sportiveness, causes to assume the character, and, indeed, possess the functions of real plants.

Now, as not every one who reads these observations can build a house at once, and plant these suckers out in soil, we will show how these suckers are cultivated in ordinary practice. Of course, they come to hand at various periods under ordinary circumstances—the greatest bulk generally when the fruit is cut. If this happen any time between October and February, many cultivators leave them on the mother plants, termed "stools," in this condition, until February. Many come to hand, however, through other periods, for some plants produce more suckers than it is expedient to have, and as these come at different periods, it is the practice with some to dibble them in the tan at the front of the pit or frame, just like a cabbage plant. Here they will speedily root, and may remain until there are enough to fill a frame, a pit, or a portion of such, or until some re-arrangement of the stock takes place, when it becomes the cultivator to work them in with his system. On these occasions they are mostly potted, and if good plants, will require seven-inch pots, well drained. They are now, of course, plunged in a bottom warmth of from 80° to 85°, and henceforth the usual routine of culture is practised. They are repotted or shifted, when full of roots, into pots a couple of sizes larger, and thence into their fruiting-pots, when under pot culture; the period of the last shift being partly regulated by the time the fruit is required. The latter may generally be expected about nine or ten months from the final shift.

Now, if any one about to commence the Hamiltonian system could lay hands on a lot of strong-rooted suckers from these seven-inch pots, they would be just the thing; they would be purchased at a moderate

price, compared with fruiting-plants. Another excellent plan would be to purchase stools as soon after the fruit is cut as possible, and to plant these out at once.

And here it is necessary to interpose a few special remarks, for the guidance of those purchasers who are not experienced in Pine-culture. The first is, to beware of insects; not to receive plants at a gift, if at all infested. We are led to these remarks in a more pointed way from the tenor of an enquiry or two recently addressed to THE COTTAGE GARDENER; the querist asking if the crowns of imported fruit would not be a good beginning for one just embarking in Pine-culture?

Certainly, such must appear very feasible and economical in the eyes of the unknowing, but it is both a dangerous and uncalled-for procedure. These crowns are for the most part three-parts killed by the ordeal they have passed; but even this is not the worst; they may be infested with scale, bug, or other insects; at least, they are to be regarded with a suspicious eye; and, moreover, they may not be of the kinds best adapted for a British palate, a British sky, or a British market. Let anyone suggest to a good gardener the introducing a lot of these blistered-looking apologies for a plant amongst his healthy, glaucous-looking Queens or Jamaicas, which, like Cæsar's wife, are above suspicion, and they will speedily see his hairs stand-on-end "like quills," &c. No; if any one feels desirous of trying an experiment in this way, let him make the attempt in some pit or house which may never compromise the general system of Pine-culture. And not only may the crowns or suckers from importations prove foul, but those from home-grown fruit also, although the latter is of somewhat rare occurrence now-a-days. An exceedingly jealous eye, must, however, be kept on them, and the best way for those who do not understand Pine-culture, is to employ some experienced gardener to select them.

In looking over Mr. Hamilton's notes, in answer to certain enquiries, we find that he strongly recommends old stools wherewith to commence his system. He says:—"Let the beginner commence with old stools, with one or more suckers on, and plant them out at once. If old stools cannot be had, let the suckers be stuck in at one end of the pit, in a compost two-thirds leaf mould, and one-third soil. After they have made one foot of growth let them be planted in fresh turf. A fourth-part of the bed would hold the suckers; when well rooted, let them be taken up and laid aside, and their compost can be spread along the bottom of the bed, and the fresh turf can be laid on the top for permanent planting, and then there is no loss of time." It will be seen here what stress Mr. H. lays on old stools, which, however, are not always attainable. It so happens, that they are the very thing that most gardeners on the old or pot-system throw away; the only misfortune being, that they are apt to strip away every sucker of any size previously, and in this case, several months may be lost—a most important affair.

Those about to build should immediately commence a sharp look-out, and, perhaps, the best way would be to offer nurserymen, in Pine-growing districts, a certain value per head, specifying kind, and making *thorough cleanliness* a *sine qua non* condition. As to time of planting, that is almost a matter of indifference. To those determined to build, we say, do so directly, and get the stools all at once, or by instalments, as you can catch them, good and clean, and at as early a period as possible, only take care that everything is ready to receive them.

It will be well here, for the sake of the tyro, to explain a few technical terms pertaining to the Pine in its various stages. Gardeners, in general, use the following to express the character of their plants:—

Small suckers.

Strong suckers.

Successions.

Strong successions.

Fruiting plants.

Fruiters.

There may be some little modification of these terms, here and there, but such, in the main, express these gardening conventionalities. Their meaning is as follows:—*Small suckers* are inferior suckers, or suckers from inferior plants, and are generally under a foot in length (this, however, is dependent on kind); and in diameter, at base, a little over an inch. *Strong suckers* may be characterised as of at least double that strength; the former, by our potting-men, would be put in a five-inch pot, the latter in a seven-inch. When established in their pots, and full of roots, they become *successions*; those in the five-inch pots, the ordinary *successions*; and those in the seven-inch, *strong successions*; providing they have been flourishing. We come now to *fruiting plants*, and these, of course, mean plants prepared to show fruit, although such is not always the case immediately. There are certain marks whereby practical men can tell almost to a certainty whether the fruit has commenced rising, and when in sight it is called "a show." The general character of the plant, just previously, becomes considerably altered; it looks more compact, the outer leaves cease to elongate, or nearly so, whilst those of the interior advance, and also multiply as they advance. The whole plant, by this time, if robust, will, if pulled by the hand, appear firm in the soil as a stout shrub. *Fruiters* are those in which the show is complete, and this title continues up to the time when they begin to change colour, when they become *ripeners*—a term which needs no description.

Having now brought up the subject to what may be termed a fair beginning, as to cultural matters, we may just suppose a house of the kind built and ready for the soil; and here we may offer an extract from Mr. Hamilton's notes on the subject of soil, and what may be termed subsoil. It was before stated that, according to Mr. Hamilton, "there must be no chamber;" this, it will be seen, saves considerable expense. He uses, however, a good depth of rubble, and thus remarks—"Let the rubble cover the pipes three or four inches, and put three inches below, broken bricks, or boulder stones, &c." And here we may name a matter connected with the height of the building, although somewhat out of place. Mr. H. is for a very flat pitch in the roof, as most good Pine-growers are; the fact being, that in very steep roofs the sunlight is apt to be too intense in extremes of weather, and also that air moisture is much more speedily dissipated beneath such roofs—the steep roof being a more rapid transmitter of vapour in its ascent to the highest level than a flat roof; added to this, it is much more difficult to carry out the interior arrangements necessary for the Pines beneath a steep than a flat roof. Mr. H. wishes to have his Pines almost close to the roof—nearly in contact with it. He says, "The roof ought to be about three feet from the surface of the soil at front, and about four feet six inches at back." Now, any one about to plan, may just draw two perpendiculars at the desired distance, representing front and back walls, and, having adopted the proper slope for a roof, may just count his way downwards, allowing no more depth of walling than is absolutely necessary, and finally throw down a ground line at what height he pleases, which will amount to this, that he can, after planning the necessary depth of walling, build as much, or as little, above the ground level as he chooses. These things, however, are familiar to most persons; and in speaking of soil, Mr. H. says "twenty inches is deep enough." As to the character of the soil, Mr. H. prefers, where attainable, turf from an old pasture; and it will have been observed that he, in another place, speaks of

"fresh turf." If the loam, or turf, is heavy—that is to say, too adhesive, or containing too much of the clayey principle—he recommends using "a little decomposed manure, or leaf mould." In another portion of his notes he observes, "If the old pasture turf is not too retentive, I would use no manure."

Our readers must not imagine from this, that what is commonly termed a strong loam is to be held in abhorrence; but it is difficult to convey a just idea of what constitutes a loam to persons unpractised in gardening matters. THE COTTAGE GARDENER, although notorious for substituting plain English for an ambiguous style, has had, perhaps, more difficulty in rendering the matter of loam familiar to its inexperienced readers, than any other affair, in so small a compass. One thing, however, is evident, that Mr. H. is coveting the organic matter which is so abundant in old pasture soils, and which no compost prepared by hand can possibly imitate. It is not the mere quality alone, it is the mechanical texture that forms its chief feature; and whether it be a matter of capillary attraction, its conducting powers as to heat, or its long-continued permeability to atmospheric action, or whether all these are combined,—certain it is, that for many horticultural purposes we cannot find a substitute for this precious material.

For other remaining cultural matters we must refer the reader to subsequent papers, in the conclusion of which we shall doubtless have some discrepancies to reconcile, some errors to correct; and those interested in this rising taste, fancy, demand—call it what you like—will do well to watch the subject to its close.

R. ERRINGTON.

VISIT TO CLAREMONT.

I INTENDED to visit the great Rose nurseries this autumn, to see the perpetual Roses in bloom, and to hear the gossip of the day about Roses in general, but the weather turning out so wet in September must have spoiled the bloom; therefore I gave them up for the present, and went to see some good public and private gardens, and a few nurseries instead. I have often seen Claremont for the last twenty years, but not so late as this—the end of September—and I never yet left it without a string of fresh ideas. On this occasion, I found them in the midst of great improvements and alterations in the forcing ground, and busily finishing up the housing of half-hardy plants, which they grow to very large sizes, and in the summer they arrange them in pairs, singly, or in groups, in different parts of the flower-garden, and in the pleasure-ground, with the pots plunged quite out of sight in most cases; and this is a style of gardening which is carried out at Claremont better than at any other place that I am acquainted with. Indeed, all the house plants here may be said to be specimens, even to the plants from which they cut sweet-scented leaves and twigs for the nosegays, and the old and fancy Geraniums they force in the spring, for cut flowers, are all in great pots, and the plants look as if they were many years old, from their size, but in their aspect they appear as if their youth was renewed from year to year. By this system, the produce is often doubled from the same space of house or pit room, and with less risk to the plants, and less expense in looking after them.

Some of the specimens in the orchid-house are the largest in this country, and no part of Europe can boast of a pair of larger orchids than the two match plants, *Zygopetalum Mackayi*, here. I know of no place where the *Cactus*, or *Epiphyllum truncatus*, has attained such a size, as in one of the stoves or intermediate stove, grafted here on the, I believe, *Pereskia aculeata*. Here also the *Baumontia grandiflora* flowers as abundantly as at Shrubland Park, or with our correspondent

"Devoniensis." The *Euphorbia jacquiniiflora* is also very large, some of the young shoots being from three to five feet long, and when in full bloom, what a splendid wreath the tops of two of the shoots would make, placed in this fashion—one from behind each ear, with the points or tops meeting in the centre of the forehead, and then passing each other about two inches or rather more; to these add four more tops, same size as the first two, and form the six into a star, and my word for it, you would conquer the French President himself, in one night, as sure as ever his uncle was overcome at Waterloo.

But, instead of attending to ball-rooms, we are to see how they are going to provide more room for their greenhouse specimens at Claremont. The old, long house in the forcing ground, once called the "the succulent house," and afterwards the "greenhouse," is no more, and on its site is placed a specimen house, hard upon a hundred feet long, and fourteen feet wide; a broad walk down the middle, to enable them to pass up and down with huge bushes in pots, &c., and a stage on each side, much better than a slate stage, and quite as durable, and drained on the same principle as a garden-pot; thus, a succession of brick arches run along each side, with facings or kirbs next the walk, and a little higher than the crown of the arches. Now, the spaces between the arches are filled up, first with brickbats, then with rough cinders, and a finishing coat of finely-sifted coal-ashes, the whole on both sides being quite flat and level. Provision is made for letting off the drainage from between the arches into a drain. With this kind of stage the house can be kept very dry in winter, and as wet in summer as they choose to make it, without wetting the walk at all; and see what room there is for stowage under the arches. The house is to be heated with hot water, and the same boiler will heat it, and ranges of pine and other pits close by. When the whole is finished, and well proved, I shall ask for the drawings, and some of the specifications, for our pages. All the Pines are grown and fruited here in pits, and they fruit them very extensively every year; the plants look remarkably stout and healthy, with short, thick, and broad leaves—always a sure sign of well-to-do; yet Mr. Malleon says the French beat us out-and-out in the culture of the *Pine*, and that they get one-fourth more weight of fruit from a given space than we do. He was in France this summer, and saw fine Pines fruiting in No. 32 pots. He told me, also, that there is as great demand there for British gardeners now, as was in England once for Scotch gardeners, but for want of a knowledge of keeping accounts in the French way, and not knowing even the rudiments of the French tongue, our young men are not qualified for the Continent. The *Grapes* have also been equally fine this season, chiefly Black Hamburgs, and Canon Hall Muscats. Some of the bunches were a foot long, and the berries particularly large and well flavoured. The vines are pruned on the spur-system, and as soon as the leaves drop off in the autumn.

The Cornelian Cherry-tree (*Cornus mascula variegata*) was in ripe fruit, trained horizontally against a south wall. I never saw this plant so treated before, nor with ripe fruit on it; the fruit is very handsome, and good to eat; it is blunt at both ends, about the size of a small plum or sloe, and of a rich deep claret colour. This kind of Cornel is, therefore, a fit subject for a conservatory-wall, where no glass or artificial heat is used; and to get rid of the kitchen-garden idea, the plant should not be trained horizontally like a pear, but in the fan manner. The flowers of *Cornus mas*, as some people call it, are of no account—yellow little starry things in clusters, but they come very early in the spring before the leaf.

In another part of this garden there is an old plant

that is hardly known among gardeners, yet it is an excellent one for a small garden; it is ten feet high, and looks just as if it was a cross seedling between an ash and a walnut, and the fruit is like a walnut, but is winged. Where the *Ailanthus glandulosa* would be too large this would be a good substitute. The name is *Pterocarpa Caucasica*.

Most of the species and varieties of *Conifers* have been planted here, but the new ones are not yet of a size to attract much attention. *Deodars* twelve feet high; *Cryptomeria japonica* ten feet, and as much in diameter at the bottom; *Pinus insignis* about ten feet; fine plants of *Cunninghamia lanceolata* from twelve to fourteen feet; *Cupressus macrocarpa* eight to ten feet, and, being seedlings, grow up as straight as the Lombardy poplar; very fine examples of *Cupressus torulosa* from ten to fourteen feet.

A large plant of *Wistaria* covers 130 feet of a wall ten feet high, and one of *Chinanthus grandiflorus* eighteen feet of the same wall, and seeds freely every year; and as this is one of the most difficult of our hardy plants to increase by layers, this seed ought to be looked after wherever they ripen, as every garden, however small, ought to have one for supplying its deliciously scented flowers during the winter.

The moment I entered the garden I noticed a new flower-bed a good way off, but of what flowers it was made up, D. Beaton could not tell on the instant. It was a lucky hit by Mr. Malleon, and one that any planter can imitate, and much easier than the shot-silk bed, of which I have not seen a single instance this season that was not a complete failure. This new bed was made with the old rose-scented *Geranium* (*Pelargonium graveolens*), mixed with the *Verbena*, *Robinson's Defiance*. It was a large circle, and the *Geranium* was quite thick all over the space; and very likely few other *Verbenas* could stand so much smothering, for I could hardly see a leaf of the *Defiance*, but the bloom was as regular and thick as if there was no *Geranium* in the bed, and well up above the leaves, making the deception complete a short way off. Mr. Malleon told me that the *Beauty Supreme Verbena*—a pinkish variety, as strong as *Defiance*, or nearly so—planted in the same way with *Mangles' Variegated Geranium*, is equally effective; but these variegated *Geraniums*, and all the more delicate sorts, were potted and housed before I called. It happens very luckily, that every one who is fond of plants likes these two *Geraniums*—the one for the scented leaves, and the other as the best of all the old variegated *Geraniums*. Instead, therefore, of planting out the Rose-scented *Geraniums*, as at present, in all sorts of out-of-the-way places, merely to keep it going, or about the doors, to be rubbed and sniffed at on your going in or out; a bed may be made of it, or a large basket may be legally filled with it on the open lawn; and the scarlet *Verbena* will look more showy over the dark green and jagged leaves of the Rose-scented than in the more natural way, without the help of the *Geranium*. Now, I would advise, at once, a diligent search to be made for all the Rose-scented *Geraniums* that were planted out this season, so as to come in for a bed next year; we shall want plants, at any rate, for 20,000 or 25,000 of it next May, and therefore we cannot afford to lose the old plants; besides, it is ten to one if young plants struck next spring will answer so well as old ones, because the soil at Claremont is so favourable to the growth of this tribe, that they come to an enormous size by the autumn, and yet this last bed did not appear to be a leaf too strong at the very end of September. The plants, in another large bed, of *Diadematum rubescens*, a very moderate grower, were, on an average, two feet high, and some of them double that in diameter. I never saw such a sight before. I never could get it to grow above a foot at Shrubland; and at Kew, this

season, it did not even cover the ground at the beginning of October, although it was planted as thick as usual.

I saw another contrivance, a new move, which looked remarkably gay—a row of Black-eyed Susans, or *Thunbergia alata*, seventy-two feet long, from four to five feet high, and a yard through at the bottom, right out in the open air in front of some hothouses, but they were planted about four feet from the wall, and were staked just like so many Sweet Peas. They all looked as healthy and as full of flowers and seeds as ever any Sweet Peas did. There were three kinds of them mixed; but the white one—the real Black-eyed Susan of our impy days—looked the best. The wonder is that they escaped the red spider at the beginning of July, for naturally they grow much in the shade; and in-doors they do better trained up a dark, damp, back wall than full in the sun. To try this experiment, get a shilling's worth of mixed seeds; sow them in any light, rich soil, quite thick, about the middle of March, or, at least, before the month is out; place the pots in a brisk cucumber bed; and when the seedlings are two inches high, top them by nipping off the very points; and as soon as fresh shoots come out they are fit for potting, when they ought to have very rich, light soil, and to be put three in a pot of three inches over, unless the crop is scanty, when one plant will be enough for a pot. Never allow them to get above six inches high while they are in heat; that is the grand secret; as, when the pots are quite full of roots, and are put into cold frames by the end of April, they will make a strong push all from the bottom, and the foundation is then laid without forcing them. By the third week in May, they will stand the open air all day, and the light to be drawn over them in cold nights. As soon as the weather is mild and settled in June, plant them out in the very richest compost you can make with very rotten dung, leaf mould, fresh turfy loam, and a kindly aspect, and allow them abundance of water as soon as they take to the soil. Any one who can grow celery will find no difficulty with these, only they must not be planted in trenches; but if a space like a celery trench was prepared for them, then filled in with good stuff, and the balls planted entire on the top, you would have them as good as they were at Claremont with half that trouble.

In the centre of the garden were four beds of mixed *Portulaccas*, and each bed would need some hundreds of plants; they must have been most gorgeous earlier in the season, for even now, after a month's rain, they were not amiss, and there was not a blank in any of the beds. Mr. Malleon told me that in some parts of France they grow them by the thousand, and they do so well, that one can hardly look at them in the middle of the day; and, in the same gardens, the *Plumbago Larpente* is one mass of light blue all through the autumn, and the best mass plant they had from us for years.

A double crop of flowers is got here from that beautiful, dark, purplish-blue *Delphinium*, or Larkspur, called *Barlowii*, by cutting the whole plant down to the ground as soon as the flowers begin to fade in June, and, after awhile, giving some good soakings of water to the bed. The second bloom was in its prime when I called. A very large bed in one part of the garden is every year full of *Hydrangeas* in bloom, as regularly as a bed of tulips; the plants being treated as biennials struck from cuttings, and planted out to nurse the first year, and in this flower-bed the year following.

I knew, for many years, that the *Amaryllis belladonna* was better managed at Claremont than elsewhere, and I made a point of asking about it particularly on this occasion, and I found a whole row of it in front of a long row of hothouses in full bloom, and every root or

bulb in the row appeared to be exactly of the same strength, for, out of the whole, there was not a single stem an inch above or below the average height; they all stood as upright and regular as a regiment in single file, which I took to be a high compliment to the royal owner—His Majesty the King of the Belgians, to whom Dr. Herbert dedicated his large work on the Amaryllids. Mr. Malleson takes up all the roots every sixth year, in the month of June, divides them, and, after renewing the border with fresh earth, replants them in single line, placing the bulbs six inches below the surface, and nine inches apart, and about fourteen inches from the wall; behind them, and within three inches of the wall, he has a full row of mixed *Lias*s now in leaf, three inches high, and none of them receive any protection whatever, save what the leaves of the Belladonna afford. These *Lias*s are also allowed to increase and multiply for six years, then are taken up, divided, and the strongest roots put in again three inches deep, and they do as well as Crocuses. There was not a single gap or failure in either of the rows. Patches of both kinds are left in another border to take their chance, without being ever disturbed, as a lesson for the young gardeners to see the necessity of a regular course of culture for bulbs that would seem to most people to do well enough without any care whatever. There were other evidences in this garden of a desire to "teach the young ideas how to shoot," in cases where the requirements of the establishment did not seem to want such things.

I also saw a new plan for getting nice young flowering plants of the new *Jasminum multiflorum* for winter-flowering in small pots. This flowers in winter on the young wood made during the previous summer, and stools of it are planted out on a rich border, from which long shoots rise every year, and when the growth is nearly finished they are layered in small pots, where they soon root, and are then fit for the purpose required.

D. BEATON.

SHOWING OFF PLANTS IN ROOMS.

GROWING PLANTS IN ZINC VESSELS.

AFTER the article on floral boudoirs, to which myself and readers are indebted to the inquiries of a correspondent, some complaints have reached me, that I and others would throw cold water over the attempt to grow plants in windows and rooms, and thus deprive many of one of the sweetest pleasures that it is possible to realize. Sorry should I be that such an effect should be for a moment felt. The conservatory boudoir attached to the mansion would yield an amount of refined interest which plants in living rooms can but rarely evolve; still, the advantages of a floral boudoir may, in some measure, be realized, even in living rooms, by concentrating in one particular part all that is blooming and lovely—a measure which it is often needful and advisable to adopt, when, owing to peculiar circumstances, the proprietors will have their showy plants brought for short periods to the house to inspect them there, even though the idea should be felt, that the plants and their accompaniments are not quite in character with the elegant furniture surrounding them. To counteract this impression, I have recommended ornamental artistic pots for such situations, showing, from experience, with iron, porcelain, and china, as well as with common earthenware, burnt hard, or painted on the outside, that the popular trade error in favour of soft greasy pots was rather more than a delusion. In addition to this, it was recommended that, instead of having numbers of ornamental pots of a miniature character scattered about, it would be better to use common small pots for growing, and then to concentrate a number of these into orna-

mental vases or boxes, covered over the surface with green moss, and with a contrivance below to receive all the extra waterings, which otherwise might find its way into the room. In the case of an elegant box or basket, lined with zinc inside, this receptacle for water may be supplied in the shape of a drawer, waterproof, near the base line of the box. In vases, the lower pedestal should open for a similar purpose. It is an easy matter to make such a pedestal of wood, and with paint and sand it is as easy to make it resemble the vase, however ornamental.

Still, after all this was done, either in our own case, or that of our friends, there seemed to be something wanting to make up a sum total of agreeableness. If the flowers stood near the window, the want of a reflecting back-ground was at once felt. If they were placed farther in the room—at its centre, or near its side—not only was the want of a suitable natural back-ground felt, but the colour of the paint or papering of the room often made the plants look inferiorly different from what they did in their more appropriate homes. Now, the remedy for this would seem to be almost intuitive; very simple, indeed, when once named; and some of our clever contemporaries may have adopted various modes for counteracting the deficiency; but I confess I have seen or heard of no method so simple, and so likely to prove effective, as that practiced by Mr. Fleming, at Trentham—a place which every one fond of, or engaged in gardening, should, if possible, visit, whether his superintendance extends to a few yards or an expanse of acres; whether his views are mostly bounded by his window plants, or his mind rather delights to revel among the vexed questions of building, heating, glass-walling, &c., so characteristic of the day.

Well, in going round, close to the mansion we came on some elegant boxes, seemingly of mahogany or stained wood, with a trellis formed of rods of similar wood, fixed to one side, say the *back* of the box. The box itself was divided into three compartments—two small ones, one at each end, and a larger in the middle—each furnished with separate vessels, shaped like the box, and thus easily set in and removed at pleasure. In the two smaller compartments, at the ends, *Ivy* was planted, and trained over the trellis, thus furnishing a beautiful back-ground. The largest centre division was reserved for flowering-plants, turned out of pots, or grown as hereafter to be mentioned. I forget the *size* of the boxes, say somewhere from three to four feet long, from one to one-and-a-quarter wide, and from nine to twelve inches deep, and the trellis from three to four feet in height, to be tall enough just to reflect the beauty in rooms of such gorgeous plants in winter as *Poinsettia pulcherrima*, *Euphorbia Jacquiniflora*, &c., of which there seemed to be great abundance of fine, young, healthy plants. The size of the boxes is of less importance, as our amateur friends, when once they take the matter up, will vary the size of the boxes, and the height of the trellis, according to the plants they wish to show off. One box might thus have several trellises ready to put off and on at pleasure; and even the vegetation on the trellis might be changed, to suit the size and colour of the flowers, by keeping plants growing and trained in pots, or, better still, in vessels suited to the destined compartment. If well managed and trained previously, there would be little difficulty in fixing them to the ornamental trellis. My mind instantly reverted to many plants as suitable for this purpose, such as the *Vinca major* (the Periwinkle) for large plants, and the *Vinca minor*, in its various forms of green, white-variegated, and silver-variegated, for low-flowering plants. So far as I recollect, Mr. Fleming seemed to have used the *Ivy* exclusively, and that he had found it to stand room-treatment well, with the advantage he gave it of not exposing it too much when first bringing the boxes

out, and then giving them a good breathing-time out-of-doors.

But, as bearing not merely on this subject, but on ornamental pot-gardening, however used, Mr. Fleming mentioned a fact which is well worthy of being more generally tested—namely, that he found plants to flourish better in *zinc vessels* than in any other he had tried. He considered that, from the conjunction of the earth, water, and air, with the zinc, a galvanic action was promoted, in which the plants delighted. Now, I had frequently sown all manner of seeds, and inserted nearly all kinds of half-hardy cuttings into worn-out zinc evaporating pans, flat, and also with round bottoms, and though the things did well enough, I never noticed anything particular about them—in fact, I never made any note on the subject at all. As “seeing is believing,” Mr. Fleming took us to see plants so growing; among others, he pointed out oblong boxes, with two or three Poinsettias growing in them, just of the size to fit into the ornamental boxes, with attached trellis above referred to; and certainly, in contrasting them with their neighbours in pots—and those in pots enjoying individually rather more room and soil, and every other circumstance in common—if there was a shade of difference where all were healthy, the zinc-potted plants had a deeper, blacker green in the foliage. Now, the above fact is one that many a man might have got gold by in the ancient days of exclusiveness. Whatever may be made of it by the trade, and we sober-sided, stand-still practicals, as our more theoretical-progression friends at times call us, it opens up a fine idea for the amateur of refined and artistic tastes. I cannot say how long zinc will last when used for such purposes, as certain waters are apt to corrode it; but, at any rate, it is not so liable to injury as either pots or china vases; it is light, thin, easily moved therefore, and easily inserted inside of other vessels, and requires but little ingenuity in the workman to bend and twist it into all manner of classic and artistic shapes; and as it is cheap, and may be coloured at will, it may thus be instrumental, either as smaller or larger-sized vessels, for banishing the red earth pots from the windows of our cottage *orneés*. In opposition to the maxim, that “prices rise with the demand,” I believe, in this and many other instances, that prices would be moderate in proportion to the numbers of the article wanted. A beginning here may soon lead to greater improvements in our utensils for plant culture.

R. FISH.

TALL LOBELIAS.

(Concluded from page 45.)

In my last paper on these plants I described the mode of raising them by seed. The next head is raising them *by slips or cuttings*, and it is a fortunate circumstance that they are easy to propagate that way, so that any one possessing two or three plants may soon have quite a stock.

The time for this operation is in autumn, just before the plants go out of flower. Frequently they will produce on the flower-stems short leafy shoots—these make the very best cuttings. Also the flower-stem itself may be cut into short lengths, that is, with two buds or joints. The lower joint should have the leaf cut off, and the upper one should have the leaf belonging to it preserved. The pots for these cuttings should be well drained, and filled with rich light soil, well pressed down, with a thin covering of fine silver-sand on the surface. Whilst the cuttings are being gathered and made, give the pots so filled a gentle watering, which will settle the sand, and make it firm by the time the cuttings are ready. With a smooth stick, about as thick as a good quill, plant the cuttings round the pots close to

the edge, turning the leaves so that they may point inwards; they may then be set closer together without interfering with each other. Press the cuttings firmly to the pot side, and fill up the holes with a little more sand, then give a gentle watering, and place them in a gentle heat, or, where there is such a convenience, in a regular propagating house. They will root in a shady part of a greenhouse, but not so certainly or quickly. As soon as they form roots they should be potted off into three-inch pots, and be allowed to remain in heat for a fortnight or three weeks; then place them near the glass in the greenhouse, till they have filled the pots with roots, when they may be allowed to go to rest, but should be kept just moist enough to prevent them losing their roots through the winter. If well managed, about the month of March they will begin to grow again, and will form fine plants for flowering that year.

By Division.—Where room is scarce, and the kinds plentiful, this mode of increase is the least trouble. As soon as they have done flowering, cut down the flower-stems and take up out of the bed or border a number of plants; reduce the ball of earth, and pot them into as small pots as the plants can be got into without crushing. Place them either in a greenhouse or a cold frame, well protected from frost; give water about once a month in case they should be very dry, or if they have been grown in pots, as soon as the bloom is over, cut down the flower-stems, and place them in the same situation through winter. When the warm days of spring arrive; several shoots will be seen springing round the centre of the plants. As soon as that is perceived they may be divided at once. Take a pot in that condition, turn the plants out of it, and shake a large portion of the soil away; then with a sharp knife divide the shoots from each other, preserving some roots to each division, and one or two young shoots; pot them into as small pots as they can be got into without crowding the roots. Place them near the front glass of a good greenhouse, or in a frame kept close and warm till the plants begin to grow, then give plenty of air, and a fresh potting as soon as they have filled the pots with roots.

This is the conclusion of my remarks on propagating these fine flowers. I find I have incidentally included under this head that of *wintering the plants*, and in consequence need not repeat it, but commence now with

The Soil.—To grow these plants well in pot is an important point in culture. When *Lobelia fulgens* was first introduced, a very clever gardener, now no more, a Mr. Hedges, gardener to the Earl of Mansfield, at Caen Wood, was very successful in growing and blooming them. The soil in which he cultivated them was a very rich one, consisting of loam, peat, and well-rotted cow dung. This grew the plants very strong with plenty of foliage, but not so much bloom as we require now-a-days. The soil that I have found to answer best is turfy-loam, peat, and leaf mould, in equal parts. This gives a sufficiently strong growth, and the plants flower more abundantly. To sustain and bring out the bloom, I give, as soon as the flower-stems have decidedly appeared, a weak solution of manure-water every third time they require moisture.

General management and preparing for Exhibition.—The general management consists in re-potting several times during the earlier months of the year. This causes the plants to continue growing strong for the time, and enables them to throw up several strong flowering-stems to each.

Watering.—The Lobelia is a water-loving plant, and therefore, to grow it well water should be given liberally. When the plants have received their last shift into the blooming-pots, nine inches in diameter, and these pots are filled with roots, it will be found advisable to place pans under each pot, to catch the water that passes through the pots, but it must be allowed to dry up sometimes.

The place to grow them should either be a deep pit or on the stage of a greenhouse. To prevent accidents, it is desirable to place a small stick, painted green, to each flower-stem, tying them rather slackly with soft matting. These sticks may remain till the plants arrive at the place of exhibition, when they should all be removed, excepting the centre one. The stems should be strong enough to keep their position. Each stem should bear a long spike of flowers, seven or eight of which should be in bloom at the time; each bloom should consist of petals that are broad and highly-coloured, whether the colour is scarlet, purple, or blue. The best number, or at least a sufficient number for a stand, will be six. That number will include all the best varieties at present known, but if a greater variety is raised, the number may be raised.

Lastly, *Hybridizing*, in order to improve the varieties. This is done in the usual way, that is, by cutting away all the anthers from one flower before the pollen cases burst, and applying the pollen from some other variety, possessing qualities desirable to add to those possessed by the one to bear seed. The flowers thus hybridized should be protected from bees and other insects by a covering of fine net muslin. T. APPELEY.

JOTTINGS BY THE WAY.

(Continued from page 44.)

In the course of my journey I visited the ancient town of *Coventry*, famous for the somewhat apocryphal history of the Lady Godiva and Peeping Tom. There happened to be an *Exhibition of Plants, Fruits, and Vegetables* that day, and I was much gratified to see so many good things on the tables. The gardener at Lord Leigh's, of Stoneleigh Abbey, had good well-bloomed plants of *Allamanda cathartica*, *Stephanotis florabunda*, *Pleroma elegans*, and others. The fruit was also respectable, and the vegetables excellent. It is delightful to observe, at country exhibitions, the very excellent vegetables produced by cottagers: it was especially so to myself, having been so long connected with a work partly devoted to their instruction; and I do not know a more acceptable and useful present to an industrious, hard-working cottager than the first two volumes of THE COTTAGE GARDENER.

On the same day, I had a great treat in visiting the gardens at *Keursley House*, three miles from Coventry, belonging to the Rev. Mr. Thickers. Mr. Craddock is the gardener. There I saw a noble specimen of that beautiful fir the *Picea Welbiana*, a handsome tree with all the branches symmetrically arranged, and not one in the least injured by frost. I may venture to say this is the finest specimen in England. It was full sixteen feet high, and ten feet through. It is planted on the lawn in front of the house, which stands on a considerable elevation. The garden is sheltered on the north and west sides. The subsoil is a kind of shaly rock, with a thick coating of good loam upon it. These circumstances, no doubt, were favourable to the growth of such Coniferæ as are rather tender, like the one I am describing. There was also a thriving specimen of that fine tree the *Abies Douglassii*, twenty feet high and twelve feet through. This specimen was also perfect;—not a branch was wanting to destroy its symmetry. *Abies Menziesii* had reached twenty feet high and ten feet through. The lowest tier of branches reached to the ground, and were regularly disposed up to the last produced tier, forming a truly unique, handsome specimen. *Cupressus macrocarpa*, or *Lambertiana*, was twelve feet high, and a fine, well-clothed-with-branches specimen. There were also thriving trees of *Cryptomeria japonica*, *Cedrus Deodara*, eighteen feet high; *Araucaria imbricata*, and a very green tree of *Araucaria Cunninghamii*, perfectly healthy;

besides many others, more common and of less note, belonging to this tribe. In another part of the grounds I observed a good healthy tree of *Benthamia fragifera*. I was informed that this tree had not as yet fruited. On the rock-work, which is rather extensive, there was a good collection of British Ferns; and in the garden where the glass-houses are, I observed good plants of Heaths and New Holland plants. The place altogether is not very extensive, but is kept in excellent order throughout. I am sure any lover of rare and beautiful, healthy, Coniferæ, as well as other plants, would be as much pleased as I was to view so many unique specimens in so small a place. It is a beautiful drive from Coventry, which is the nearest point by railway to it.

The neighbourhood of Coventry abounds with gentlemen's seats, which are well worthy of spending two or three days in seeing them, especially *Stoneleigh Abbey*, about four miles from Coventry. This place, with respect to gardening, is undergoing considerable alteration. Mr. Nesfield has laid out, in his peculiar style, a new terrace garden, and a large new conservatory is just finished, but not filled with plants, at least it was not when I was there. The present owner seems to be a very kindly-hearted man. The day I visited the place he had a large number of poor children at the hall, and was giving them a feast. Never did I see a happier or merrier group of children; the lord and lady were quite as happy, and as harmlessly merry as the young urchins they were entertaining. It was, we understood, the second birth-day of the young heir that occasioned the holiday. It is such kindness that endears our aristocracy to their dependants. May such kind-hearted nobles increase to render the poor happy and contented.

The kitchen gardens are extensive, and also improving. In one new house I noted a large number of vines in pots to be fruited therein; they were almost as strong as those on the rafters; the wood was ripening beautifully, and they will, no doubt, bear a plentiful crop next year. A span-roofed lofty vinery had been at one end replanted, and the vines were growing strongly. This kind of vinery is rather common, but I know none that shows off the vine so beautifully.

On the road to Stoneleigh Abbey is *Styvechale Hall*, the seat of G. Gregory, Esq. The gardens here are improving much under the fostering care of Mr. John Ashton; and a little distance off is *Whitley Abbey*, belonging to the Hon. Mrs. Hood. This is a very ancient place. I was much pleased with the rock-work here, which is not artificial; the natural rock has been bared to a great extent, and planted with deep rock shrubs and herbaceous plants, and is the most unique thing of the kind I have seen. T. APPELEY

(To be continued.)

WINTERING CAULIFLOWER PLANTS.

It is generally admitted that the production of early Cauliflowers, in conjunction with that of Peas, forms the line of demarcation between the winter and the summer products, which in each the garden may be expected to furnish; and it seldom happens that the Cauliflower, under ordinary circumstances, can be brought into bearing immediately the last Brocoli of the season goes out, an interval of a few days (certainly not more than a week) occurs before this important vegetable takes its place. Now, though it is well known that Brocoli (or Cauliflower either) will keep a few days hung up in a cool place, if not too much stripped of leaves, yet it is always advisable to arrange the planting and other conditions, so that the succession may be such as to dispense with the "preservation system" as much as possible, more especially so at a period when vegetation is so much on the alert as to act in an inverse ratio with

the keeping qualities of the article in question; now, in order to have Cauliflowers as early in the summer as possible, means must be taken to forward their growth in such a manner as to ensure their arriving at maturity in the shortest possible time, as in the case of many other things, the attempt to accomplish this sometimes leads to an opposite extreme. The rearing of plants too early in autumn causes them to attain a sort of matured growth sooner than they ought to do, and the consequence is, they present us with their premature heads long before they have attained that size which is requisite for their usefulness. This is what is called "buttoning," and is just exactly what the skilful cultivator tries to avoid. Now, though we have occasionally had such mishaps, and every one who tries to have his produce early must expect some of the plants to run thus prematurely to head, yet the fewer of such useless productions the better, and the only way to prevent its happening, is not to sow too soon, while to delay that duty too long is attended with risks from another quarter;—the young plants, unable to stand the rigour of winter, either perish, or if they live, cannot possibly come in early; but as all this has been explained, I will suppose that a seed-bed, well furnished with robust plants, is just waiting to be planted out.

A well sheltered border facing the full south, but defended on all other sides, should be dug and manured, adding as much mortar-rubbish as can be had, to expel the slugs and other enemies that may be lurking there. This ground must then be measured off in such a way as to give space for the tops of the hand-lights being taken off, and still afford room to walk through and examine them as required. The common sized square hand-light will hold nine plants, which, after planting, may be covered up a few days to assist them in forming roots, and otherwise establishing themselves; after which they may be gradually uncovered, so as finally to inure them to the cold air, when the thermometer is not too much below the freezing point. A mild, dull season, encouraging an unhealthy growth, is at variance with the plant's preservation when severe weather does set in: fortunately it often happens that very sharp frosts are preceded by more or less of cold chilly weather, which hardens the plant so that it endures the frost with less injury than if a severe frost suddenly followed an open mild season.

Though there are various modes of obtaining early Cauliflowers, this old-fashioned one may still be regarded as the best; but another way is to have a quantity of plants potted, which being partly protected and partly forced, are planted out in March, on some well-prepared situation, as under a south wall; yet it does not always happen that such are the earliest after all, and when the extra trouble is taken into account, the odds lie certainly on the side of planting under hand-lights; or, if they be wanting, a common frame may be placed in such a situation, and filled with plants, which, being treated exactly the same as the above, may be thinned in spring, and the residue left to grow where standing.

It very often happens that both frames and hand-lights are required to protect the necessary number of plants that are wanted in spring; and, in fact, if frames be not wanted for anything else, it is better to appropriate them to this purpose than allow them to remain idle. Now, in addition to the above modes, many temporary ones are made use of with equal success. A bed is made and surrounded with rough slabs, sticks are hooped over it, and a few longitudinal ones being added, mats or other covering are thrown on in hard weather: and with this purpose in view the size and shape of the bed is made in accordance with its covering. In a mild winter, and in the south of England, they will but seldom want covering up; but, in more bleak districts, this will be more wanted: in the latter case, a greater

breadth ought to be planted under glass, if possible; and, in very severe weather, that will be the better for a little covering up, if snow does not affect that purpose.

In the general management of plants in positions as above, it is to be understood that a robust growth is to be encouraged, rather than a delicate, tender one. A little frost ought never to hurt them, which it assuredly would, were they nursed in a temperature more suited for geraniums; in the latter case, the elongated leaves, and the general development of the plant at a period at variance with the state of things out-of-doors, renders it very unfit to withstand any amount of hardship. Nothing is better to harden this, or any other description of half-hardy plant, than the cold drying winds we sometimes have in autumn and winter; the chilling effects of this suspends all growth that may be active, and by contracting or sealing-up those pores, which, in a more excited state, rendered the plant liable "to catch cold," by every cold draught, inures it to that condition in which its constitutional hardihood is put to a fair, yet not severe, test. When hard weather really does set in, it is better to open the frames or hand-lights a little, to allow the damp atmosphere to evaporate. Let us suppose a clear sunny afternoon in December, or January, which we know often betokens a sharp frost; on such an occasion, let the plants be very much exposed, and when shut in, both they and the ground they occupy will be less charged with moisture than previously; and if even a little crispy stiffness from frost has caught hold of them, they are no worse, providing they have been properly inured to cold previously; with this care they may be covered up for several days, if a succession of severe weather forbids their being opened; as by being partly chilled, or shall we say "benumbed"? the active powers of vegetation, as well as of decay, are very much checked: the latter being hardly less important than the former. Care, of course, must be taken in re-opening them to the currents of cold air, but the dull weather that usually follows the "breaking up of a storm" facilitates that; everything being done in the mean time to gradually accustom them again to full exposure. By attending to these simple rules, the amateur will be able to carry his plants through the winter with that degree of robust health which is the only safeguard to a successful issue.

J ROBSON.

ALLOTMENT FARMING.—NOVEMBER.

At last we are arrived at that part of the year when the vegetable kingdom, for the most part, sinks into a state of repose—a not less wondrous provision of Almighty God than that cheering activity and exuberance exhibited in the garden and the field during the spring and summer. By this annual repose, the exhausted soil is enabled to lay in a store of the necessary gases, or qualities derived from the atmosphere; a great proportion of the insect tribes, which otherwise would accumulate in a most destructive degree, are destroyed; and, in addition, the earnest cultivator is enabled to carry out improvements connected with the staple of the soil without loss of time in regard of cropping. To the latter point we would direct especial attention. We never saw a plot of ground yet but that something might be done for it still in the dormant season—something to increase its value and efficiency; and as long as we have the pleasure of conducting out-door operations of this kind, we shall aim at no lower a standard than annually making the land worth more than it was in the preceding year. This may seem a bold standard to assume, but we are persuaded that in the majority of cases it is attainable.

Amongst the most solid and lasting improvements, draining may be pointed to; without this, all other appliances are but a waste of property. By it, where soils are sour, both organic and inorganic matters are brought into play that would otherwise remain inactive; the cultivator is

enabled to deepen his soil—a most important matter at all times, as affording continuous nourishment to the roots of crops during protracted droughts; and, in addition, the labourer is enabled to work his soil with half the trouble.

But one of the most important features connected with draining remains to be pointed to—we mean the increase of ground warmth. Our labouring friends, who are more familiar with the spade than the pen, may think this a trifle, and may stare when we tell them, that not only the gardeners' pine-apples and cucumbers require a bottom-heat, but that it is beneficial in a high degree to most of our ordinary crops. To say that a given plot of ground, five degrees of warmth in advance of an adjoining plot of equal extent and quality, will produce earlier vegetables, is to affirm what needs little consideration; but we go a step farther, and affirm that it will produce more abundantly. Providence has so ordained it, that the ground heat over most of the habitable parts of the globe is some two or three degrees higher than the air heat, taking the averages; so that means taken to increase the ground warmth are not so artificial a proceeding as would at first sight appear.

Next to draining, we regard the improvement of the staple the most important matter, and one, of necessity, facilitated by the former. However, we would not rest content with that amelioration which proceeds as a mere consequence, but carry matters farther. It only requires to appropriate a little of the beer-shop money and time to such matters; not that we suppose, by any means, that many of our readers in humble life are in the habit of thus squandering their time, although we do know that such characters are to be found in all countries; long may they form the exception.

We have not space here to go into details of advice concerning "staple improvements," but may merely point to the fact, that lime-rubbish, and cinder-ashes, burnt moor soil, and such like, are well-known improvers of the staple of clays; and that marls, burnt clay, ditch or pond scourings, peaty soils, &c., are of much benefit to burning sands; and lime, strange to say, has been found to benefit both.

We must now proceed to examine the position of the allotment or cottage garden, and its crops, stores, &c. And first,

POTATOES.—This has been a grievous year as to this invaluable root; great have been the complaints, and, we are sorry to say, great the losses. Nevertheless, so great is the breadth planted, that we are assured the country will be pretty well supplied after all. It appears that the potato has, in these days, a double ordeal to undergo; the first, when the "plague spot" first overruns the whole system of the plant, quite perverting its juices; the other, when the tubers are removed, and, as is too much the case, permitted to ferment, by being placed in a considerable body. These are crises in the character of the potato of latter days which deserve a little study. As to the former, all seem alike at fault; a cure is out of the question; preventives are the chief consideration. No man in his senses can doubt—however much or little it can be made to bear on the disease question—that well-preserved seed must lead to better results, in some form, than neglected or abused seed. We will at once take this for granted, and then the question is: how to preserve seed well? Common sense teaches the veriest clown, that when a potato has sprouted, part of the virtue or energy is exhausted; and that in a state of nature this process takes place in the soil; the conditions almost diametrically opposite. The former, or artificial, condition of the tuber being one exposed, perhaps, to a high amount of perspiration or fermentation, and to a capricious medium; the latter to darkness, and a sort of quiescent state. We merely throw out these observations to set our allotment-men thinking during the long winter evenings; and we advise them to persevere, and not doubt but that the potato will one day be restored to them in its original purity, however long the ordeal may be through which it has to pass.

STORE-ROOTS.—We come here to the general principles of store-root preservation, which are few indeed, and exceedingly simple. These are the points—

- Dryness.
- Exclusion of air.
- Absence of fermentation.
- A low temperature.

As to the first, they can hardly be too dry, if the dryness is accompanied by a very low temperature; if we could select or lay down a pitch, we should say 35° to 40°. Exclusion of air is but another term for darkness, which is, indeed, an essential; and, in general, what promotes the one accomplishes the other. Exclusion from the air prevents loss by perspiration; and darkness prevents a tax on the growing tendencies of the crowns of such roots as Mangold, the Swede, Potatoes, Carrots, Parsnips, &c. Fermentation, caused by placing roots in too great heaps, robs them of a considerable amount of both their nutritious and keeping properties: this is the very bane of many proceedings. A low temperature is another important affair. *Rest is the maxim* with all these things; to this end northern aspects must be sought, and other local advantages, taking care that a high and dry situation be selected. No lodgment of waters must ever be thought of where roots are stored. Thus much about roots in the lump; we have not space for detail. We may, however, observe, that it is well with all store-roots to cut the crown somewhat "into the quick;" the growing principle is thereby crippled for a longer period, and, indeed, weakened. Mangold should be immediately got in, the roots scraped with a piece of stick cut to an edge, and housed dry, if possible; if there is no room in any outhouse, they may be piled, in a dry state, on a piece of high and dry ground, and simply covered nine inches with soil, taking care to sharpen the exterior to a ridge, to throw off rains. Swedes may remain on the ground for another month, for they are very hardy; and, as the Mangold tops are now in use for the pig, &c., the Swede tops may thus be made to succeed them. Parsnips may remain where grown all the winter, unless needed off-hand. Our practice for many years has been to trim off the leaves in the early part of November, and immediately to manure the ground for the succeeding crop; then to open a trench a good depth at one end of the row, and thus provide for trenching them out as wanted, at the same time ridging the soil ready for the succeeding crop. Land, thus treated, is in fine order the following March for any crop of importance. Carrots will, of course, be stored, as they are tender; we cut their tops completely to the quick—a plan named twenty years since in Loudon's Magazine, and which we have practised ever since; it assuredly keeps the roots fresh much longer, and no injury has ever arisen from the practice.

CABBAGE-WORTS.—We long since explained that this broad term was intended to express all those greens, whether Cabbage or not, which are in these days worked into the general cropping economy—some preferring one kind, some another. If we were in a position to grant allotment land to the industrious, we should assuredly take all the lawful means in our power to persuade or to coax our tenantry to secure a sprinkling of these over all portions of the land occupied by summer crops. We are led to these remarks by observing, in a late northern trip, some of the finest soil "that ever a crow flew over," as our Cheshire peasants have it, lying totally idle for the winter, after a crop of rotten potatoes, and this, too, land bringing some three to five pounds per acre. This is really a pity; the time is not far distant when every pole of English land will require to be kept in high cultivation most of the year, in order to keep pace with a stretching population, hungry as the famous Egyptian locusts. Well, all Cabbage-worts will bring to hand half-decayed leaves, which are useful to the swine, at least; and, as these are removed, advantage may be taken to cultivate between them, both for the sake of the existing crop and its successor. What is termed "soiling-up," although condemned by some, is, according to our experience, quite the thing; it prevents the plants wind-waving; it destroys a crop of weeds; it admits air to the soil; and it does more, it causes the plants to root up the stem, thereby rendering them more profitable.

RIDGING.—This was pointed to before; but as a good tale is none the worse for being twice told, we beg again to refer to it. Our advice, then, is, let every yard of land, on which no crop is standing in the end of November, be deep dug, and thrown into sharp ridges.

ONIONS.—Keep your Onions dry; yea, warm if you will, sooner than permit any damp to lodge about them. *Leeks*, if growing, as they should be in drills, should be soiled up like celery some dry day.

RHUBARB.—Those who want this early, with small expense, should cover the crowns with any dry litter as soon as the leaves can be stripped away, which will generally be in the first week of November. "An empty house is better than a bad tenant." And so with such things. Jack Frost had better be kept at a respectful distance.

CABBAGE PLANTS.—Let all those in seed-beds, not required this autumn, be immediately "pricked out" in store-beds, three inches apart. Ours are already done, the soil dressed well with the covering from charred heaps, in order to ensure a clean and healthy plant, which it assuredly will.

ORDER.—This is a strange title to finish with; but let everything be in its place, and walks and ditches cleared by the middle of the month. As far as our experience goes, order is closely related to thrift. R. ERRINGTON.

THE APIARIAN'S CALENDAR.—NOVEMBER.

By J. H. Payne, Esq., Author of "The Bee-Keeper's Guide."

THE requirements of the apiary are but few during the present month, provided that *feeding* has been well attended to in the last; should it, however, have been neglected, no time must be lost in setting about it before cold weather sets in, which may now reasonably be expected.

FLOOR-BOARDS.—It will be well to clean the floor-boards, and (the season for robbing being pretty well over, and the wasps having now finished their maraudings), to have a final examination of all the stocks, securing them well against wet, and making them up, by feeding, to eighteen or twenty pounds each.

REMOVING SUPERS.—All super as well as nadir hives should now be removed, reducing the room occupied by each stock as much as possible.

VENTILATION.—In hives of wood I have always found it necessary, during the winter months, to withdraw one of the slides at the top of the hive, and place over the opening a feeder, or small glass, for the purpose of carrying off the condensed vapour, which would otherwise run down the sides of the hive, and cause dampness and mouldiness to the combs, and sometimes the entire destruction of the stock. Mr. Taylor gives a drawing of a condenser for this purpose in his *Bee-Keeper's Manual*, page 142, fourth edition, which I have found to be very useful, where a feeding-pan could not well be placed.

NORTH ASPECT.—The accounts that I continue to receive from persons, who, at my suggestion, have thus placed their bees, are, hitherto, *all* in favour of it. The advantages arising from it during the late hot weather have certainly been very great, but we must watch it through another spring before it can be generally recommended.

DIVIDING HIVE FOR OBTAINING ARTIFICIAL SWARMS.—I have just received the following letter from my friend, Mr. Taylor, author of *The Bee-Keeper's Manual*, and as it contains much interesting matter on this and other subjects, I will give it at length, for I feel assured the writer will excuse my making use of it.

"I hope you will be able to preserve the dividing hive* through the winter, that we may see what becomes of it next season; so far as we have gone, we know the *principle* is right, and that the thing will *work*; though I am somewhat in the same sceptical position as to artificial swarms as are Dr. Bevan and Mr. Golding; of course, I mean as a general rule, for they are sometimes, doubtless, desirable, and it is well to have the means of accomplishing the business, which I think my hive does, without much risk, trouble, or disturbance. There are, however, other uses I have in store for it, as I mentioned to you, of equal, and, perhaps, greater importance than swarm making. Both Dr. Dunbar and Miner, speak of dividing hives, but I followed my own devices in making the one you have. The one alluded to by Dunbar, is, doubtless, that of Feburier, whose work he translated, though it was not published. Dr. Bevan told me a Welchman once brought him one of these

* I have had one of these hives, which was kindly sent me by Mr. Taylor, at work since June, and find that it acts perfectly, so far as taking to pieces goes, which may be done at any time, with very little trouble, and still less annoyance to the bees. This hive is so constructed, that I have no hesitation in saying that an artificial swarm may be obtained from it at pleasure during the months of May and June.

dividing hives to inspect, as an original invention, and, perhaps, it was even so, although it appeared an exact copy from Feburier's drawings. These I never saw, and am rather curious to know how far we agree. I should always be inclined to caution in accusing any one of plagiarism as to invention, or as to an original idea, particularly where bees are concerned, for hundreds and thousands of heads and hands have been at work on their behalf for centuries. I could name some instances in my own case. You will recollect when I told you, some years ago, I had been scheming to find out a mode and utensil suitable for feeding at the top instead of the bottom of a hive; I had never heard of such a procedure previously; but you had been in possession of a top-feeder for forty years; and, moreover, when Dr. Bevan's second edition came out, there was the very same thing, or nearly so. And so it was as regards feeding with barley-sugar, which the good Doctor recollected to have seen used by a friend many years ago, without farther thinking of it. By-the-by, if you want to defend the passage into a hive against an invasion by wasps, you have but to put a bit of barley-sugar across the mouth, and out will come such a body of bees that no enemy will face them. Repeat the dose as fast as they eat up their fortification, and the wasps will sheer off in despair. The idea came to me from Dr. Bevan. I once read an account of a new invention, by some one, for obviating the evil of damp in hives, in winter, by condensation, precisely the same as had been published by me for years. And yet, afterwards, I discovered that a friend had used the similar means two years before *me*, with success. So you see how often people hit upon the same ideas. I could mention other things; such, for instance, as a method communicated to me lately (as a secret), for washing a hive with salt and water previously to hiving a swarm into it—a practice I recollect in a district in Norfolk half-a-century ago. I saw it tried in two cases forty years since; in one instance with success, and failure in the other. Can it be right to insure a damp hive always in wet weather? Even *THE COTTAGE GARDENER* of the 16th of September furnishes something like an example of a similar nature, where fumigating a hive from the top is alluded to, as if it were something new. All my editions, I think, mention it; but at pages 104 and 124, *third edition*, and page 138, *fourth edition*, it is described. Whether I was the first to think of it, I do not know; but I have often practised the thing (particularly down the ventilators in Nutt's hives), though, in general, common hives do not offer the necessary facilities. The requisite tube is a bent one, which, if you were a *smoker* instead of a *driver*, I would send you. I am inclined to agree rather with Dr. Dunbar, who is a mighty champion for smoke, in many operations on bees. However, we all have our own fancies in such matters, and, perhaps, it is as well each to practice what he best understands and succeeds in. I ought to have said, that the instrument I always have used is what is called the Oxford tube, a moveable one, as opposed to the lamp form, which seems only adapted, as I conceive, to *bottom-fuming*. Even for that I like the other best, as more easily regulated.

"And now you will like to hear how the Observatory hive goes on, in which, as I told you, the bees had from the first been working, exposed to the full glare of day-light. Of course, work is pretty well over; but there is a fair store of honey. I never lost sight of the queen during an inspection of half-an-hour yesterday; she is become sluggish and inactive, and not an egg proceeded from her, though a while back she laid them incessantly, to mere waste. I think I told you she was a *young* lady; but I have since found that the swarm was a prime one, and her appearance confirms it. Her extreme fertility had almost made me a convert to the doctrine of young queens as the best breeders, which, you know, I had many doubts about. My own observations would seem to lead me to the belief that a queen bee does not arrive at her full powers at first. Dr. Bevan spoke decidedly on this point in a letter, which I think you saw. For myself, I have observed that an early second swarm, and a late first one, coming at about the same time, and not much differing as to size, did not prosper as well relatively as might be expected, one queen being young and the other old; the latter, in short, increasing the population the soonest and the most. It might not be so always,

perhaps, though a second swarm rarely becomes very populous. At all events, the question of advantage rests in so much equilibrium, that I had rather, in most cases, let nature alone, unless in some obviously extreme emergency. The *oldest queen* on record was one of Mr. Goldings, which, at four years of age, or nearly so, filled the hive so full of brood of all kinds before she died, that a large swarm issued soon after (in May), and four more subsequently. As regards the question of bees working in the light, I can only say, that so far as I have seen, they appear to care nothing about it, *if used to it from the first*. Alternations between light and darkness does not do; and they are alarmed where one or the other is not continuous. I saw a hive thus working, exposed to the light, many years ago, I think at Oxford; but the experiment, I believe, is hardly likely to lead to any very useful practical result beyond ascertaining a fact. I mentioned the hive I am now working (altogether of glass at the sides) to a friend, who told me he once saw a number of wooden hives at work, and all without shutters to the windows, of which most of the hives had two. The owner, in answer to a question, replied, that he found the bees did not care about the light, and he left

off making shutters to save trouble. In winter, I should say they would be needed; and, on the whole, I should prefer them. However, you shall judge for yourself next year, when I hope to send you a *light hive*. The good old Doctor is to have one; and he tells me he has already in his mind decided as to where it is to stand. We have just emerged from an argument as to the nature of a *drone egg*, leaving off where we began. You will be grieved to hear that his eyes have failed him of late; his own admirable hand-writing being of late exchanged for that of a secretary.

"I mentioned to Dr. Bevan that the Entomological Society had offered a prize for the best essay on the duration of life in bees, of which I thought he knew more than any one. He says he could do no more than repeat what he has already written. The question, indeed, appears to me to have been settled fifteen years ago by him, Dr. Dunbar, Mr. Golding, and, I think, Sir William Jardine, beyond farther dispute (see the "Honey Bee"). But, judging from what has recently appeared as to bees in the name of one of the magnates of the said Society, they do not seem aware that the world has kept moving of late years."

FLOWER-GARDEN PLANS.—No. 1.

THIS, the first of our series of flower-garden plans, was sent to me before the subject was announced for publication. The author is a friend, and a clever gardener, and he had no idea at the time he sent it, that either his "tracings," or anything about them would ever be made public. Having fixed on this plan for our first number, some delay was necessary, to obtain his consent to publish it. He made no observations on the plan the second time, and all that he said in the first letter, was this—"I send you tracings of a flower-garden, which I have some thoughts of laying down here. What do think of it? The colours I merely put down for your good-natured criticism. But I always think a *few well-defined and distinct colours* better than a larger number. Don't you?" I do think so, for that is the grand secret, after all, of planting a flower-garden for effect. Some plant more, to show the extent of their bedding-plants, their scarcity, and so forth, and pride themselves on the greater number of species or varieties they can thus introduce, and when the space is large enough, and the sizes and position of the beds are such as to allow of all that being effected in "a well-defined, and distinct manner," that kind of pride is very excusable. Some day or other, I shall give the best instance I know of that way of planting a large flower-garden. Meantime, I shall give two reasons for fixing on this for the first plan; first, because the colours are given without mentioning the plants for producing them; thus leaving the field open for young planters of both sexes to exercise their taste a little, and send us the names of such plants as *they* would plant in this garden, and this I earnestly invite young artists, as we may call them, to do. Then, after a few months, I shall criticise all that are sent to me, and give the way I would plant myself. As the plans will be numbered, there will be no difficulty in referring to any of them at any future time, and there is a long time before us, between this and next May, without any occasion for pressing on our different styles of planting. All the time that I served at Shrubland Park, the final arrangement of the flower-gardens there was not settled before the middle of April, and those fine gardens have been allowed to be among the very best in the country; and in another year or two, when the whole of the great improvements now going on there shall have been completed, I should not be far

- | | | |
|-----------------------|------------|----------------------|
| 1 Blue. | 5 Blue. | 9 Bright pink. |
| 2 Dark purple. | 6 Yellow. | 10 Brilliant orange. |
| 3 Dwarf box, clipped. | 7 Scarlet. | 11 White. |
| 4 Bright pink. | 8 Blue. | |

from the mark, if I were to say that would be the finest place in England for flower-gardens; and then I venture to say that it will be late every spring before they will settle how the whole is to be planted.

My second reason for this plan is because my friend has introduced a new feature in it, for the first time since I began to plant flower-gardens. I mean his introducing Box as a *relief*, or green colour in beds No. 3, between the dark purple in beds No. 2, and the blue in beds No. 1. This style is all but quite new in this country. I only know of a few places where box-beds, or beds of some flowerless plants are used; but on the Continent, I hear the plan is common, and I know that some old foreign authors treat of this style as quite familiar. The different coloured gravels, pebbles, and sand they use in Italy, in their Italian gardens, is part and

parcel of the same; but here, with our moist climate, and our superabundance of half-hardy and fine-leaved plants, we need not resort to such extremes. Yet, white sand and yellow gravel formed good auxiliaries to many of Lady Middleton's compositions, which we had to fill up; and I know of several places in which some of the old Cape Geraniums, with inconspicuous flowers, are used this way, with very good effect as *reliefs*, as we call them; a new name that I shall have to use often in this series. Then we shall have *neutral* beds, *relief* beds, *mixed* beds, or subdued colours, as well as the more common terms of *harmonious* beds, and beds *contrasted*. I am anxious to have box beds, and box scrolls introduced into geometric gardens, as well as Yuccas, Irish Yews, and a little dwarf Spruce called *Abies Clanbrasilensis*. These last two for strong contrast; the Irish Yew as a slow-growing and fastigate, or quite upright growth; and the *Abies* of much slower growth, and quite flat on the top, with a round head. Also the Irish Furze (*Ulex stricta*), and *Juniperus prostrata* and *squamata*, for the same purpose—strong contrast.

The Irish Furze, or Gorse, is a highly architectural plant; quite as much so as the Irish Yew and Yucca. It was first discovered in the Marquis of Londonderry's Park, in the county of Down. It is soft and silky in the leaves and branches, and bears the knife so well, that it may be formed into almost any shape; square on the sides, round, and sharp-pointed, or flat on the top. The prostrate Juniper makes a beautiful bluish-grey carpet to fill a round bed with, and it can be cut to any shape, and is also a fast grower in good soil. The same are the characteristics of the Juniper called *squamata*, only that it is a stronger growing plant. It could be made into little weeping standards a yard high in the stem, and then be allowed to weep down gracefully on all sides. The culture and propagation of them, as novelties, for the geometric garden, I shall explain shortly; mean time, I have one or two observations to make on the plan before us.

I object to the four entrances at the two ends and two sides, in a garden of moderate extent, unless you have a walk all round it, or a terrace on one or two of the sides; it lessens the effect of the picture, if you allow your visitors, or "company," to walk on straight to the middle of the scene at once, as they will be sure to do, seeing a straight leading walk before them, and as sure as they do, one-half of your garden is, in a manner, lost to them. This is a prevailing fault all over the kingdom, and in compositions, otherwise most beautifully arranged, I would prefer each pair of beds, No. 6, to be united as they now stand, or to be circles or ovals, at the expense of having more gravel at each end. Then your visitors are put off the "follow-the-rest-like-the-sheep" way of looking over the garden, and still they have a choice of right and left, and then the chances are, that some of them will go this way, and some the contrary way; always a lucky hit for the gardener, who prizes himself on his pet points. There may a trick in this, but depend upon it, the thing is as I say, for few gardeners have had more experience in leading companies through such scenes than your humble servant, to whom all this is as familiar as A. B. C.

I highly approve of beds, No. 3, being planted with dwarf box, and that as thick as possible, to be clipped on the outsides like an edging of box, and either as flat on the top as a dining-table, for the sake of uniformity, or as round as a globe; and if rounded on the top, the height to be in proportion to the diameter of the bed. In this instance 18 or 20 inches would be about the proper height.

I would prefer the circular beds, No. 9, to be green also, but not with box; then all the circles would be green—that is, uniform; a capital and practical explanation of the word, as we gardeners apply it; but how can we make a *variety* in a thing we call *uniform*? Nothing in this world so easy; plant No. 9 all round with the Rose-scented Geranium, and keep the growth regular with the knife all the season, and the thing is done to a T; and how lucky that 9 is so far from the centre, and from the middle walks, and, therefore, requiring a higher plant than No. 3, which is under the eye. Still my alteration for No. 9 is not a principle, and I have no right to insist on it, being only a matter of taste or opinion. The disposition of the colours by the author of the plan has my unqualified approbation.—D. BEATON.

EXPERIMENTS ON FEEDING COCHIN-CHINA AND SPANISH FOWLS.

I HASTEN to redeem the promise I made, of stating the results of my trials as to what was the cost of the food of Cochin-China fowls, as compared with that of others.

In the course of a few days, I hope to be able to say what has been the consumption of food (under exactly similar circumstances) by Dorkings, Bolton Grays, and some more Cochin-Chinas. In the mean time, it will be seen that these experiments very nearly verify what Anster Bonn, some time ago, in THE COTTAGE GARDENER, assured us was the case (though her opinion since then seems entirely to have changed), viz.:—"That when common poultry are fed twice a-day, it is necessary to feed Cochin-Chinas three or four times, and to give the food so abundantly that some may be left after the fowls have satisfied themselves." For while Spanish fowls have eaten at the rate of 2d. a-week, the Cochins have cost 3½d., 3¼d., and 4d. This has been, of course, where there is no farm-yard, which is, I think, Anster Bonn's case.

Before detailing how these trials have been carried on, I may add, that I give you my word that they have been tried in the fairest possible manner. Nos. 1, 2, and 4, have been carried on under my own eye. The food weighed out, and the birds almost entirely fed by myself.

In 1 and 2, the birds had the range of a wire cage, about 16 feet by 9 feet, with a small house attached to each cage. I believe the children were in the habit of feeding them with bread, &c., but the poultry never left the inclosure during the week. They were also supplied with green food.

No. 3, besides being fed as by the list, had the run of a large plantation and a stubble field. I have published the weights, which (varying as they do, some having increased, some diminished) may interest your readers. This lot was not under my own eye, but I have great faith in the accuracy of the person who carried on the trial.

No. 4 had the run of a large grass field and plantation. I am quite sure of the accuracy of the quantity of food consumed, and you will see, that under similar circumstances, a lot of thirteen Spanish poultry, of various ages, ate very little more than five Cochin-China cockerels.

The Spanish hens in lot 4 were deep in the moult, and laid no eggs; but, pray observe, that the Cochin-China eggs (few in number as they were) did not average *two ounces* each. I may add, that I have a Spanish pullet who now lays eggs weighing *three-ounces-and-a-quarter*. These are facts, which I leave to the consideration of the readers of THE COTTAGE GARDENER; but I ought to say, that I thought the fairest thing would be to buy my corn in small quantities (by the bushel), as a cottager would be forced to do. The prices I actually paid, were for

Barley, bushel of 60 lbs.,	4s. 6d.,	1d. per lb.
Wheat, "	70 "	6s. 3d., 1d. "
Indian corn, "	60 "	4s. 0d., ¾d. "
Meal, "	60 "	6s. 3d., 1¼d. "
Bran		¾d. "

These are the weights and prices of this county for good food, and I believe it will not answer to a gentleman or a cottager to feed poultry on bad food.

I leave my cause to plead for itself, believing that *truth will out*. I fancy it is even now prevailing, as I have letters before me from three poultry fanciers, who do not know me as "Gallus," but who write—"I am relinquishing a capital breed of Cochins. I wish to revert to the Spanish, which I once kept. The former are certainly good layers, and very hardy, but their eggs are very small, especially when compared with the Spanish, and they are *enormous eaters*."

"I am giving up Cochins. They are good layers, hardy, and good flavoured, but they are *enormous eaters*, their eggs very small, and they are very awkward-looking birds when cooked, their thighs being so large, and their breasts being *anything but plump*."

"I have been in the habit of keeping poultry for several years, and have calculated their cost per head, in the summer months (say from May to August) at *about 1d.* for hens, and 2d. for cocks. From August to May, when they require better food, they cost me 2d. per head, besides which they had scraps from the house. The breeds I keep are Spanish, Gold and Silver Pheasant, and Game. I tried

the sort now so much in fashion (the Cochin-Chinas), and I considered they ate about double what the others did."

So much for the opinion of three unprejudiced people! I have only further to say, that if any of your readers still think that 1d. a-week will keep a Cochin-China fowl, let them (as I did) weigh out 1 lb. of barley (which is about that value), and see how soon a Cochin-China will eat it.

I believe we deceive ourselves in saying "our poultry only eat so much," for we forget the bread, the potatoes, and other scraps, which would, if the cottager kept a pig (as I advise every one to do), go towards its food, instead of to the poultry, so that if the fowls cost less, the pig costs more.

I am very glad, for my own sake, that I made the experiment, and I am firmly convinced that the time is not far distant, when many now opposed to me will be ready to own I am not very far wrong.

GALLUS.

Time of Experiment—Oct. 4 to Oct. 11.

[NOTE BY THE EDITOR.—We readily declare our belief in the accuracy of the above report, because we know the writer to be an honourable man; and we have but two objections to make to his experiments, and they are these: First, that he did not have his Spanish fowls separated into threes and five, the same as the Cochin-Chinas. This is not an objection for objection sake, but founded upon our own experience, and the experience of others, that two or three fowls by themselves will consume proportionately more food in a day than when a great number are fed together. Whether this is the result of the few being less interrupted, and having less to divert their attention from the food trough, we shall not attempt to explain; but this we know—fifteen fowls fed together eat less in twenty-four hours than the same birds divided into threes, and fed each three in separate places, eat in the same space of time.

Our second objection is, that we have not the weights of the full-grown Spanish fowls, as well as the weights of the full-grown Cochin-Chinas. We suspect that the weight of the latter must be nearly double the weight of the former, and, if so, it is not so great a marvel that they eat nearly twice as much.

We have tried one experiment ourselves upon this subject very recently, and it yields a very different result, explicable upon no other grounds, as far as we can see, than that the birds were all fed together, and that ours in the south have not the keen appetites bestowed upon their brethren in the north, by its colder breezes.

Our experiment extended from Oct. 13th to Oct. 19th, both inclusive. In one yard were fifteen cockerels, and in

the other twenty-seven hens and pullets, all pure-breds, from the stocks of Mr. Punchard, Mr. Moody, and Captain Hornby, with the exception of three hens imported from Shanghai, and two hens, crosses between Cochins and Dorkings. Their respective ages and average weights (in the morning, before being fed) were as follows:—

	lbs.
9 cockerels, aged three months, average weight	- 2
4 cockerels, aged four months, average weight	- 4
2 cockerels, aged six months, average weight	- 6½
8 pullets, aged three months, average weight	- 1½
6 pullets, aged four months, average weight	- 3¼
9 pullets, aged six months, average weight	- 4½
6 hens, average weight	- 6

They were fed upon the following articles, to which we append the weight and price:—

Barley-meal, 46 lbs. per bushel, 3s. 9d.

Barley, 42 lbs. per bushel, 3s. 9d.

Oats, 35 lbs. per bushel, 2s. 9d.

Rice and greaves, averaging 1½d. per lb.

They were fed in troughs, barred across the top, so that they could not trample in the food, nor waste it in any other way; the troughs were never allowed to be empty, and they had a roomy yard, with access to grass for an hour or so daily. The supply of water unlimited. They consumed during the time—

25½ lbs. barley-meal	- - -	25½
4 " bran	- - -	2
14 " oats	- - -	14
14 " barley	- - -	14
4 " rice	- - -	9
2 " greaves	- - -	9

63½ lbs.

64½ pence.

So that the 42 fowls consumed food which cost 64½d. in seven days, being scarcely more than three-halfpence per week each. If this had been a cheap potato year, so that boiled potatoes could have been partly substituted for barley-meal, we are certain that the expense would have been nearer five farthings a week. As in the experiments by "Gallus," the corn was bought of a retailer; if bought by the quarter it would have been somewhat cheaper. During the week the six hens laid seventeen eggs, weighing from 2¼ to 2½ ozs. each, and two double-yolked eggs, weighing 3 ozs. each.]

Anster Bonn in a letter, from which the following is an extract, says—"I enter on the subject now, for this last time, from a desire to reply, with all willingness, to "Gallus's" question. At the dinner to which he refers, the opinion of the fowls in the dining-room was not pronounced so decidedly as out of the dining-room, because it was, on both sides, somewhat repressed by politeness. Although, from keeping but one kind of fowl, I lack the opportunity to join in "Gallus's" experiments, I shall feel great interest in their result; in aid of them, I can only offer the knowledge which I possess. The cost of corn and meal of various sorts to me, during the whole month of September, was £3. 4s. 6d, and the number of fowls being 140. This (about five farthings a-week each) gives rather a greater increase on the preceding months than I expected; but among these fowls are included fifty cocks near maturity: an extravagant disproportion, which would scarcely be tolerated by persons desirous of feeding with economy."

VISITS TO SOME OF THE CHIEF POULTRY-YARDS OF ENGLAND.

[MR. STURGEON'S.]

TIME was, and that within the memory of those who do not wish to think themselves old men, that a trip down Father Thames to Gravesend was an uncertain, and therefore somewhat serious undertaking. If the wind was favourable, and the tide suited, the light little river craft, then called "packets," ran you down merrily enough; but if the breeze failed, and the tide was against you, great was the consumption of patience—and tobacco. Independent of the wind, and comparatively but little affected by the tides,

the introduction of steam-boats put a new face upon the matter, and ultimately the formation of the Blackwall Railway, and an arrangement between the Directors of it and the Steam Packet Companies, to run in connection with each other, have reduced it almost to a certainty. By these means the inhabitants of "Cockneyshire" exchange the smoke of the city for that of the steamers upon the Thames; enjoy a stroll over the new town of Gravesend, and drink their own porter in the gardens upon the hill, where, at the time we have first referred to, we used to shoot rabbits. Of these gardens we may again speak upon a future occasion, but it is of a spot at an intermediate stage of the journey that we propose to-day to discourse.

We will suppose, then, that the reader has taken his ticket at the Blackwall Station. For 1s. 2d. by the first, or 10d. by the second class, he may travel by rail to Blackwall, and thence by the steam packet to the village, once, we are told, the market town of Grays, which is situate on the Essex side of the River, three or four miles before you reach Gravesend. One of those useful wooden piers, so common upon the Thames, runs far enough into the river to enable the steamers to land their passengers in any state of the tide, and for this accommodation sixpence additional is charged.

Leaving the toll-house behind you, you will observe, at a distance of a hundred yards or so, an old square manor-house. This is the dwelling of Mr. Sturgeon and his family; and let us whisper to you, kind reader, that if you are often in the habit of visiting a more hospitable mansion, you are, in our opinion, an exceedingly lucky fellow. We assume that such of our readers as are poultry-fanciers will have heard and read, more or less, of Mr. Sturgeon's Cochinchina fowls; and having told those who were not before aware of it how to reach their abode, we are now about to communicate to such as are unable to avail themselves of that information and to see for themselves, the result of a recent visit to Grays. Let us say, first of all, that here is no pretension to a handsome or costly poultry-house. The Messrs. Sturgeon farm a large tract of land; their poultry, consisting of Cochins exclusively, are kept as part of the stock of their farms; and all that is aimed at in the buildings and places in which they are located, is just sufficient to insure their health, their comfort, and their safety. There is, moreover, none of the nonsensical mystery of concealment—learned, we suppose, from the tricks of the dealers—which are seen in the yards of some of our fanciers; at Grays all is freely shown, and all as frankly told. The history of Mr. Sturgeon's flock is a brief one. His first birds were a present from the captain of a vessel, who brought them direct from Shanghai. The cock was killed by a fox, and the stock was reduced to the hen, which was sitting, and her embryo brood. From these, with the addition of such new blood as he has been enabled more recently to procure, the judgment and attention of Mr. Sturgeon have produced his present magnificent stock. Let our young fanciers derive hope and encouragement from these facts, for each of them has now better opportunities than, five years ago, Mr. Sturgeon possessed.

We have stated that there is no display at Grays. At the back of the house, at a corner of the kitchen-garden, is a plain shed, much such an one as we shall presently have occasion to describe; in this Mr. Sturgeon's breeding birds, or the best of them, abide during the spring months, and their "walk" is a part of the kitchen-garden. It is fenced off from the rest by a length of wire, over which you can step, but which the birds never attempt to pass, so easily are they confined. They run about under some raspberry bushes, and among the cabbages; and we were surprised to see how little mischief they appeared to do. The floor of a small grapery, at the opposite corner of the garden, is given up in early spring to the young broods, who have here light, air, and warmth, and are allowed to run out a little in the middle of the day.

At a distance of a few hundred yards from the house, and near to a little wood, sloping to the south, is the cottage of the intelligent man under whose care the birds are principally placed. Adjoining this cottage, and at a little distance from each other, are two sheds, measuring perhaps (we speak from memory) fifteen feet by ten feet, built of wood, and thatched with reeds from the marshes. There are no

perches, the floor being of open rails (perhaps three inches wide), and the rests are composed of wooden partitions at the end. Excepting those located, as we have said, in the garden adjoining the house, these are the dwelling-places of the best of Mr. Sturgeon's stock, their run out being into the wood and field adjoining. At Ockenden, about five miles from Grays, is another farm occupied by Messrs. Sturgeon. Here are a mill and a lodge-gate, at each of which places a similar plain shed is erected; and in these, and one or two more such at convenient points on the farm, the rest of the birds are parcelled out in lots. Our readers will see, from this simple description, that, although they may, perhaps, not need so many, it is not difficult for them to provide for their feathered favourites places of abode to the full as good as those which Mr. Sturgeon finds sufficient for his. We should ourselves suggest the addition of a perch about eighteen inches high, for which we have found nothing so good as a fir pole split down the centre, the round side being upwards, and the bark left on.

It remains to say a few words of the birds themselves, for it is to them, in truth, and not to see the places in which they are kept, that a visit to any poultry-yard should principally be paid. The prevailing colour of Mr. Sturgeon's birds are the different shades of buff and yellow, with such an admixture of other varieties as the most judicious crossing cannot prevent. The system of dividing them into lots, suitable to the amount of accommodation afforded by each "walk," and of separating the sexes as soon as they are fit to leave the mother, which the number of Mr. Sturgeon's separate "walks" enables him to carry out, promotes the growth, and improves the plumage of the young birds. Having bred, during the two last seasons, extensively, he has had abundant opportunity to select the most perfect in form and colour, and his judgment has made the most of his opportunities. Hence it is that Mr. Sturgeon's birds have carried off the prizes at all the shows (save, we believe, one) at which they have been exhibited, and although others may, and probably have, bred some birds as good as his, we doubt if at this moment any poultry-yard in England can show so many good, with proportionately so few indifferent, Cochins. A reference to our advertising columns shows that our readers may have an early opportunity of testing for themselves the correctness of the opinion we have expressed by looking in at the sale of Mr. Sturgeon's surplus stock at the Baker Street Bazaar, on the 2d November, and perchance some of them may even become the purchasers of some of the fowls of which they are now reading an imperfect account.

We should, perhaps, add, that there is nothing particular in Mr. Sturgeon's mode of feeding his poultry; the different species of our own grain, some whole and some ground, and mixed with water (a little sweet milk, where it can be spared, is an improvement) with occasionally a few tallow-chandler's greaves, being the staple of their food.

We take leave of Mr. Sturgeon and his flock, sincerely wishing him a good sale, and thanking him and his family most sincerely for their courtesy and hospitality to those whose good fortune it has been, like our own, to visit them at Grays. B.

THE SHELDRAKE AND ITS HAUNTS.

(Concluded from page 51).

The stile at the foot of the wharf (nobody can call it a *quay*) is mounted, and here at once is a charming and novel promenade. On the left, just across the channel of Blake-ney harbour, are the salt-marshes, in the state they remain from natural causes. We will have a stroll over them another time. On the right are the valuable marshes of Cley, reclaimed by the simple but costly erection on which we are treading. Several hundred acres have been inclosed by a mound of clayey soil. The ditch formed by its excavation acts as the main drain; a sluice-gate lets off the superabundant water at lowest ebb,—and that is all. *Here* are fat sheep and oxen grazing; *there* are gulls and all sorts of odd things. *I like* the odd things, and hope they will not be exterminated; but they will have a hard battle soon. From this to Weybourn all is to be brought into trim order; and then the rest of this line, as well as the marshes round

the other corner of the coast, will follow. Were I only born to a thousand acres of salt-marsh, half of it should be devoted to the preservation of unpreserved game. But the local papers already display a long advertisement headed, RECLAMATION OF LAND, and concluding with a signature, "Solicitor to the Bill." Farewell to the salt-marsh of olden time. Farewell to wild swans, ruffs, and reeves, and sheldrakes.

The circumvallating ridge makes a bend, and we now have a fine view of what, were we out at sea, would be called the line of coast, for the sandy flats and marshes are thence invisible. The parish church, standing on elevated ground, is the central object, with its curious supplemental beacon-tower, and the low sunlight gleaming through its windows. On the left are the pudding-shaped hills of Sheringham and Weybourn; behind that broad and lofty knoll on the right, dwell the cockle-gatherers of Stiffkey. Yes; take care of your hat: till to-day you hardly knew what "an airy situation" meant. Other breezes may waft the luxurious odours of the spices of Arabia; this bears something better on its wings,—a healthy, hungry appetite. *This* chestful of air, at least, has not passed through a thousand pair of lungs before entering mine. If one had but in one's frame-work a reservoir for fresh air, as the camel has for holding a store of fresh water, it would be worth coming here to breathe once or twice a week. Talk about plants and shrubs purifying the atmosphere, and throwing off oxygen! give me this, fresh from the north sea, for the gale to blow in *my* winter-garden. How delighted the little wavelets are, jumping in the harbour, running races to the shore, and friskily displaying their white shirt-frills! Give them a little more room, and they would soon grow into sturdy full-sized breakers. 'Tis a comfort to know that we could not lose our way wandering along this bank, even if we were caught in a fog, or had lingered after dark.

The tide is ebbing, and the boat awaits us. To get to it, we must pass—what were under water when we mounted the bank—the small pits, or dépôts, where shell fish are kept for daily use,—shallow hollows, dug out on the shore, ten or twelve feet, more or less, square; for the squareness is as uncertain as the size. *Parcs aux huitres*, or oyster-parks, the French would call them. Each pit seems to contain a small collection of mussels at one end, and of oysters at the other. See that rough-looking fellow with his mussel-rake, of eight or nine flat iron teeth, through holes in which a coarse net is laced. In fact, the implement is at once a rake and a landing-net; with it, he first collects his treasures in a heap, and then lades them out to the dry land, to be picked and cleansed, and packed in hampers. Mark the oysters, too, mostly lying with the *hollow* shell upwards, their natural position in the sea, instead of, as we have seen them packed in barrels, with the *flat* side uppermost. Oysters in the sea, laid wrong, will contrive to move till they get themselves right. People who doubt the vivacity of the oyster should visit these pits on a hot summer's day; the spitting, and spurting, and rattling of the assembly, will astonish them. The whole bed of the channel, or "cut" whereon we are about to embark, is covered with oysters and mussels, belonging to different proprietors. These chain cables, reaching across the bottom from shore to shore, mark the limits of each. Great part of our way down to the cockle-grounds will be over oyster and mussel pits or "lays," as they are called, stored with growing or fattening fish: oyster-parks, also, on a larger scale; for the oysters are dredged along the coast, and brought hither; and the mussels, too, are fetched principally from Lynn Deep and the Wash. Those *musselmen* who are not pressed for ready money, find that it pays to let these mussels remain *two years* in Blakeney "lays;" they grow and improve so much by the change of water. A mussel, when it comes to table, can hardly be less than four years old; a periwinkle, five or six. Cockles attain an indefinite age; in proof whereof the best and finest samples are only to be had from newly-discovered beds. You will note in returning, when many of these pits will be left by the tide, that the mussels are laid in deeper water, and much less exposed to be deserted by the tide than oysters. The smaller mussels, that have not thus been put up to fatten, are, in England, used rather for bait than for human food. The fisherman scoops out the

mollusc with his knife, and attaches it to the hook, raw. Whelks, which are also used as bait for cod-fish, are cracked with a hammer on a stone, and hooked *alive*. They are the best of bait; so tough that they never drop off, even if they are not taken by a fish for a week. Whelks are collected on several points of our coast, and are eaten largely by the children of the natives, although not by townspeople hereabouts. For the youngsters they are simply boiled; when adults partake of the mess, they are usually finished off in the frying-pan. Neither these, cockles, nor periwinkles, are kept alive in *vivaria*, or pits, or *parcs*, but are gathered, for the occasion, from their native.

The boat is manned by our polite host, who takes the helm, and by a second hand—in appearance a round bale of blue flannel, standing on two posts, that are encased in blue worsted stockings, and terminated by a short leather casing, to represent shoes. The entire package shall be veiled under the assumed name of Mr. Blackfaced Broadback, if it is possible to conceal anything so bulky. The sail is available for this reach. Down we glide. Overhead flits a pair of curlews, whistling their measured cry. The gun is on board: it would be pleasant to take home a few fat specimens of those. The culinary world is scarcely aware of their roasting merits. We turn to the left, and enter "the Pit:" the sail must come down. A pair of oars with the tide will carry us fast enough. A little flock of Stints wheel round us, and alight on the muddy shore that has arisen from the waves not ten minutes ago. Paddle gently up to them; there they run. Make ready! Present! Bang! There lie some of them; but how to get them? We've no dog. The boat is run aground. In jumps Broadback, up to the thickest part of his blue posts. *He* care for wet feet! Well, the game is not much, though some. Off quickly, or the tide will leave us stuck fast here. The *cockle-iferous* sands are yet too *quick* to venture on; what shall we do? Here's the pilots' house, standing on that wonderful tongue of sand and shingle, called "The Meals," before alluded to. Let us get out and walk, for we have at last arrived at the land of the Sheldrake. This is the *tide-pole* belonging to the pilots, reminding me of what I knew of Robinson Crusoe's almanac in younger days—a northern nilometer, measuring (upwards) the depth of the German Ocean. "What water was it at the pole?" is the twice-a-day question at Blakeney. They are not Trinity-men, but privileged denizens. Eight is their number,—four at a watch. None are here at this state of the tide, so we must be content to peep in at the window. The glass is dull; but the little round hole, through which their telescope is thrust, has not that defect. See, they have bed and board; that is to say, hammock and bench. In the middle is their stove, to heat the kettle and fire the frying-pan. It is placed *there* to economise warmth by its flue. Those square boxes contain each its owner's signal lantern and apparatus. One specimen lantern hangs on the hook there. The hut is but a dingy hole; still we should think it a paradise, if we were dragged into it after having been shipwrecked on the *sea-side* of the Meals. Yesterday I saw a woman (the wife of a master of a collier) who last week passed two days and a night lashed to the mast of a wreck. She was just beginning to recover the shock to body and mind.

Walking around the hut, one says that the pilots might improve their fashions; they are too Scotch in some matters. Proceeding, we find ourselves in a new world. How absurd to run over to the continent for *novelty* alone, till a man has ascertained what there is to see in his own country. Sand, shingle, and mud, are our three elements, or rather materials here. Wind and water are the two rival autocratic powers. The wind has a powerful ally in the Marram grass. *Wind* steals sand from the beach; *Marram* appropriates it, and keeps it. Mount this hillock, and the dodge is detected. You will also learn why sheldrakes are styled burrow ducks. Sand-wreaths are formed on the same principle as snow-wreaths, and do not melt. In these the rabbits burrow, and prepare nesting-places for the sheldrakes. Our dry sandy shores produce another grass, the *Poa bulbosa*, peculiarly fitted to inhabit such ground. Its bulbs grow in clusters, resembling little shallots, and during most part of summer remain inactive, blown about at random. With the autumnal rains they vegetate, fix themselves

by long downy radicles, then produce thick tufts of leaves (a grateful spring food for cattle), and in April or May they flower, having in the meantime formed young bulbs, which, as soon as the herbage withers, are dispersed like their predecessors. This summer dispersion is the cause why the plant remained so long unknown to botanists. Has any one been here with a vast bread-grater, and grated brown-bread crumbs over that muddy hollow of four or five acres? They are the casts of the marine worm, which here socially enjoys itself. The bottom of the next pool is dotted with an infinity of black spots, not the size of a peppercorn. Look at them: they are baby periwinkles, to make feasts for human babies that are as yet only "on their way." These are the food of the tender sheldrakes; with a daily supply of these, I could have reared my pretty pair.

Correspondents pester editorial gardeners to know what ornamental shrubs will grow within the influence of sea-breezes. We are in the midst of patches of one that would ornament any lawn. The *Salicornia fruticosa* has the unusual appendage of evergreen, succulent, hardy leaves. Are you gardeners enough to make it grow with you? I have managed to keep it alive for a year or two.

What a regiment of gulls!—young birds mixed with those in adult plumage,—with "old Mows," as Broadback calls them. "Shute them? Might as well shute at a Grinlin (Greenland) bear! Them there things, and the Danish (hooded) crows too, know when anybody have a gun, as well as what we do!"

Time passes, we return to the boat, and find the channel of "the pit" and "the harbour" inclosed between high walls of shingle sand, the mass of which is found to extend daily. All that point, from the pilots' house to its end, has been gathered by the waters within the last six-and-twenty years, and is still increasing. Before embarking, we will root up a few botanical specimens, and, for private reasons, I shall make free with this rusty piece of old iron hoop.

We are again afloat; the cockle-ground over the way is in capital order; but, get as near as we can, there are many yards between us and dry land. Broadback is overboard. A ride pick-back on that blue bale of flannel saves us wet ankles, though we will say nothing about wet feet. What painter (Copley Fielding, perhaps) could put this scene within a gilt frame? Miles upon miles of trackless sands! We will stick up this bit of drift-wood, as a land-mark, in case,—who can tell? Sudden fogs, or spring-tides, might puzzle us to find the boat.

But is this the famous cockle-ground of Norfolk? Where are the cockles? None are to be seen. They are here, nevertheless. Now for the use of our old iron hoop. We will give it a preliminary flourish, for luck. Who wants shaving?

To business! Half-a-mile off is a fellow stooping at work. Let us join him. In one hand he has a wooden cockle-rake,—a short-handled thing, set with iron teeth; with the other he picks up the cockles, and throws them into his basket. Ah! I see! The cockles lie beneath the sand, embedded in it, at a depth of from half-an-inch to an inch-and-a-half. This is a British California, and these are the diggings. Neither gold, nor cockles, grow on hedges: both have to be worked for. We have brought our basket: the iron hoop shall be fairly divided. You take one half, and I the other. Now scrape away. Bravo; this beats the rake! That fellow loses many a nice one between his rake's teeth. The old ladies from Stiffkey prefer iron hoops to rakes. Another handful of cockles; and here, another! We shall fill the basket. This man only happens to be out cockleing because he has nothing better to do. The regular female professionals are not here to-day, because the carriers' carts (departing twice a week) have all left this morning; otherwise you would have seen a numerous coterie, with succinet drapery, mahogany legs, and incessant clack; still they have a discipline, and a fair-is-fair sort of feeling among themselves. They think this sport, in all possible weather, no hardship; nor grumble at carrying a bushel of cockles two or three miles. Shut them in their cottages, and keep them incessantly to the loom, or the needle, and they would soon pine and die, if they did not go mad.

There; we have filled the basket, a good peck-and-a-half, and have earned a shilling, at eight-pence the peck. The good folks here make three "culls" of their gathering, and

sell the best at three-pence a quarter. Ours are a beautiful sample, clean, not gritty, large, well-flavoured. A man from the next parish discovered this particular "digging" about three weeks ago, and made a fine harvest, till the Stiffkey folks found out his secret. But the tide is flowing, and will carry us up-channel. Time to be off: it is getting dusk, and coming on "roky." Those are not ships, as seen through the misty air, but ghosts of them. Darker and darker, and no moon. The keel of the boat scrapes against the oyster "lays," but does not stick, the tide bears us upwards and onwards so fast. There shines the light of a forge, to serve as a beacon. I wonder how Broadback can find the way, amidst those intricate creeks and mud-banks. "And I," says Broadback, "wonder people are not afraid to travel by night through those lonesome roads, and lanes, and woods." And here we are at last at Blakeney: the day's excursion is ended. I feel a vacancy about the region of the stomach that will not be easily filled up. Afterwards, we will amuse ourselves by roasting cockles for dessert.

South of the Wash, the sandy dunes of Norfolk, called "Meals" and "Marram Banks," are the only places on the east coast of England where there is any chance of catching the sheldrake in the act of nesting; and that chance is yearly becoming less and less, solely from the intrusive curiosity of man. For in front remains the sea, and behind, at present, the salt-marshes; while the rabbits are as numerous as ever, to scoop out the required excavations. The sheldrake is no excavator, and yet it will have a cavern for its nursery. How it arranges matters with the rabbit, of whose house it takes possession, is not so easy to guess as in the case of the pufins, who are equally impertinent in other warrens. They have a bill that would furnish a sharp answer to any rabbit that undertook to remonstrate too obstinately at the mouth of his hole. The want of this underground retreat is one reason why sheldrakes so rarely breed in confinement. They have been successfully tempted by artificial burrows near the water's edge; and a hollow tree let into the bank, forming a sort of blind tunnel, or choked-up drain, has proved irresistible. The darkness seems to be one of the conditions which pleases them; for a tame pair, not being able to find any subterranean hiding-place for their eggs, deposited them under the thickest obscurity of some clipped yews. By attending to these natural requirements; by now and then giving the old birds a treat of small cockles, mussels, and periwinkles; and by letting their young have a daily ration of fresh sea-fish chopped fine; it may be expected that this very striking bird will be reared more frequently than it now is, in the tiny lakes which give so pleasing a charm to our lawns and our shrubberies.

D.

TO CORRESPONDENTS.

VINES (*Omega*).—We are not aware of any work which treats specially of vines in pots. Before answering your questions safely, it will be necessary to know the age of your plants, the diameter of the shoots in their thickest part, and the size of the pot they are in. This obtained, we will give a satisfactory answer.

APRICOT AND QUINCE (*H. M., Herts.*).—Your *Breda Apricot* is not an uncommon case. We had one as large as an apple-tree, which stood for fifteen years without producing a crop—indeed, it seldom set any; but it was too far north (Cheshire). Hertfordshire should produce one. Your "not very free exposure" means partial shade, and this will not do. We would remove it to where it gets every hour's sunshine, and plant it on the ground level, with only a foot of soil beneath it, and that plain loam; no manure. It must not grow strong; and succulent wood should be pinched in from June and July. You may prune away all the coarse young wood on removal. The only one we ever saw cultivated with high success as a tree, was, like yours, at Hampton Court, at the Royal gardens. Thirty-five years since, we have seen this tree laden with fine fruit, and once partook of a tart from the produce; this was excellent. Your Quince that is mildewed, and has ceased to bear, must have a thinning, and receive the sulphur mixture when at rest; also top-dress with old vegetable matter. The Quince is very liable to this mildew. Prune your nuts heavily, and root-prune them.

ERRATUM.—Page 28, line 36, for *monstrous* read *monotonous*.

SEVEN HARDY CLIMBERS FOR GREENHOUSE, AND CONTRASTING IN COLOUR (*N. S. E.*).—*Passiflora racemosa*, purplish; *Bignonia capensis*, yellow; *Passiflora corulea*, blue; *Kennedia Marryatta*, scarlet; *Mandevilla suaveolens*, white; *Tacsonia pinnatifidula*, rose; *Bignonia cherere*, reddish-dull-orange. These will do planted outside of the house, but the roots and stems (as much as is outside) must be protected, the former with litter, the latter with square boxes set against the front wall, filled with sawdust, and capped from wet. They will succeed also in pots or boxes inside the house, but they will grow more rampant in the border.

TWO PLANTS FOR THE BACK WALL OF A GREENHOUSE (*Ibid.*).—You have not said for what purpose. If merely to keep green, try *Cissus*

pentaphylla, and *C. elongata*; if light would reach the wall sufficiently, train *Acacia armata* in one division, and *A. grandis* in the other; or make half *Cactus speciosissimus*, and the other *speciosus*, but they must be dry in winter.

ERICA BICOLOR (M. A. B.).—This produces colourless flowers, and yet the plant is healthy, and well treated. We cannot say what is the cause; perhaps the plant is rather vigorous. Restrain water, just to keep it safe, and see what that will do. We have seen a similar effect produced by water from a pond, in which there was a considerable proportion of decomposing vegetable and animal matter. Use rain water, if possible.

GOLDING'S IMPROVED HIVE (C. W.).—I generally use a bung of cork (when I can procure any so large) for the top holes to all my hives, whether of wood or straw; but there is no need to despise a bit of slate or wood, or anything that may come first to hand suitable for the purpose of covering the holes effectually. I never ventilate my hives in winter, but think it better to keep the bees as snug as possible. My large Golding's hives (of one bushel, corn measure, for permanent stocks) are quite large enough to keep up a supply of as much pure air as the bees can require.

—A COUNTRY CURATE.

AGE OF YOUNG BEE BROOD (Mary).—If your correspondent can procure a copy of the second edition of "The Honey Bee," by Dr. Bevan, she will, at page 398, find a plate exhibiting a piece of honey-comb, and giving very accurate representations of young worker bees of every age, from the first hatching of the eggs at three days old, to the ceiling up of the cell. The eggs are long, whitish, thread-like, or worm-like objects, and when once seen cannot be mistaken. It is not good to use old brood-comb, the bees find it difficult to work up into royal cells. The newer the comb the better. I always get pieces of fresh comb, containing both eggs and brood.—A COUNTRY CURATE.

SOIL FOR ROSES (Subscriber).—The nearest idea we can give you of the right soil for Roses of the *Noisette*, *Bourbon*, and *Hybrid perpetuelle* classes, is this: The same soil that will grow the best onions is the best for these Roses; that soil ought to be manured for Roses, as for onions, with the best rotten manure. Any garden "man," or any "odd" man near you, could tell from this if your soil is suitable. Twenty inches or two feet would be better than less depth if the bottom is dry or drained. If it is not, and is sour and wet, a foot deep is quite enough. For the *Tea-scented Roses*, we would use as much fresh light loam as we could get, chopping up the turf with it, and to every four barrow-loads of it add one barrow-load of half-dry rotten dung. We would mix all this before filling the bed, which is a better way than digging in the dung. No one can tell the actual strength of *liquid-manure*. Use it weak and often is the only safe rule. It is weak when it will not kill grass or dock leaves, or any rough weeds, and after mixing a lot, one can always prove it that way.

FLOWER-GARDEN PLAN (Michel).—Some day or other we may engrave your plan, on account of the novelty of the design. The colours are put in beautifully and artistically, but the plan is all but impracticable. There are seven colours given in each of the end groups, four of which are collected together in one sharp point, a thing that can never be done in practice. The *Marigold* and *Anagallis* will never associate for one side, nor be in proper character with the fine shades of *Verbena* on the opposite sides if they did. The gradations of heights in plants must be as much considered as the colours in a regular figure. A plan or garden that admits of all the plants being of the same height is less dignified than one in which different heights can be arranged with good effect; the latter is by far the most difficult to design.

GERANIUM CUTTINGS (British Seaman).—From your log, we say positively that you will not be wrecked, but the cargo will not come all safe to port. You weighed anchor too late in the season for this. Keep cutting away all leaves that droop, and pick off every black speck as soon as perceived; be sparing of the watering-pot, and raise the temperature just ten degrees. Geranium cuttings made very late in the autumn (October) would be safer on a shelf, high up in the greenhouse, than in a hot-pit of 50° an hour after breakfast. We put in nearly as many pots of cuttings as you (100), late in October, and put them on a very dry shelf, under glass, up high above pots and kettles, with a free current of air, and we expect about seven or eight out of every ten of the cuttings to live; and if they are rooted by the middle or end of February, it is all that we expect and wish for. Hotbeds are awful places for unstruck cuttings in November. *Wood lice* do little or no harm to Geranium cuttings in winter. A selection of bedding Geraniums will be given before you can want them.

CARNATION AND PICOTEE SOIL (G. W. C.).—You say your soil in which you have hitherto grown Carnations, Picotees, and Pinks, is light, and rather inclined to be sandy, and that you have purchased them at times, but have nearly all died. Your soil is too light, and there should be no sand in it. Procure some virgin loam, make your bed of it, with the addition of about one-eighth very well-decomposed hotbed manure. Plant the Pinks now, and the Carnations and Picotees in spring, about the end of March, and attend to the instruction in the Monthly Calendar. Are you quite sure you have no wire-worms in your soil? They are very destructive to these plants. We never recommend dealers.

ARNOLD'S VICTORY GERANIUM (An Amateur).—This was a mistake; it should have been *Arnold's Virgin Queen*.

ROSES (Zadkiel).—You, or a namesake, used to predict the weather, and we predict, that if this should be a very hard winter you will lose nine out of ten of your newly-budded roses that had grown an inch by the middle of October. You must not ask for our sympathy, for you have rushed against a cross firing on the subject of budding roses this very season; but the loss will not be lost on you. When you had next year you will attend to our directions, and not cut back, or even stop, any of the shoots at the time of budding.

CUCUMBERS (Ibid).—Go on and prosper with your new house, the symptoms could hardly be better: house at 80°, soil at 90°, with fine, damp atmosphere; plants looking healthy, and fruit twelve inches long, and growing. What could Mr. Latter himself want more than that? If you find the edges of a single leaf damping from this moist atmosphere, give more air, and throw something on the glass at night, and that will lessen the drips.

TOM THUMB (A. S., 16th Oct.).—Out of all your letter we can only read "Tom Thumb," and "No. 1, 2, and 3." Pray write to us plainly.

SALVIA PATENS (X. Z.).—If you do not want the pots this winter, you had better leave the roots in them, and if you put them in an outside they will dry slowly, without any more trouble. They will also stand exactly the same treatment as potatoes in winter. You might pit them, or house them, or keep them a little moist, or nearly dry. The surest way to get rid of the worms is to turn out the balls gently on the palm of the left hand, and hand-pick them from the balls. Do not, on any account, resort to the common nostrums for poisoning them in the pots.

WINTERING GERANIUMS (Shylock).—If you will refer to page 53 of our last number you will find a mode exactly suitable to your case.

CINERARIA SOWING (B-le-B).—Sow the seed as soon after it is ripe as you can.

HOLLYHOCKS (T. J. C.).—We cannot put in such a proposition.

COW DISEASED (G. T. H.).—The case is too critical for us to advise you. You had better consult some regularly educated veterinary surgeon. What your man says is nonsense.

FUNGUSES (H. L.).—We believe those you sent are poisonous. They are too dangerous to try experiments with.

VULCANISED INDIAN-RUBBER.—J. M. wishes to be informed how he can make a cement that will fix Vulcanised Indian-rubber to wood, glass, or leather.

FORGET-ME-NOT.—If *Ellen*, or any other of our subscribers, will forward their address, with two postage stamps, to *F. Brett, Esq., Potter's Bar, near Barnet*, he will send them a root of this free by post.

OUR VOLUMES (T. G., Dominica).—Our first volume commenced with the first Thursday of the October of 1848, and concluded on the last Thursday in the March of 1849. Our second volume commenced on the first Thursday of April 1849, and ended with the last Thursday in the September of that year. So have the volumes continued to divide the year ever since. You can have indexes for each two volumes that so comprise twelvemonths.

POLAND FOWLS AT DOMINICA (Ibid).—Our correspondent says he thinks he is the first person to introduce these fowls into the West Indies. They were shortly attacked with what he considered a severe cold, affecting chiefly their eyes, and partially blinding some of them, but the birds have bred, and we hope to hear from him how the chickens prosper. The disease was not a cold, but the roup, an inflammation of the head and eyes, caused by the confinement, filth, bad feeding, bad water, and exposure to weather on board ship. A daily pill the size of a pea, made of two parts powdered gentian and one part hydriodate of potash, is the best medicine. Good food and cleanliness are essential additions.

POTATO PLANTING (R. K.).—On the Cotswold Hills, and in a soil and exposure favourable to potato culture, we would still plant no later varieties than *Hoptown Earlies*, *Ash-leaved Kidneys*, and *Rylott's Flour-balls*. Keep your sets as free from sprouting as possible, until you wish to plant them.

BACK NUMBERS (Alpha, Birmingham).—None are now out of print. All have been reprinted.

WHAT IS A PURE BREED OF FOWLS? (Investigator).—This is a question not so difficult to answer as it may appear. Our correspondent asks, "Whether a cross between pure-bred Dorkings and a Game cock would revert to the original type of Dorking in two generations? That is to say, would the cross between Dorking and Game, bred again with pure Dorking, produce fowls which could be called true Dorkings?" We think they would, otherwise one of the most efficient modes of improving our breeds of domesticated animals would be closed. How common is it to infuse courage and substance into our breed of Pointers by a cross with the Hound; and how equally common to derive fineness of bone, depth of carcase, and other desirable points, by an intermixture of our breeds of oxen. Yet the calf of a Short-horn cow, if it retained all the characteristic points of its variety, would be classed as a Short-horn, without any reference to the bull that was its grand-sire.

NAMES OF PLANTS (Rev. R. M. E.).—Your annual is *Coreopsis Drummondii*, in *The Cottage Gardeners' Dictionary*, but also known as a *Calliopsis*. (*Hester S.*)—The Conifer is not Cedar of Lebanon, but the Hemlock Spruce Fir, *Abies Canadensis*. Nothing certain is known about the *Hamony*. We will say more about it, however, soon. (*T. F. J.*)—Your annual is the *Centurea cyanus*, varied a little in colour; the second is not a *Lycopod*, but *Saxifraga elongata*, or Long-stalked Saxifrage. We do not recognise the orchid from the leaves, but will enquire. (*B. H.*)—1. *Cineraria umelloides*. 2. *Statice mucronata*. 3. Too small a specimen. 4. *Sedum Sieboldii*.

CALENDAR FOR NOVEMBER.

FLOWER GARDEN.

ANEMONES, plant for succession bloom. **AURICULAS** and **POLYANTHUSES**, put under shelter (See October). **BULBOUS ROOTS**, finish planting in dry weather; or pot for latest forcing, and for plunging in flower-beds, &c. **CARNATION** layers, finish planting and potting; secure the pot at once from rains. **CLIMBERS** of all sorts, plant, prune, and train. **COMPOST**, prepare and turn in dry weather. **CROCUS**, pot large lumps from the borders for forcing. **CHRYSANTHEMUMS**, against walls or fences, secure from frost. **HALF-HARDY** bulbs in borders, secure from frost and rain by a boarded covering. **DAHLIAS**, cut down after frost, and let roots remain as long as it is safe; when taken up, dry them in open sheds, &c., before storing, where frost and damp cannot reach them. **DRESS** the beds and borders, and put mark-sticks to bulbs and other roots, to guide you when digging. **EDGINGS**, plant. **EVERGREENS**, finish planting, b. **FIBROUS-ROOTED PLANTS**, finish dividing and planting, b. **FORK** over borders, &c. **GLADIOLUS**: all the old sorts may yet be planted; most of the new do better planted in spring. **GRASS**, cut very close the last time; keep clear of leaves; and roll. **GRAVEL**, weed and roll. **HEDGES**, plant, clip, and clear at bottom. **HOE** and rake shrubberies, and bury the leaves, &c. between the plants. **HOLLYHOCKS**, finish planting. **LAYERING**, perform at intervals, if fine weather, till March. **LEAVES**, gather for compost, &c. **MARVEL OF PERU**, take up and store like dahlias. **MULCH** round trees and shrubs lately planted. **PLANT** perennials and biennials (See October). **PLANTING**, deciduous shrubs and trees, perform generally, and finish as early as

practicable. **POTTED PLANTS**, for forcing, plunge in the earth of a well-sheltered border facing the sun. **PRUNE** shrubs and trees generally. **RANUNCULUSES**, plant for earliest bloom. Seedlings of them, in boxes, &c., remove to a warm situation. **WEAK ROSES**, prune without delay; very strong ones, delay pruning till March; tender ones, secure from frost with moss, fern, &c. **SHRUBS** of all kinds, plant, stake, and mulch. **SUCKERS**, from roses and other shrubs, separate and plant. **TIGRIDIAS**, save from frost as long as possible; should not be dried till January or February. **TULIPS**, finish planting, b. D. BEATON.

GREENHOUSE.

AIR, admit rather freely in dry weather. **AZALEAS**, for blooming early, keep in the warmest end of the house, and they will not lose many of their leaves; if the buds are well set and prominent, a few may receive the heat of a plant stove, to bring them in by Christmas; those once forced will come earlier of their own accord again. Those for flowering in spring and early summer keep as cool as possible, so that the temperature is above 35°. **BULBS**, such as hyacinths, tulips, narcissus, &c., pot for spring flowering, and so manage them that roots shall precede flower-stems. **CALCEOLARIAS**, keep growing slowly, in an airy, moist atmosphere; seedlings, pot off, and prick into pans; cuttings of shrubby ones may now be potted, and cuttings may even be put in in the beginning of the month, in a cool, moist place. **CAMELLIAS**, finish setting in; and the late ones may have their buds thinned, if necessary; the earliest will now be swelling, and a little cow-dung water, cleared, and not too strong, will do them good; these should be placed with the forward azaleas. **CINERARIAS**, encourage the forwardest to grow in a moist, gentle heat; keep those for spring and summer just moving. **CLIMBERS**, however beautiful, cut back to give light to the other plants. **CHRYSANTHEMUMS**, remove incipient roots from the axils of the leaves on the main shoots; thin the buds where too thick; encourage with manure water; and if not all in doors, have protection ready. **DAMP STAGNANT AIR**, avoid. **FIRES**, light in frosty and foggy weather, that air may be given; but give artificial heat during the day, rather than at night, unless the frost is very severe. Choose a sunny day, if possible, to light your first fire, as your flue, &c., will be more easily dried: it is no joke to be fixed in a stock-hole behind a fire that will not burn. **FURNACES** and **FLUES**, clean out previously. **HEATHS** and **EPACRISSES**, keep in the airiest part, especially the former. **GRNISTAS**, **CYTISUSES**, **CORONILLAS**, &c., syringe in a sunny day, and aid with manure water, to cause the bloom to open strongly. **GERANIUMS** or **PELARGONIUMS**, encourage the old plants with a good position; train into the desired shape. Nip any luxuriant shoot, so as to equalise the strength; keep fresh potted ones just moving. **GOMPHOLOBIUMS**, *Platylobium*, *Chorozenus*, &c., place in double pots, that they may be more uniform in moisture, as extreme dryness and extreme wet will alike be their ruin. **PLANTS**, keep clear from dirt and insects, by washing and fumigation. **TEMPERATURE**, keep from 40° to 45° at night. **WATER** only when necessary in dull weather; little will be wanted, unless for plants swelling their flower-buds; for these use water warmer than the air of the house. A slight dusting with the syringe over the foliage will be serviceable in a sunny morning. **CLEAN** pots, paths, stages; tie, train, and fresh label in bad weather.

R. FISH.

FRUIT-FORCING.

CHERRIES in tubs, &c., protect roots. **CAPSICUMS**, dry off at root to ripen them. **CUCUMBERS**, afford necessary heat, not below 70°, with air-moisture and all possible light. Early forcing prepare for. **FIGS** for forcing, get to rest; protect pots or boxes, as also branches. **FLUES**, clean all and repair. **INSECTS**, continue the warfare against, also preventive measures. **MUSHROOM-BEDS**, provide succession; spawn when down to 75°; sprinkle beds where the Mushrooms are coming through; keep a moist air. **MELONS**, sustain 75° bottom-heat, 70° top-heat, with abundance of air; fumigate if infected. **NECTARINES** and **PEACHES**, prepare for early forcing, by using the wash so often named in this work, pruning them previously. **PINES**, in dung-pits, improve declining heats; 60° to 70°, with liberal ventilation. **Pines**, late fruiters, 5° more; air in moderation. **REPAIRS**, carry out directly in all houses. **REST** fruits for forcing, plunge and protect wood. **STRAWBERRIES**, in pots, plunge and protect. **VENTILATION**, attend well to during dull periods. **VINES**, for early forcing, as *Peaches*; if roots outside, protect border directly. **Vines**, in fruit, fire occasionally; ventilate freely; keep very dry, and use scissors weekly.

R. ERRINGTON.

ORCHARD.

BORDERS, autumn-dress. **BUDS**, cut bandages off. **CHESNUTS**, gather. **DRESS** to KILL INSECTS as soon as pruned. **FRUIT**, gather all remaining. **FRUIT-TREES** of all kinds plant. **FRUIT-ROOMS**, ventilate freely. **FRUIT-STORES**, pick over. **INSECTS**, wage war against, at every opportunity. **MEDLARS**, preserve. **MULCH**, apply to newly-planted trees. **NUTS**, remove suckers from. **NAILING**, proceed with, in order to expedite spring business. **PRUNING**, perform in the following order: 1st. Bush-fruit, then Cherries, Apples, Plums, Peaches, Vines, &c., and ordinary Pears, reserving choice ones, Apricots, Figs, &c., until spring. **PROTECTION** for blossom, lay by from shrubbery or wood prunings. **PLANTING**, proceed with, all but Figs and Vines. **RASPBERRIES**, plant suckers from, and prune. **ROOT-PRUNING**, perform immediately. **STAKING**, see to. **STRAWBERRIES**, remove rubbish between rows, and manure, but cut not the foliage. **STATIONS**, prepare. **TRAINING**, carry out betimes. **TOMATOES**, ripen before the fire. **TOP-DRESSINGS**, apply. **WALKS**, turn or clean for the winter. **WEATHER**, provide in-door's work for a bad season, such as labels, stakes, training pegs, &c., and grind your bill-hooks, and file your hand-saws.

R. ERRINGTON.

ORCHID HOUSE.

AIR will seldom be required during this month; keep the air inside much cooler, because most of the plants ought now to be in a state of rest. **BASKETS**, plants in, should only be syringed; they ought to be so placed that the drip from them may fall into the walk. **DIVISION**: such plants as *Stanhopeas*, *Gongoras*, and *Acropcia*, may be divided this month, with a view to increase them; give these no water till they start into growth again. **HEAT**: the thermometer in the warmer house should be allowed to fall to 58° in the night, and never exceed 70° by day; 65°

without sun will be sufficient. **POTTING** will be required occasionally; even at this untoward season of the year some plants will grow, and, therefore, must be potted, because if delayed the young roots will begin to push, and then it is difficult to pot without breaking them. **REST**: keep all the plants possible at rest for the next two months; the means are a cooler and drier atmosphere, and no more water at the root than is absolutely necessary to prevent the pseudo-bulbs perishing. **SYRINGING** will be necessary to plants on blocks two or three times during the month. **WATER**, apply sparingly, except to plants growing; to these a larger quantity may be given. T. APFLEBY.

PLANT STOVE.

AIR will still be necessary to this department; give it early in the forenoon, and close the opening by two o'clock. To sweeten the air, light the fires early in the morning, and give air accordingly; this will allow a large body of fresh air to enter the house, which will displace as much foul air. **CUTTINGS** of stove plants should all be potted off early this month if rooted. **BULBS** should now generally be at rest; keep them dry and moderately cool, to prevent a too early excitement. **FORCING-FLOWERS** for this department should be commenced slowly, early in the month, such as *Azaleas*, *Lilacs*, *Laburnums*, *Rhododendrons*, *Roses*, &c. These will flower in December or January. **WINTER-FLOWERING PLANTS** will now be showing their flowers. They should have a moderate supply of water, and occasionally a watering with weak liquid-manure. Keep every part of the stove perfectly sweet and clean; remove all decaying leaves as they occur; stir up the surface of the soil in the pots, to prevent moss and weeds from appearing. In this month, a supply of the different soils, manures, and vegetable mould, should be procured. T. APFLEBY.

FLORISTS' FLOWERS.

ANEMONES may yet be planted, excepting the finest double ones. **AURICULAS** and **POLYANTHUSES**; no delay must take place in putting these into winter quarters, if not already done. Scatter occasionally amongst the pots a layer of very dry ashes, which will absorb the moisture. **CARNATIONS** and **PICOTEES**, finish taking off the layers, and potting them; place them in cold frames, giving plenty of air every day. **DAHLIAS**, cut down when frost-bitten, and cover the roots with a small billock of coal-ashes, or take them up at once, and reverse the roots, to allow the moisture to run out of the hollow stem. Number every root, and put them by in a dry, cool place, where no frost can reach them. **FUCSIAS**, done blooming, prune in, and give no water to, for a month. **HYACINTHS**, finish planting, both in pots and beds. **IRISES**, both *Spanish* and *English*, plant in a rich soil and open situation. **NARCISSUS**, pot and plant out in the beds. **PINKS**, plant out early; fasten firmly, to prevent the frosts from drawing them out. **RANUNCULUS-BEDS** prepare. *Turban variety* plant in beds and pots, the fine-named varieties do not plant till spring. **TULIPS**, plant on or about the 10th of the month; choose a dry day for doing this. **VERBENAS**, take up and pot, dressing-off the straggling branches; their cuttings shelter from early frost. All **FLORISTS' FLOWERS** in **FRAMES** and **PITS** keep moderately dry, clear of weeds, and decaying leaves. Search for **SLUGS** and other vermin daily. T. APFLEBY.

KITCHEN-GARDEN.

ARTICHOKES, winter dress. **ASPARAGUS-BEDS**, dress; attend to that in forcing, and plant in succession. **BEANS**, plant a good main crop toward the end of the month. **BEEF** (Red), dig up for storing. **BROCOLI**, lay down or remove to other warmer situations with good balls of earth; take care not to injure their leaves. **CABBAGES**, plant or prick out into nursery-beds. **CARDOONS**, earth up, b. **CARROTS**, dig up and store, b.; leave or plant out for seed. **CAULIFLOWERS**, prick out in frames, &c., for winter protection, pay particular attention to airing in all fine weather, both hand-glass crops and otherwise. **CELEBY**, earth-up in dry afternoons, having the earth all forked up previously. **COLE-WORTS**, plant. **COMPOSTS**, prepare, and always have a supply in the dry for immediate use. **CUCUMBERS**, attend to in forcing. **DRAINING**, attend to where required. **DUNG**, prepare for hotbeds. **EARTHING-UP**, attend to. **ENDIVE**, tie up for blanching or otherwise; pay particular attention to protection. **GARLIC**, plant. **HERBARY**, clean, &c. **HORING**, attend to; on a fine afternoon never lose a favourable opportunity for this or any other kind of work. **HORSERADISH**, dig up, and lay in the prime for use, and replant. **HOTBEDS**, make for salading, &c. **JERUSALEM ARTICHOKEs**, dig up and store. **LEAVES**, continually collect into some corner for future use. **LETTUCES**, plant in frames; attend to those advancing. **MINT**, plant; force in hotbed. **MUSHROOM-BEDS**, make; attend to those in production. **ONIONS**, in store, look over; (Potato), plant. **PARSLEY**, plant some in a frame for use in snowy weather. **PARSNIPS**, dig up and store, b.; leave or plant out for seed. **PEAS**, of the best early kinds, may be sown toward the middle or end of the month. **POTATOES**, attend to those in store, or dig up, should any remain out. **RHUBARB**, clear away decayed leaves, and top dress; also pot off any number of plants that may be required for early forcing, to bring into the forcing structure as wanted. **RADISHES**, sow, in hotbed. **SALSAFY**, dig up and store. **SCORZONERA**, dig up and store. **SEA-KALE**, pay particular attention to the removing of all the decayed leaves, &c.; top-dressing, covering up with fermenting materials, or other modes of forcing. **SEEDS**, dress and store. **SHALLOTS**, plant, b. **SMALL SALAD-ING**, sow; sow in hotbed. **SPINACH**, thin, earth-stir, and keep clear of decayed and fallen leaves. **THINNING**, attend to. **TRENCH**, ridge, &c., vacant ground. **TURNIPS**, attend to thinning-out, or hoeing the late sown crops, and should the weather be inclined to set in very severe, any number of turnips that are full grown may be taken up, and stored for winter use. Spading-in is often better than the hoe. Always **COVER-UP** a little earlier on the appearance of frosty nights. Also look over your **BROCOLI** quarters of a frosty-looking evening. See if any are fit to cut, or if their leaves need to be broken down over the heads as a protection. T. WEAVER.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last twenty-five years, the average highest and lowest temperatures of these days are 51.8° and 37.6° respectively. The greatest heat, 63°, occurred on the 6th in 1834; and the lowest cold, 20°, on the 3rd in 1845. During the period 91 days were fine, and on 84 rain fell.

LONG TUBED-FLOWERED OXYANTH.

(*Oxyanthus tubiflorus*.)

THIS is a handsome stove evergreen shrub, about three feet high, from Sierra Leone, having white starry, fragrant flowers, with long tubes, as expressed by its names, *Oxyanthus* being derived from *oxys*, sharp, and *anthus*, a flower, referring to the sharp-pointed or starry divisions of both the flower and flower-cup, *alias* calyx. It is figured in *Andrews's Botanical Reports* as *Gardenia tubiflora*.* The genus consists of plants having flowers more or less tubular, but there is a marked difference in the extraordinary length of the tube in the present species, which justifies the application of the specific name, *tubiflorus*. The genus was founded, some years since, by De Candolle. The present species was received by the Earl of Derby direct from Sierra Leone, and was sent by him to Kew, where it flowered for the first time in the July of 1851. It had previously been cultivated at Kew, but erroneously, as the *O. speciosus* of De Candolle. *Leaves* unequal sided, opposite, about four inches long, pointed-reversed-egg-shaped, smooth, almost stalkless; *flowers* in a single cluster, on very short stalks, from between a leaf and the branch; *corolla* greenish-white, six inches long; *stamens* at the mouth of the tube; *stigma* projecting out of the tube. It belongs to Pentandria Monogynia of Linnæus.

The genus belongs to a section of the Cinchonads, which is named in Latin after *Gardenia*, and may be translated *Gardeniads*. Its nearest relationship is with *Posoqueria*, but

* It is *O. tubiflorus* in *Botanical Magazine*, t. 4636.

is not far removed from *Gardenia*, and *Randia*. Formerly, and even at the present day, the plants included in this extensive order are called Madderworts (*Rubiaceæ*), by some able botanists. The natural differences between the true Cinchonads and the real Madderworts are so obvious, however, that the young gardener can point them out at first sight. All the Madders have square stalks, and the leaves are in whorls round the stalk, without any stipules. The Cinchonads, on the other hand, have not a single plant among them with a square stalk, out of the 2,500 species enumerated as such, nor one having the leaves produced in whorls, and every one of them have stipules; the stipules themselves being placed differently in Cinchonads from all other plants, that is not immediately under the foot-stalk of the leaf, but intermediate between one pair of leaves, and the next pair; or, as botanists say, interpetiolarly. Almost all the Madders are as mere weeds to gardeners, while the great majority of Cinchonads are among his best stove plants, as *Ixora*, *Bouvardia*, *Gardenia*, *Rondeletia*, *Hindsia*, *Pentas*, *Manettia*, and many more such. B. J.

Propagation and Culture.—All the best flowering plants in this large order are natives of countries lying within the tropics, and, therefore, require stove heat in this country, and of them it may be said, more than of other tribes, that, as long as they are in the nursing state, the temperature of a close pit, with a brisk bottom-heat, derived from stable-dung, or the old hotbed system is more necessary for them, and more congenial to their nature; and also, that while in this progressive state, they require more peat in the compost than most woody stove plants. With these general rules before the propagator, he takes cuttings of *Oxyanthus tubiflorus*, from the tops of the side-shoots, early in March; plants them close to the sides of a small pot filled with a compost of one-half peat and one-half sand, with an inch of silver sand on the top; and when the pot has had time to drain, after a liberal watering, he places it within another pot, one size larger, filling the space between the two pots with any light compost, finishing with a little sand on the top, to receive his bell glass, which must rest about half way between the two pots. If all goes on as it should, he expects to see his cuttings rooted in six weeks, but a week or two, more or less, will not damp his ardour, if his cuttings do not damp off meanwhile, and to save them from that, he takes off the glass occasionally, wipes it dry, and sees that the sand is neither too wet, nor over dry about the cuttings. At other times, he merely waters the outside of the bell-glass, which will trickle down in the outside pot, and so keep the inner pot and the cuttings sufficiently damp to insure safety, and the emission of roots. When the cuttings are well rooted, he shakes them gently out of the pot, and using two-thirds peat, and one-third sand, he pots them singly into little pots, but instead of placing his little plants in the middle of the pot, old-blue-apron like, he puts each of them in quite close to the side of the pot, and this allows more space for the tender roots, and they will not be so likely to get broken. After a gentle watering with warm water, he plunges the pot again in the hotbed, and puts a small hand-glass over them to insure a speedy growth. A few days after this, he tilts the hand-light on one side, to inure his nurslings to the air by degrees. In a few more days the hand-light is left off at night, and put on after breakfast time, and the first cloudy day he leaves the hand-glass off altogether. A son born to an Empire

could not be more tended to than they are all this time; but it is not more than is necessary, for the nursery is the proper place to lay the foundation of future prosperity, both for plant and heir. As soon as the little pots are filled with roots, then comes another shift, and this is the right time to put the plant in the right place—the centre of the pot—which is a simple move, only to place the ball more to one side of the new pot. The compost is a little stronger, and more stimulating this time; one-third peat, one-third sandy loam, and the other third made of sand and leaf mould.

If all this has been got through by Midsummer, the plants may require another shift before the end of July, but it is always more safe for seedlings, and for young

plants got from cuttings, to begin the autumn with them a month earlier, without a shift at the end of July, than to face the winter with them in pots not well filled with roots and wood in an unripe condition. Therefore, on the whole, let gardeners risk as they may—if they kill two to save one plant, who cares—but let the amateur take my advice, and be content with less growth the first season, and more security for the next. After the first year, our *Oxyanthus* will rank with a general assortment of young promising stuff, requiring about one-third peat, and two-thirds good friable loam, a few charcoal bits, and a little sand, also weak liquid-manure, now and then, and frame-culture, with stopping of shoots, so as to bring up a sure foundation for the future specimen.

D. BEATON.

HOWEVER much some of our correspondents may object to our advocacy of the Potato as a main crop, we must still pursue our course; and we are firm in our resolve to persevere, for many reasons, of which one or two of the most prominent will, perhaps, be accepted as a sufficient justification.

In the first place, the declaration of one gentleman, with whom we conversed the other day, bears testimony to a fact of far greater importance than the words, at first, may seem to convey:—"I do not care for my dinner," he said, "unless potatoes are part of it." It is not an exaggeration to say, that to three-fourths of the population of our islands this vegetable is similarly acceptable. Nor is it a mere consideration as to whether this or that plant affords a food most agreeable to the palate, though even that is important; but the fact is notorious, that, by the best of management, you cannot grow of any other crop so large an amount of nutriment upon an equal space of ground.

The Potato being so generally acceptable to the palate, and being so very productive, it has become, as a matter of course, a crop of most extensive cultivation. The amount of this cultivation has been endeavoured to be ascertained in various ways, and the following are some of the facts ascertained:—

In 1847, Parliament obtained from three unions, selected as fair average examples, returns of the amount of acres devoted to the culture of the various usual crops. In *England*, out of the 21,756 acres in Hartley Witney and Basingstoke union, 236 acres were occupied by Potatoes. In *Scotland*, in the county of Edinburgh, or Midlothian, of 176,874 acres, 6,625 were growing the same root; and in *Ireland*, in the Balieborough union, comprising 86,324 acres, the Potato occupied 11,492. If these, added together, are a fair average of the United Kingdom, then more than one-fifteenth of its surface is occupied by the Potato.

In the same year, Parliament obtained from the constabulary of *Ireland* a further return of the total of its acres then under Potatoes, and the returns showed a gross amount of 284,116 acres, producing 2,048,195 tons of their tubers. In *Scotland*, Mr. McCulloch calculates there are annually grown 200,000 acres of the same root; and he combines Potatoes, Turnips, and Rape, as occupying annually, in *England*, 2,000,000 acres, and their produce as worth, on an average, £14,000,000 sterling. We might multiply the statistical details to a much greater extent, but we will only add,

to show what is the consumption in London alone, that in the three months preceding the first week of December, there are, on an average, delivered there, from ships only, somewhere about 300,000 sacks, each sack containing one hundred-weight-and-a-half of Potatoes.

Now this is the crop, and for which no adequate substitute has been suggested, which we have been advised to abandon as hopelessly diseased. We deny this being its state, and a very few weeks ago we showed why we are of this opinion. We showed that the disease is not universal—that even one field bears a healthy crop, whilst another, with but a hedge between, produces a crop diseased; and that it is quite as frequent that one portion of the same field shall be exempt from the disease infecting the other portion. This being so, and these exemptions showing, as clearly as evidence can show, that there is a certain combination of circumstances which will secure a healthy crop, let us persevere hopefully in our endeavours to ascertain those circumstances.

In confirmation of the soundness of our view of the case, we have now before us two letters, which give practical proofs that there are varieties of the Potato not liable to the murrain that has scourged others; and that there are modes of culture which will ward off this murrain from a variety which is destroyed by that murrain, when differently treated.

The first letter is from Kintbury, near Hungerford, in Berkshire, from a very trustworthy authority, and it says:—"I want to draw public attention to a variety of the Potato called, hereabouts, the '*Kintbury Johns*,' and about Andover, the '*Foolhardys*.' It is a large, coarseish, prolific Potato, and does not boil floury; but it wonderfully avoids the blight, and has done so ever since the disease appeared. This year, which is considered the worst, it is remarkably free from the disease; and the gardener who has our garden says, that among his crops the *Kintbury Johns* have one gallon in a bushel tainted; while the *Fortyfollds*, and all other sorts, have three parts out of four bad. All the poorer people say the same thing. They do not plant it extensively, because they prefer other kinds for eating; but where other kinds will not keep, it seems to me that an inferior Potato is worth having."

If reference be made to our seventh volume, p. 297, a communication, signed H. B., *South Petherton*, will be found relative to Potato-planting, from which this is extracted:—

"It is possible that my plan may have been tried. The

object is to save seed, and give more light and air to the plants. I plant on ridges, three feet wide, one row down the centre, choosing the finest Potatoes, and placing them thirty inches apart. I flat-hoe early, and when the stalks are nine or ten inches long, they are spread from the centre, forming a circle, and the earth is pulled by hand over the middle of the plant; this process is repeated whenever the earth cracks.

"I succeeded this last year in my garden in producing from a ridge fifteen feet by three feet, 72½ lbs. of Potatoes, from six planted whole in March last. The several weights were 15 lbs., 15 lbs., 12 lbs., 11¼ lbs., 9¾ lbs., 9 lbs. Each Potato a different sort. Of the first, the *Old Guernsey*, six tubers weighed more than 6 lbs., and of the second, a pink kidney, there were not more than forty Potatoes to make up the 15 lbs. All the Potatoes were particularly fine."

We hoped to have had this year the results of a still larger experiment tried by the same esteemed correspondent. He, however, is gone from this world of experiments to that of realities; and we have this letter in reply to our inquiries:—"I have looked particularly to the experiments of the Potatoes planted by my late brother, and am sorry that I am not able to furnish you with any proofs of success of his intended mode of cultivation. Owing to his illness and inability to attend personally to them his directions were not carried out. He had planted them, on a large scale, in the field on the plain, in rows three feet wide and two feet apart, in drills; but instead of being laid after the first hoeing, and the earth brought up to the centre, they were hoed up in ridges in the ordinary way; consequently no fresh roots formed as last year, and the produce was deficient in consequence. Still the crop was equal in weight to those planted in drills of twenty-two inches in width, and much finer in sample, being all fit for general purposes, whilst at least one-third on the narrow drills were small; and although it would appear to be a great waste of ground, yet, from the above statement, it proves that the wide drills and deep earthing are most desirable. I strongly recommend to all small occupiers to adopt the mode of cultivation tried by my brother last year, as I am convinced, from what I see by the crop this year, although not carried out according to his plan, that it will succeed. I would also notice that, in this same field of several acres in which many of the labourers had their winter crop, there was not one exception in which they were not diseased and rotten to that extent as to be scarcely worth the expense of taking up. *Whilst in the deep experimental drills I do not think there was one affected.*"

We will only observe upon this that the writer is a highly intelligent, practical farmer, and one of the most extensive holders in the county of Somerset.

FORSYTH MSS.

IF SIR JOHN SINCLAIR had achieved nothing more in the course of the fourscore-and-two years of his life than gathering together and publishing his *Code of Agriculture*, his *Code of Health*, and his *Statistical Account of Scotland*, he would have left sufficient monuments of his untiring industry; an industry the more praiseworthy, because unstimulated by necessity.

He was the third son of G. Sinclair, Esq., heritable sheriff of Caithness, and was born in that county, at Thurso Castle, in the May of 1754. Embracing the legal profession, he was admitted a member of the faculty of advocates in Scotland, immediately that he was out of his nonage, and was called to the bar in England, about seven years later, in 1782, having previously to this sat in Parliament for his native county and other places. Although thus enrolled among the makers and interpreters of our laws, neither of their occupations were his favoured employments; for his heart was given to the cultivation of the soil. *Flemish Agriculture*, *Merino Sheep*, *Oil as a Manure*, the culture and uses of the *Potato*, the origin of *Cattle Shows* and *Agricultural Meetings*, and *Shell Marl* as a manure for Turnips, by turns, were the subjects of his researches, and were descanted upon by his pen. Nor were other subjects, though not strictly agricultural, if connected with the industrial produce of his native country, without receiving their share of his attention. An instance of this is afforded by the following letter, dated from Whitehall, February 19th, 1793:—

SIR JOHN SINCLAIR TO MR. FORSYTH.

It has lately occurred to me, that some of the French emigrants, who are now in this country, might be employed in a manner that would not be disagreeable to them, and would be useful to this country, *in the culture of silk*; but, from all the enquiries I have been able to make, there is little prospect of any material progress being made for some time. A French gentleman, however (one of the emigrants), the Viscount de Bruges, being thoroughly conversant in the culture of silk, it is a pity not to have some experiments tried in that branch even this year. I have sent for the eggs of the silk worm to different countries, and I beg you will be so obliging as to inform me whether there are many mulberries in His Majesty's gardens at Kensington, or elsewhere, and how many trees of thirty years and upwards, either of the *Red* or *White Mulberry*, might be found in the neighbourhood of London, the leaves of which might be either purchased or obtained this season. I am told that they abound much in the neighbourhood of Hammersmith, &c. I have also heard that Her Majesty has tried some experiments in regard to the culture of silk, the success of which you may have heard of. I shall be glad to have the pleasure of hearing from you upon this subject.

COVENT GARDEN.

Those whose field of observation does not extend beyond the smoke and din of London have very peculiar notions as to what is going on in the great world outside. They hear of frosts, and blights, and mildews, but comprehend them not; and when other men tell of this crop failed, and that community suffering, they regard the intelligence with a dim, hazy, and indistinct perception that there is something wrong somewhere, but they cannot realize it, simply because they do not see it, and have not felt it themselves. When you tell such people that apples are a short crop, and potatoes are diseased, they point to Covent Garden, and ask if there is evidence of such to be found there. "Pooh, pooh! nonsense," says one, "I never saw finer potatoes in my life; the farmers always did grumble, and always will; they *must* have something to grumble about." We confess there is some allowance

to be made for such remarks coming from such quarters, for there is certainly never any appearance of scarcity in our markets; and we know frequent instances where country produce is poured into London, and sold to be transmitted to the country again.

We have been led to make these remarks, that our readers may understand how it is we always speak of a "plentiful supply." It is an expression which we might as well discontinue; for whenever an article is in season, here it is sure to be. It matters not how scarce it may be elsewhere, it is safe to find its way to this great whirlpool of consumption, and that, too, in such quantities as would at first appear almost incredible to those who are unacquainted with such matters. Walking along Piccadilly one evening, a year or two ago, in company with a friend from the northern provinces, we met one of those immense four-wheeled waggons, drawn by three horses, and laden with *lettuces*, on its way to Covent Garden. My friend was attracted by what was to him an unusual sight, and after wondering first at the quantity, and then at the ingenious architect who could build a load of lettuces as high above the sides of the waggon, as the sides of the waggon were above the ground, he asked, "Is that all *one man's* growth?" We were, of course, a little amused at the question, which we answered by pointing his attention a few hundred yards further, where there were two more such waggons of the same article, and "all *one man's* growth," and such was this "one man's" contribution in this one article every market-day during the lettuce season. But this was only one man's. How many more such waggons passed along Piccadilly that same evening, on the same errand, we could not undertake to say; and how many more passed along a dozen of the other great metropolitan approaches, we are afraid to say. And thus it is in proportion with all other garden produce.

During the past week, then, the supply both of fruit and vegetables has been plentiful. APPLES continue to advance in price since last week's quotations. *Blenheim Pippins* are very fine, handsome, and highly coloured; when fully matured by keeping, they will, after assuming their yellow hue, be very beautiful. Some of them brought from 7s. 6d. to 8s. per bushel. *Ribston Pippins* have also been very fine, and made 8s. We were rather surprised to see a parcel of *Golden Knobs* so early; the usual time for them to make their appearance being about Christmas. *Kentish Broadend*, a good kitchen apple for present use, was sold at 4s. and 5s. per bushel. In the centre arcade, we found the first exposition of imported *Newtown Pippins*, and the *Lady Apple*—both from America. We shall have to remark upon these on a future occasion. *Fearn's Pippin* is abundant; and there are a few *Golden Reinettes*. Some small *Emperor Alexanders* tried to introduce themselves as *Ribston Pippins*; but notwithstanding their very elegant card and gay exterior the hoax was too apparent. Such stratagems won't do; we would rather have the genuine article from the apple-woman's tray, with its "Ribstone Pippings"

on a piece of dirty whity-brown, than patronize such dishonest attempts. In PEARS we have nothing new to notice in addition to what has been stated in former reports. *Beurré Capiaumont* continues plentiful, of fine quality, and some very beautiful, suggesting, by their fine, glowing, clear orange-russet coat, the adoption of one of its other names—*Aurore*. *Duchess d'Angoulême* is fine and tempting. *Marie Louise* good and handsome; and *Beurré Bose* rich and melting. These constitute the principal of the choice varieties; there are, however, several other inferior orchard varieties, which it would be neither pleasant nor profitable to enumerate. There have been some very fine hothouse GRAPES offered during the week, as *Black Hamburgs*, *Muscats*, and *White Frontignacs*, the prices varying from 1s. 6d. to 6s. per pound.

Of VEGETABLES we have nothing to say beyond what we stated last week; prices are the same, and there is nothing new in the supply. POTATOES have had a bad sale during the week, in consequence of an unusually great supply brought by the Great Northern Railway, so that while last week *Regents* made from £7 to £8 per ton, this week they have with difficulty made £5 to £5 10s. This is a common occurrence in our markets; a sudden rise invariably produces a great arrival, and the supply being greater than the demand, salesmen, to save demurrage on vessels, railway trucks, &c., must force a sale, and so the markets fall.

CUT FLOWERS consist of *Camellias*, *Scarlet Geraniums*, *Heliotropes*, *Fuchsias*, *Roses*, *Cinerarias*, *Violets*, *Verbenas*, and *Ceanothus azureus*. By way of giving our friends in the country the *modes* as regards the arrangement of bouquets, we shall, from time to time, furnish descriptions of any which strike us as being particularly chaste or elegant. One, from its simplicity and beauty, attracted our notice during the past week. It was of the usual size, viz., about eight inches in diameter. The centre was a double White Camellia, round which were arranged a double Red Camellia, and a bunch of double Blue Violets alternately, to the number of six in all; the bunches of Violets being of the same size as the double Red Camellia; between the Violets and the Camellias on the outer margin, was a spike of *Mignette*, and the whole fringed round with leaves of the Rose-scented Geranium. Next week we shall give some more illustrations. H.

GOSSIP

THE value of *Orchids* is still well-sustained, for at a sale of an old-established private collection of them on the 22nd of October, by Mr. Stevens, at his auction rooms in King Street, Covent Garden, the following prices were realised:—*Aërides quinquevulnerum*, £14 14s.; *Lelia superbiens*, a fine specimen, £4; *Cœlogyne cristata*, a large and beautiful plant, £5 5s.; *Dendrobium formosum*, healthy and noble plant, with eight flowering bulbs, £11 10s.; *Dendrobium albo-sanguineum*, fine specimen, £7 15s.; *Phalenopsis grandiflora*, a splendid plant, £13 10s.; *Vanda teres*, a very large plant, £7; *Sacco-*

labium guttatum, £6 5s., besides about one-hundred-and-fifty other specimens, which realised prices varying between twenty shillings and five pounds.

On more than one occasion we have impressed upon our readers the importance of using *manure in a liquid state*, but the subject is far from exhausted, and we have been waiting for an opportunity to give a further notice of the highly valuable "Minutes of Information" recently issued by the Board of Health "On the Practical application of Sewer-water." However, as many who read would be well pleased to inspect the results of such application, we call their attention to the following communication:—

"A short time since we inspected some works constructed by Mr. Freeman Roe, hydraulic engineer, of Bridgefield House, Wandsworth, Surrey, for applying liquid manure to his garden and a small field, consisting together of about three acres. The following is a slight description of the works constructed to effect the object in view.—The refuse of the house and stables is conveyed to an iron tank in the stable-yard, situated about thirty yards from the house, and there diluted with water. There is another tank in the loft of the coach-house, to which the water is laid on, and connected therewith is a pump, by means of which the manure in the tank in the yard is pumped up. In the upper tank the manure is diluted to the required strength for distribution. From the last-mentioned tank there is a pipe connecting it with an iron main of an inch-and-a-half diameter, which is laid under the gravel walk running along the entire length of the garden. To this main there are four hydrants attached at different points, and by means of hose the whole or any part of the grounds can be irrigated at pleasure. The hydrants are well worthy of attention, as combining not only very great simplicity of construction, but also another very important feature, that of economy. They entirely supersede the old mode of using posts and sluice-cocks, and there is very great improvement in the mode of attaching the stand-pipe to the hydrant, which is at once simple and effectual. Mr. Roe favoured us with a *fact*, illustrating the superiority of liquid manure over the ordinary process. He has two beds of celery, planted about seven weeks since; to one he has applied liquid manure—the other has been treated in the usual way. A root was drawn from each bed. That treated with liquid manure measured about twenty inches in length, and four inches in circumference; the other root measured only eight inches in length, and an inch-and-a-half in circumference. We have since had another opportunity of inspecting the two beds, and the difference was still more surprising. Such a fact as this speaks for itself.

"We had nearly omitted to mention, that, by a very simple arrangement, Mr. Roe can irrigate his grounds either with water or by liquid manure."

A correspondent writes to inquire whether the celebrated rose-growers, Messrs. Paul, "are relatives of the celebrated *Paul Jones*?" At first we thought that this was an attempt to have a sly thrust at those gentlemen; but as our correspondent referred us to a volume, showing that the celebrated pirate had been a gardener, and was really a Paul, we have procured the volume (*Burke's Anecdotes of the Aristocracy*), and this is the narrative:—

"Paul Jones was born and bred at St. Mary's Isle, the estate of Lord Selkirk, near Kirkeudbright; his father, by name Paul, a steady methodical Scotchman, being head gardener to the Earl, and young Paul acting in a subordinate capacity in the same establishment. In the gardens were two summer-houses, corresponding to each other. One day Lord Selkirk, during his walks, observed a man locked up in one of them, and looking out of the window; in the other summer-house, looking out of the corresponding window, appeared young John Paul. 'Why are those lads

confined?' said Lord Selkirk to the gardener. 'My lord, I caught that rascal stealing your lordship's fruit.' 'But there are two; what has your son done; is he, too, guilty?' 'Oh! no, please your lordship, I only just put him in for *symmetry*.'"

At the *North Staffordshire Agricultural Society's Show*, held at Stoke-upon-Trent, on the 7th of October,

"The poultry stand was a new and highly interesting feature of the exhibition, and towards it all steps were bent immediately on entering the show-yard. Considering the short time within which this part of the show was got up, we may consider it an excellent beginning of a very useful department for the encouragement of one of the most pleasing of rural pursuits. The catalogue contained thirty-two entries (and owing to the short intimation given of the society's intention of having a show in this department, many pens were exhibited whose entries were received too late for insertion in the catalogue), comprising Cochin-China fowls, exhibited by Mr. William Green, of Longton; Captain Blackburne, of Light Oaks; Dr. Gwynne, of Sandbach; Miss Wilson Patten, and Mr. Joseph Bull, jun., of Longton. Those of Mr. Green, in the first class, were valued at as much as £30 the pair. Spanish fowls were exhibited by Captain Blackburne, and Mr. William Mason, of Hardwick; a pair belonging to the former gentleman were valued at £6. Mr. John Stubbs, of Weston Hall, was an exhibitor of several pens of silver-spangled Hamburg fowls; Miss Wilson Patten, of Dorkings; Captain Blackburne, of American turkeys, and half-bred American and French fowls; and George Tallet, Esq., of Oriental fowls—varieties, Cochin-China and Shanghai. The stud of Mr. Tallet, which is exceedingly beautiful, has been entirely raised in the space of fifteen months from Mr. Simpson's (of Sandbach) stock, collected from the best breeds. The Duke of Sutherland sent black Spanish, silver-pencilled Hamburgs, Andalusian, frizzled and silky fowls (the two latter descriptions being both rare and curious), and Rouen and white-crested ducks. B. H. Allen, Esq., exhibited some white Cochin-China, white Dorkings, gray Dorkings, white turkeys, gold and silver-laced bantams, and cross-bred Cochin-China and Dorking fowls; and the Rev. John Sneyd, some fine Norfolk turkeys. There were likewise pens of Chinese golden pheasants, and of gold and silver-laced Poland chickens. Most of these were commended, as they deserved to be, for their beauty, purity, and rarity, and to some of them prizes were awarded.

"The first prize of £1 1s., in Class 1, was awarded to Mr. Wm. Green, of Longton, for a Cochin-China cock and hen, valued at £30 the pair. The second prize of 10s. 6d. to Dr. Gwynne, of Sandbach, for a cock and hen, six months old, valued at £21 the pair. In Class 2, the prize of £1 1s. was awarded to Dr. Gwynne, for a Cochin-China cock hatched in April, and three pullets hatched in March last. The prize of 10s. 6d. was awarded to Captain Blackburne, for a cock hatched in March, and two pullets hatched in April last. A cock and two pullets, belonging to Mr. Wm. Green, were commended. In Class 3, several pens of Silver-spangled Hamburg fowls, the property of Mr. John Stubbs, of Weston Hall, were highly commended; also some Dorking drakes and ducks, belonging to Miss Wilson Patten, some American turkeys, belonging to Captain Blackburne, and the valuable stud of Oriental fowls exhibited by George Tallet, Esq., which comprised the grouse-feathered sub-variety, the black game variety, the Ptarmigan variety, the cinnamon variety, the purple variety, and the partridge-feathered variety, all raised, as already stated, within the last fifteen months, from Mr. Simpson's stock, selected from the best breeds."

The following is a list of the *Horticultural and Poultry Shows* of which we are at present aware. We shall be obliged by any of our readers sending us additions to the list, and giving the address of the Secretaries.

HORTICULTURAL SHOWS.

BURY ST. EDMUNDS, Nov. 26 (Chrysanthemums). (Sec. G. P. Clay, Esq.)

CALEDONIAN (Inverleith Row), Edinburgh, Dec. 2.
 HAMPSHIRE, Nov. 18 (Winchester). (Sec. Rev. F. Wickham, Winchester.)
 LONDON FLORICULTURAL (Exeter Hall, Strand), Nov. 9+, 23, Dec. 14+.
 NORTH LONDON, Nov. 23, Chrysanthemum.
 SOUTH LONDON (ROYAL), Nov. 11+, Dec. 9+, 16.

POULTRY SHOWS.

BIRMINGHAM AND MIDLAND COUNTIES, 14th, 15th, 16th, and 17th December.
 BRISTOL AGRICULTURAL, December 7th, 8th, and 9th. (Sec. James Marmont.)
 CORNWALL (PENZANCE), January 10th, and 11th. (Secs. Rev. W. W. Wingfield, Gulval Vicarage, and E. H. Rodd, Esq.)
 DORCHESTER, Nov. 18th. (Sec., G. J. Andrews, Esq., Dorchester.)
 HONIFON, January 12th. (Sec. H. K. Venn.)
 WINCHESTER, December 1st. (Secs. G. W. Johnson and J. Colson.)

† For seedlings only.

COMBINATION OF FRUIT AND VEGETABLE CULTURE.

THIS may at first sight seem an easy affair, but, judging from the many very bad specimens of gardening in this way we have met with, the reverse would seem to be the fact. A demand seems to exist amongst one portion of the subscribers to this work to possess some sound information concerning it, and, as we must try to attend to all the interests confided to the advice of THE COTTAGE GARDENER, the sooner it is proceeded with the better, on account of the planting season.

One correspondent, who may be fairly taken as a sample, wishes to plant a first-rate Orchard on this system, and says, "I mention the land being my own, to convey to you that I should spare neither pains nor fair expense in having a first-rate Orchard." He says, also, "The soil is a clay marl, (!) eighteen inches deep, on a clay subsoil six inches, and under is marl an endless depth. I have had it drained; pipes are put below the clay into the marl. I have been cultivating it with parsnips, carrots, potatoes, and cabbage, and I mean to continue this." Now this is not only a possible, but a highly eligible course, especially in these times, when recent political changes lead men to consider whether even their garden policies may not be changed, or modified, to meet the times.

Now, although this mode of mixing fruit with vegetable culture has been much decried by some public advisers, yet, with proper management, we think it the very best plan, economically or for convenience. In the first place, many of our readers require the use of both daily, and have not space for a distinct Orchard. They may also desire so to cultivate it as to make it not only serve their family, but turn to some profit in the market by the sale of surplus stuff. Another matter; a garden of this kind is exceedingly interesting the whole year, and this can scarcely be said of the Orchard alone, and it affords healthful exercise continually for those who enjoy a little out-door employ; the pleasure of which is continually enhanced by the sight or thought of Ribston's, of the Maria Louise Pear, or luscious Plums, and the useful Damson, to say nothing of the bush-fruit.

We rejoice to think that such are extending rapidly, and hope to be the medium of suggesting useful ideas, founded on much experience and constant practice, to those about to commence, and who, to excel, should measure their steps carefully. It is needless to discuss soils in the present paper, any farther than to observe, that almost any soil is convertible into this double purpose by skill, labour, and material. Of course, those

which require most, involve the largest outlay, together with reduced chances of that amount of success, without which it cannot prove satisfactory. A good sound loam, slightly adhesive, resting on a dry bottom, is best of all, and should be from a foot to thirty inches deep; the nearer the latter the better for growing good sized trees. Where the soil is only a foot or less, a dwarfing system had better be adopted. Whatever soils are selected, it should be made a *sine qua non* that the subsoil be dry, or rendered so. Peaty soils are probably the worst; but, barring the extra expense of improving, give no cause for despair. Loose sands are the most unfortunate of all; but these might be made to carry damsons, some cherries, and gooseberries. We, lately, saw some good examples of culture of this kind about Hexham, in Northumberland, at least, such they appeared from the windows of our steamer; but the rate at which we were whisked from Carlisle to Newcastle precluded the possibility of making any accurate observation. One of the principal things in this system, is to see that a very liberal width is allowed *between* the rows of trees, at the same time planting them what might be called pretty close *in* the rows. There needs some "breathing room" between the rows, besides cultural space; but it will be observed, no cultural operations but such as have a reference to the roots of the trees, may be permitted between them *in the rows*. Such, at least, should be our practice; and we dare not advise any other.

Another principle must be pointed to: there must be no irregularity in cropping; everything must be in straight lines, and the rows of trees run, if possible, north and south. Any dodging irregularity, any breaking in here and there because the trees in such places have not made equal progress with the rest, will assuredly compromise the chief end and lead to confusion.

Next in importance to good breathing room, is a recognition of a maxim which we long since suggested in these pages, viz., that every fruit tree should, under all circumstances, have a piece of ground peculiarly its own. It is, indeed, the want of a full appreciation of this which has caused three-fourths of the bungling in fruit-culture from time immemorial. Our pot-cultivators of fruits recognise its importance; who ever hears tell of the great Mr. Potvine (not Poittevin) trowelling over the surface of his Hambro's in large pots, and full of swelling fruit, and trying to steal a crop of small salad or lettuce from the surface, not merely at the expense of the quality of the soil given to the vines, but at the cost of valuable fibres; every one of which is wanted constantly on duty; aye, and more too, if procurable? This then, we urge, is the true policy in our present case.

Having planned the *Garden-Orchard*, for we must endeavour to coin a name for this necessary evil, as to size, distance, &c., &c., let beds of soil be thrown up nearly a foot above the ordinary ground-level, in lines where the rows of trees are to be planted: these beds to be four feet wide at first, and continuous, lengthwise. The trees being planted in these lines will, when fixed, have nearly half the depth of their roots above the ground-level, a necessary procedure both for distinctness and in order to keep them as much as possible from descending into the subsoil. This four-foot border will suffice during the first three years, and after this we would make a point of adding one foot on each side every second year. Thus, in the fourth year, it would be six feet; in the sixth, eight feet; and in the eighth year ten feet, which we should consider the final width, unless for very large orchard trees. At the first setting-out there should be an alley of two feet for operations; and this, on making each two year's addition to the border, would have, of course, to recede a foot farther from the trees on each side of the row. On thus removing the alley, occasion may be taken to add extra

nourishment to any delicate tree, by introducing it in the hollow before filling it up.

And now a few words of advice as to the disposal of the borders on which the trees are planted, for we fancy we hear our friend Turn-to-account whisper, that a good deal of surface will be monopolised by these fruit trees: and that he should wish these borders to assist in paying his rental before the trees commence bearing. Certainly; as no produce of any account may be counted on until a third summer after planting, we really must cast about and see if we can serve our friend; but in so doing, we fear being laid open to the charge of inconsistency. It is well known that we have been preaching up *no-culture* for years on fruit borders: "no surrender" has been the word. And, as our good friend Beaton would perhaps say, in a like fix, "the cat will get out of the bag." It so happens, that all the time this doctrine has been broached, we have been slyly stealing a few Dutch turnips from such borders; have even had strawberry edgings, or edgings of curled parsley.

It verily became necessary, after so much digging and cropping over the roots of fruit-trees since the "good old days of Adam and Eve," to try and turn the current another way; and we did, indeed, deem it prudent to take such dangerous weapons as the spade from inexperienced hands; and not only the spade, but the fork, and even hoe for awhile, in order to let the question assume its proper shape. Now that we think and hope that the great bulk of those interested in the garden orchard really begin to appreciate the non-interference policy, we are quite willing to restore them their forks again, and by all means their hoes. Here, one thing must be observed: it is not so much the abstraction of the virtues of the soil that we dread, but the continual shaving away those finer surface fibres which seem disposed to woo the atmosphere, and by which, indeed, the whole system of the tree becomes more sensitive to the invigorating influences of the solar rays. As for the loss in the soil, that can be replaced; and we must some day point to the propriety of top-dressings every three years after the trees have attained a certain age, and well repaid former attentions by abundant crops. Now, there can be no great objection to taking any such crops as can be obtained by from two to three inches' deep culture, although much better avoided. Having practised such things for years, we are in a position to say, that where depth may not be attained by cultural processes, an equivalent must be sought, and that in the shape of manurial matters. With regard to the Dutch turnips, which on account of their moderate tops, and early tendency to bulb, we do hold to be the best things in the main, they may be obtained at easy cost, by merely hoeing the seeds in, killing a crop of weeds at the same time. This we have done scores of times, and the turnips are invariably better for home use than those from deeply dug or enriched soils, which, by throwing them more into top, depreciates their qualities as food for man.

But these are conveniences as matters of profit, not of particular account. Our plan has been to sow Dutch turnips on such borders in the last week of February, or first week of March, in order to get a strong plant before the fruit trees had much foliage, and the only dressing used has been some of the burnt or charred ashes, soil covering, &c., from the rubbish yard. We never sow them nearer than two feet.

Our readers will now naturally desire to know what we think the best distance at which to plant their trees. As to the distance *between the lines* in a *Garden-Orchard*, we say, the wider the better; but, as our small garden men cannot carry out their objects with too high a standard, we think that ten feet of open soil may be the minimum. By open soil is meant the available space for culture when the trees have come into full

bearing; and, be it understood, that although we adhere to strictly-defined lines or boundaries of crops, we place our main reliance on that portion beyond the damaging influence of the branches of the fruit trees. In the rows, we would allow only twelve feet for dwarf standards; tall standards might require nearly double the distance. Before concluding, we may point to the great propriety of those about to establish gardens of this character, of taking into consideration our *platform mode* of planting, full accounts of which will be found in by-gone numbers, the possession of which we consider absolutely necessary to a full appreciation of planting based on root-control and root-culture, the two leading points in a dwarfing system; which dwarfing system, being fairly translated, means early profit, little trouble, and no vegetable suffocation. Allowing each tree, when full grown, to reach nine feet each way, this, with a couple of alleys of two feet each, and ten feet clear cropping ground, would demand, at least, thirty feet from row to row; if forty, all the better.

R. ERRINGTON.

MEETING OF THE HORTICULTURAL SOCIETY—OCTOBER 19, 1852.

THIS was the first gathering of the Society under the new regulations for the exhibition of *special subjects*, in addition to the usual run of garden produce. The special subjects for this day's exhibition were—*Hardy Annuals*, on their own roots, or as cut flowers; *Dessert Peas* now ready for the table; and *Green Peas* in a fit state to "sauce" a Michaelmas goose. There are certain other *specials* named for each monthly meeting, but all sorts of garden produce may be staged on each occasion, as formerly. Foreigners may also compete at these meetings; so that if we are obliged to take the best of their wheats and barleys, we may also get a share of their best cabbages. But we have the better of them this time, so far that they are not allowed to compete against us, only to fight it out amongst themselves; and if a Britisher tries his luck with foreign productions, as a salesman in Covent-Garden Market did on this the first starting day, he will be pitted against a foreigner; and if there is no foreigner to face against him, his things will be judged without reference to home growth. All this is useful, and a great improvement on the old doings of the Society. Of all the *specials* we had an overflowing abundance. Also an overflow of cut Roses, just as they put them up for the summer exhibitions, together with stove and greenhouse plants, and *novelties*, of which (it is but fair) I shall first tell the particulars.

Two splendid examples of the lovely *Vanda cœrulea*, and two or three plants of the finest and most useful hardy evergreen that has been introduced since the Rhododendron was discovered, the coral-fruited *Skimmia japonica*. I would not have lost the sight for a dinner with the Lord Mayor. It seems but the other day that we first heard of such a thing as a blue Vanda; and when we did hear of it, through Mr. Griffiths, who sent over the dried specimens, we did not know exactly where to send for it, only that it grew on a long-wooded range as they go from Sylhet to Assam, the Kaisa or Coosya range; but now Mr. Stevens hammers it away at his auction-room like an ordinary plant. As for the *Skimmia*, although it was named before I was born, there was hardly a botanist in Europe who believed in the existence of such a thing four years since, for there are two marks of doubt against the genus in the last edition of "The Vegetable Kingdom."

The *Vanda cœrulea*, when not in bloom, might pass for some species of the *Aerides*. The flower-stems rise upright first, and then bend gracefully over; the flowers

are not so thick and fleshy as those of the other species, but they are as large, or larger, than those of *Zygopetalum Mackayii*; the sepals and petals are of equal size, and the lip is narrow, and in one of the plants it was of a deeper blue than the other. The flowers are set wide apart on the stalk, and they stand out well from it, on a tube-like pedicel, allowing a free expansion to them on all sides. The colour of the whole is a delicate light blue, something like the colour of the large blue Clematis (*C. cœrulea grandiflora*), or between that and the blue of the *Agapanthus*. Altogether it is a most beautiful thing. There were from ten to twelve full expanded blossoms on each spike, occupying a space of about a foot in length; but when the plant has more time, under good cultivation, we may expect all this to be much increased.

The *Skimmia japonica* was named by Thunberg, and described in his "Flora Japonica," in 1784, when he returned from his travels in the East to occupy the same chair from which he received the first lessons in botany from Linnæus himself. Dr. Siebold missed this plant, as also did Hensall. But Mr. Fortune, always lucky, got hold of it, and the Messrs. Standish and Noble, of Bagshot, have brought it out in first-rate style; as all new plants ought first to be exhibited. It is a dwarf, bushy evergreen, which you might take for a Pontic Rhododendron at a little distance off, but the leaves are thicker, more fleshy, and not leathery, as in this Rhododendron. They are also of a darker green, quite smooth on both sides, and entire round the edges, and without stipules, like all Hollyworts, the order to which it belongs. It flowers in the spring in heads at the extremity of the branches, just like a Rhododendron. The flowers are quite small, individually; whitish, and as sweet as violets. The great beauty of the plant is in its berries. These are now of the same size and colour as those of a bright-berried Hawthorn or Holly, and stand out in prominent clusters exactly as in the common ivy; but Mr. Fortune told me that when the berries are quite ripe, they are as bright and shine like corals. Here, then, is a new plant that will make a scarlet bed all through the winter, to succeed the *Tom Thumbs*, and is equally gay. I believe Thunberg said it grows a yard high, but Mr. Fortune did not see it more than half that height. It is very bushy, however, and all the better for being so dwarf. We have only to imagine a large plot of ground quite covered with three-year-old seedling common Rhododendrons, and these studded all over the surface with Christmas holly berries, and that is just a picture of a bed of *Skimmia japonica*, as nearly as I can paint it. I shall go down to Bagshot some day to learn how they increase it, what kind of soil it likes best, and all about it. There were berries enough on the plant that was exhibited on this occasion to produce some hundreds of plants; for all the berries in this small order yield from two to six seeds each, and the plant seems to flower as early from seeds as the new *Rhododendron ciliatum*, that is, in two years at the farthest.

The next best plant on the table for a gardener, according to my ideas, was one of those dwarf, small-flowering *Chrysanthemums*, called *Pompones*. Some of us gardeners are really very stupid, and more stupid than the rest were those of us who railed against Mr. Fortune for sending home a still more stupid thing, as they called the pretty Chusan Daisy. But a gardener who had seen more than half round the world, and who could send a covey of daring pirates to another kingdom with an old blunderbuss, was not born to be stupid. The first moment he put his eye on this daisy, the image of a new race rose before him, and here am I recommending the very earliest of this race, called *Hendersonii*, because it comes in full three weeks before the old *Chrysanthemums*, just at that period of the whole year when house flowers

are scarcest. It is as pretty as any of them; brownish-yellow, and as double as a bachelor's button. The plant was also the best grown in the room, and I think it was from our own garden, at Chiswick. I hope the judges will bear this in mind next show day, and not be led away by the size of the flowers of *Chrysanthemum*. We in the country, and all who have a grain of common sense, look for the greatest quantity of well-formed flowers which a given plant is capable of sustaining under a system of *close specimen* kind of growth.

You may just as well give sweet cakes to a baby's doll, as give away our money for *cut flowers of the Chrysanthemum*, for that will never raise gardening one inch on the scale of excellence; and if you urge that the ladies like to see them better that way, you must be met by the fact that far better samples of skill and ingenuity may be seen in the shop windows of the milliners.

The most celebrated plant in the room was a cut specimen, in bloom, of the true Peruvian Bark tree (*Cinchona calisaya*). The first, as we were told, that has flowered in Europe. It was from the Society's garden. The flowers are produced, as in *Tacora*, of a pale whitish colour, but the plant is not worth growing for the flowers. *Solandra levis* was there also, from the garden of the Society. A first-rate stove plant that blooms always at this season, and seems much easier to flower than the old *S. grandiflora*, but the flowers of both are much alike, large, white, and somewhat bell-shaped. No plants are more easy to grow and propagate, but the difficulty is to flower them well; and the way to do that is to give them a long season of rest in a perfectly dry hot atmosphere, without a drop of water till the young wood begins to shrivel. This *levis* is rather new, having only flowered for the first time in England in 1847, at Mr. Pince's nursery at Exeter. There was a nice-looking *Gesnera* from Mr. Glendinning, which looked as if it were a cross between *purpurea* and *discolor*. A fine dwarf plant of *Medinilla Sieboldii* was there in fruit and flower. The flowers are pale pink, in bunches; and I believe they said the berries were to be of a high colour when ripe; it seemed the best of them for a small house, as this plant was quite bushy, and not higher than a fancy geranium. A fine tall plant of *Dichorisandra* coming into flower,—a very useful thing at this season, and easy enough to grow and flower in a stove, and then to stand in a flower-house for full two months in fine blue bloom. This is, also, one of those free-and-easy plants from the stove that will grow out-of-doors from the end of June, and look better than in the orchid-house. I had it so growing many years since. But speaking of house plants for out-door culture reminds me that we had here a new rival for the variegated and blotched-leaved section, which I wish so much to see tried in the open air in July, August, and September. It was from Mr. Low, of Clapton, where I saw lots of it when I went to learn about the packing for long voyages, and where I booked it, and a great many other things, for these pages. The name is *Plectranthus concolor-picta*, a plant looking somewhat like a *Salvia splendens*, but with leaves much paler, and of more varied outline; and in the centre of each leaf there is a large blotch of purple-brown, as if a painter had touched it with his brush accidentally. It is, certainly, unique, and well worth adding to every collection of variegated plants in the kingdom. The less that is said about the flowers of any *Plectranthus* the better.

There was a fine specimen, in the shape of a cut top, of the *Aralia japonica* in flower, from Mr. Snow, gardener to Earl de Grey. It was the finest of the kind I ever saw, and it was but one panicle out of a great many now adorning this very fine shrub, and as it is very seldom seen, I must give some idea of it, as I always attempt to do when I write about any new or uncommon

plant. The flowers are small, white, but very numerous produced along the side spikes of a large loose panicle, coming out at the end of the branches, exactly as they do in *Kœlreuteria paniculata*, another beautiful hardy tree that is not planted half so much as it deserves to be. As Mr. Fish lives not far from Mr. Snow, perhaps he could fish out how this beautiful *Aralia* was treated to get it out so fine; and, indeed, any of our correspondents who may happen to have old established plants of it, would confer a benefit by a sketch of the proper culture. A little Begonia-looking plant, with racemes of small, bright lilac flowers, called *Puya zelanica*, was curious and well worth growing in a small collection of stove plants, as it requires but very little room. *Guzmania tricolor*, an old member of the Bromeliads, looking like a stunted pine-apple plant, had a spike of bloom up from the centre, just in the shape of a pine-apple when it first shows. I never saw this plant in flower before, and it is certainly very pretty and very curious, after this fashion—on the top, where the crown of the pine-apple shows, there is a close bunch of leafy bracts, in crimson-scarlet; below that, and where the pips of a pine-apple would stand, the buds of the flowers were peeping out from between the bracts, just like the tops of so many white crocuses in bud, and the colour of the bracts round their white buds, so to speak, was green, or brown, or streaked, altogether forming the *tricolor* to perfection. None of these Bromeliads are difficult to grow, and they come from suckers as freely as the pine-apple, and they often seed. I am quite sure that most of the store ones would grow and flower beautifully without a particle of soil, like air plants, only having their scanty roots placed in balls of moss, and wound round with small copper wire; then to hang them up against walls, posts, or pillars, and to keep the hollow of the leaves always quite brim full of water, and also to dip the mossy balls continually in water, as Mr. Jackson, of Kingston, does with the lovely *Vriesia speciosa*, alias *Tilandsia splendens*, of which I saw a large stock of seedlings with Mr. Low, at Clapton, the prettiest little things you ever saw, except a drove of speckled fawns or kids. There were two more plants of this order in the way of *Pitcairnea*, one of them very handsome, and the other no-matter-what. The right one put up a flower-stem from the middle, in the usual way, and on the top was a fine crimson head of flowers; the second plant grew in the same way, but the flower-head was a greenish-white. Take a crimson *Love-lies-bleeding* or *Coxcomb* in one hand, and their white varieties in the other, and you have the contrast of these Pitcairns, or whatever they may be, to the very letter. An African traveller showed me a little yellow *Lachenalia*, at one of the Regent Park Exhibitions this last summer, and a dried specimen of a Yellow Geranium one day at Chiswick. I thought the man was daft for his pains. I think otherwise now, after seeing this very pretty species of *Lachenalia* at this meeting. I think it was from the garden of the Society; at any rate, it was capitally grown, and when the bulbs are stronger this will become as a general favourite as *Lachenalia tricolor*, and is well worth having. With the exception of these two species, all the *Lachenalias*, and some of them are very pretty, ought to be set in pure silver-sand, and put in very shallow in the pot, with about half-an-inch of sandy peat on the top, and rough turfy peat, with good drainage, below, and no water ever allowed to get in between the leaves, these bulbs being so touchy that the slightest mishap will rot them. There was a large specimen of *Plumbago Lar-pentæ*, which was in fine bloom when I was at Chiswick in September, but now was too late for it. Also a fine plant of *Sedum Sieboldii*, a plant that is admirably suited for a small neutral bed in an architectural or terrace garden, the effect being more from the sea-green of the leaves, than from the purple blossoms in the autumn.

There was a little plant of *Campanula Vidallii*, which did not show the full character of the species. I heard it run down in one or two places in Oxfordshire because it would not stand the rain; but I have not seen it anywhere so that I could pass a decided opinion of it as a bedding-plant, for which it was first given out.

There was a very pretty, pure white, new, *Trichophyllum* from Mr. Bellenden Kerr; also a botanical *Dendrobium* from some one; another botanical, or, rather, a Manchester plant in fruit, "The Sea Island Cotton Plant;" with *Abelia rupestris*, and twenty-seven kinds of annuals, altogether making a good October meeting without yet coming to the *specials*, of which these annuals are a part. *Cosmos bipinnata* and *Coreopsis filifolia* are the only two out of the lot that are less known to the readers of this work. The *Cosmos* is an excellent wilderness plant, looking as if flowers of the Beauty of Thetford Dahlia—the best of all the single ones—were placed on some loose-growing, fennel-like plant, rising from three to four feet. The *filifolia* *Coreopsis* is so much like the *Drummondii* in flower, that it is not worth a place for its thready leaves. *Lupinus rivularis* is also not so much known as it ought. It is a much deeper blue than *Hartwegii*, and it is less dense in the growth and leaves; but in every other respect, as to height, time of flowering, and treatment, it is the same as *Hartwegii*.

A large bed of the best annual Lupins ought to stand thus—*Mutabilis*, four feet high, in the centre of the bed; a row of *Lupinus Hartwegii*, as being the next in light blue shade; the third row to be of *rivularis*, a darker blue; the fourth, also a row of *rivularis*, to be cut in to eighteen inches high, and not to allow it to rise higher all the season; and the outside row to be of *Lupinus nanus*. Then there would be a regular face of leaves from the ground level, and the best shading that can be made out of *Lupinus*. The whole would keep in flower till October; and the reason why I mention it, is to show that without the second row of *rivularis*, and that kept to a certain height, to suit the rows on each side of it, the arrangement would be a failure, because there would be too great a step between the flowers of *nanus* on the outside, and those of *rivularis*. This great blemish is often coming in now in plans of flower-gardens, and nothing looks worse.

There was a large pan of the gem of *carpet plants*; also an annual, *Cochlearia acaulis*, only two inches high, and all flower, and so easy to grow, that it only requires once to get a footing to keep itself from year to year, especially in a peat bed. The lecturer was very earnest in pressing and explaining all this, and he gave a new turn to the subject this time, which set my teeth on edge. This *Cochlearia*, with its pretty white and blue flowers, may be had on the mantel-piece, or anywhere else in a room, everyday in the year; and not only that, but it will do as well in the saucer of a tea-cup as in the best pot. The way to do it is this—to keep sowing it at different times, and to let it sow itself, so as to have some always in the borders. Then to take your saucer, or little vase, to the border, fill it nearly with soil, and take up patches of this plant in bloom, press them on the top of the mould in your vessel, and next day they are in full bloom. They will last three weeks; then fill again, and so the whole season. If they get behind in flowering out-of-doors, take them up all the same, and the heat of a room will soon cause them to flower. All this was new to me; and I shall never take the spoon out of another man's mouth if I can help it.

Green Peas in pod, and table *Pears*, with *Grapes* and *Pine-apples*, were in abundance, and some were remarkably good.* There was one bunch of a black

* The *Peas* to which were awarded the prize, were *Knights Marrows*, young and excellent, from Mr. Burns, of Chevening. Others, as the

grape, which I would call a monster Black Prince; the weight was 3 lbs. 9 ozs., but the owner, Mr. Butcher, a nurseryman at Stratford-on-Avon, told me that this grape would keep till late in the spring. The name of the grape is *Black Barbarossa*. It had a medal, and it richly deserved one, still, as this is a very little known kind, if the Society did not request to see a bunch or two of it in January and February, or as late as it could be kept fit for the table, they might just as well have thrown this medal over London-bridge. Scotland excelled in table Pears, and it was provoking to hear the lecturer following up this triumph, by raking up the horrors of the winter of 1837-38, when many tender plants stood out "over the borders," that were killed outright about London; and yet I often had a mind to tell Mr. Errington, that if he ever wanted to see pear and peach-trees in perfection, he would need to go into Fife, Perth, or Morayshire, for the sight. The island of Jersey never sent out finer pears than a pear at this meeting, called *Grosse Calabasse*, from Mr. Robertson, gardener to Sir A. Dumber, Bart., Dufus House, near Elgin, a day's journey beyond Balmoral, when I was last there. "The Heart of Midlothian" was also represented by splendid Pears from Exenford Castle, two hundred miles nearer Gretna Green than Elgin. After the Elgin Pears, the next largest were *Duchesse d'Angouleme*. We had also Apples, Plums, Morello Cherries, and Guavas.*

D. BEATON.

GREENHOUSE PLANTS SUITABLE FOR POT-CULTURE ON TRELLISES, &c.

PLANTS fitted for this purpose should possess a climbing, twining, or trailing habit. Where conveniences exist, the last division would look most natural if the pot or basket was suspended, and the shoots allowed to fall gracefully over the sides. Many of the others look admirably when twisting round an arch, or dangling from a rafter. But some are rather slow growing for this purpose; and where a great love for such forms of beauty exists, only a small number could thus be grown. When cultivated in pots, on trellises, a greater variety can be obtained, more dense masses of bloom secured, and the plants can be easily moved from place to place, and thus obtain the best position, as the varying circumstances of the plants require. Of the many that might be selected, I shall to-day allude to the *Kennedy* group, merely premising that all the strongest growing are also fitted for rafters, when planted out and grown in larger pots than would be requisite for trellises. The strongest growing will, therefore, be named first.

The genus *Kennedy*, consisting of pea-shaped flowers, is commemorative of Mr. Kennedy, of the late firm of Lee and Kennedy. The plants are all natives of New Holland, Australia, and the Swan River settlement. Much confusion exists in this group since botanists have divided it into other two allied genera—*Hardenbergia*, commemorative of a sister of Baron Hugel, and *Zichya*, in honour of another German lady, a friend or relative of the same gentleman. Was this the proper place, I do not think I could in every case draw a clear distinction between the three genera, as even in the most recent lists they seem very much commingled together, so much so, that beginners could not greatly err in calling the whole lot of them *Kennedias*, at least, until one of our botanical friends will point out a clearly perceptible difference. In most cases, though not in

all, the *Kennedy* has trifoliate leaves, and the keel of the flowers longer than the wings; in *Zichya*, the keel is short, the leaves trifoliate; in *Hardenbergia*, the leaves are mostly simple and long. As a slight difference will be required in the management, I shall give a short list under the several genera.

Kennedy *nigricans*.—Flowers very deep purple, green, and yellow. This, a number of years ago, we had so strong as to threaten to monopolise the whole roof of a house, and when dangling down the flowers had a very singular appearance in the spring months. Many of the *Kennedias* are climbers, but this is such a twiner that it grasped an iron rod so tightly as ultimately to destroy itself.

K. Marryatta.—Fine scarlet flowers; blooms freely from February to June.

K. rubicunda.—Dark dull red; blooming generally from May to July. These, when grown in pots, will require trellises from four to seven feet in height, and eighteen inches in diameter. If in a balloon shape, the widest part may be a foot wider. The smallest trellis for the last-named.

K. Comptoniana.—Blue-lilac.

Hardenbergia macrophylla (Large-leaved).—Scarlet flowers.

H. monophylla (One-leaved).—Blush-purple.

H. longiracemosa (Long-clustered).—Purple-pinkish.

H. ovata (Egg-shaped-leaved).—Purple.

Many of these, if left to themselves, would have as much tendency to trail as to climb. The trellises should range from six feet to three.

Zichya glabrata (Smooth-leaved).—Orange flowers.

Z. sericea (Silky-leaved).—Scarlet; syn. *Kendilata*.

Z. inophylla (Nerved-leaved).—Scarlet flowers.

Z. heterophylla (Various-leaved).—Purple.

Z. tricolor.—Yellow, red, and purple.

These are pretty twining plants, requiring trellises from 3½ to 2 feet in height, and from 30 inches to 18 inches in diameter.

1st. *Propagation*.—When seed can be obtained, sow in February or March, in sandy peat, plunged in a sweet hotbed: steeping the seeds previously for a day in water at 90°; hardening-off the plants gradually, as they get strong enough for pricking-out round the sides of a pot. *By Cuttings*, choose firm, short, side-shoots from two to three inches long, early in spring, or after fresh growth in summer, when the base of the short shoot is getting hard; and insert them in silver sand, over sandy peat, the pot being three-parts filled with drainage, and kept close with a bell-glass; shade when necessary. Give a temperature rather higher than the plant enjoyed from whence the cuttings were taken; and in a month or six weeks plunge the pots, if necessary, in a slight bottom-heat.

2ndly. *Choosing young plants in a Nursery*.—Fix upon the healthiest and bushiest at bottom. But, provided the plants are young and vigorous, though they be rather naked below, it will be of less consequence than if you were purchasing bush plants, to which a good bottoming is everything. This will appear from

3rdly. *The mode of Training*.—When I used to grow such plants I practised two modes. First, I encouraged the plant to grow with a single stem until it was a little higher than the top of the contemplated trellis; then it was stopped, and all side-shoots and buds on the stem were disbudded gradually, after the shortened top was beginning to push out fresh branches. These were allowed to dangle free of each other, or were secured to any temporary prop, so as to have a good beginning before the trellis was introduced. The main stem, by this means, became as clean as a whip-handle, and, in fact, was never seen at all when once the trellis was covered; besides, the sap was distributed more regularly than when the trellis was covered with rival

Long Jonquil, but little known, from Mr. Evershed, market-gardener, of Godalming, and *Early Warwick*, grown by Mr. Smith, gardener to Mrs. Reay, Wansted, were so good as to deserve an extra prize. Some foreign Peas were also exhibited, but these were in very bad condition.

* The pears exhibited by Mr. Robertson, were Winter Neelis, Sinclair, Marie Louise, Easter Beuré, Grosse Calabasse, Thompson's, Duchesse d'Angouleme, and Glout Morceau.

branches from the base. This method I found a good one for causing free-flowering among the stronger-growing *Kennedias* and *Hardenbergias*, from the check given by training the branches downwards. But, again, suppose you have got a plant of the slower-growing *Zichyas*, that you wisely resolve to cover a trellis with, beginning at its base, and you have either got a solitary shoot, or several shoots, bare for a foot or eighteen inches from the surface of the pot; then the best thing you can do is to give the plant the usual good treatment, until the month of April, or the beginning of May. Then prune it back, not to the surface of the pot, but so as, if possible, to retain a few leaves to keep up the circulation; then tie the shoot, or shoots, to the side of the pot, in order to cause it to break more easily. Place the plant in an increase of temperature of ten degrees, and in a moist atmosphere; and if the stem was not very hard and old, you will get plenty of young shoots to choose from. When these are from one to two inches in length, a fresh shift may be given, if the roots require it, and a vigour will be secured that the old stunted stem never would have yielded. Mind, if the stem is *old*, pruning back close to the pot will be likely to end in death. If the stem was quite young, it might be cut back close without danger.

4thly. *Potting*—when should it be done? When the plants are young, and small shifts are given, attend to them as often as necessary. When they become large, once a year will be ample, and that is best done when the plants are commencing to grow freely after flowering, and receiving what slight pruning they require. Established plants on trellises will not want potting for several years, if the surface is freshened up, and weak waterings from old cow-dung given when blooming and growing.

5thly. *Size of pots*.—Eight inches in diameter will grow the smaller *Zichyas*, and those from twelve to sixteen inches will do for the stronger of the allied genera.

6thly. *Trellises*.—These are most convenient if made of wire, and coloured a dark brown or olive-green. Young Larch-trees, peeled so as to have all the twigs left, then thoroughly dried, and either painted or not, do very well, but require to be fixed in the pot—a great disadvantage—and also demand more labour in training. Two things are necessary to be attended to with wire trellises: First, that they should be fixed to the pot, instead of going into the soil; secondly, that they should be round in form, instead of square or semicircular; and, I may add, thirdly, that the training, when the plant is established, ought to hide the trellis, and the twigs hung in massive, careless profusion, instead of each being stuck in its place with mechanical precision. Never forget that the trellis, however pretty, is merely a necessary supporting crutch, and that plants, as well as men, look none the worst when they *seem* independent of such aids.

7thly. *Soil*.—Heath soil must constitute the chief material for all when young, mixed with a little charcoal and broken potsherds, both of the latter being clean and free from dust. As the plants increase in size, a little at first, and then more loam may be added, of a very fibry character, until, for *Kennedias* and *Hardenbergias*, it may constitute one-quarter, peat one-half, and charcoal, broken pots, and sand, another quarter. When the trellis shift is given, the compost should be pre-eminently fibry and rough; but few of the individual pieces should be larger than a walnut, and most of the small earthy matter be excluded, using enough of silver sand, &c., to keep all in an open state when firmly pressed. It would be advisable to use small successive shifts, until the plants filled five-inch pots or more, and then transfer them, by a large shift, to the trellis pot.

8thly. *Watering*.—The roots must never be allowed to become dry, but comparatively little will be wanted

in winter, or in dull weather. If well drained, and the soil open, as advised, they are not easily injured with water, provided its temperature is sufficiently high, and there is no want of light. Plants that have received a large shift must be watered very carefully for the first twelve-months, more especially in winter, as if the unappropriated-by-roots soil, close to the sides of the pots, were soaked and soured, the plant would be greatly injured. A little manure-water may be safely given when the plant is growing after flowering.

9thly. *Pruning*.—This will be required according to the strength of growth, performing the operation after flowering. Prune so as to secure healthy, well-ripened shoots for the next year. In some cases the bloom is chiefly produced near the points of such shoots, but mostly either in single blossoms, or racemes from the axils of the leaves.

10thly. *Time of Flowering*.—This, with the kinds mentioned, may be expected to last from March to the middle of July; earlier or later, according as the plants have been accelerated or retarded, by being kept in a warm or cool greenhouse during the autumn and winter.

11thly. *Temperature*.—They may be kept at from 40° to 48° in winter, but if often below 40°, or in dull cold weather kept long as low, the plants will feel it, and more especially if the soil is wet. I have had fine specimens rendered worthless from cold alone. The leaves, especially of the simple-leaved kinds, seemed as if they had been burned, but the cold it was that scorched them. Were I growing plants as specimens again, my previous experience would point to 45° as the lowest average temperature at night, but I should not like to see them long under 48°, and in fine weather, a couple of degrees higher, with an allowance of 10° more for sunshine. They who study the native climate of these plants, will see the necessity for this. The other seasons may be mostly regulated by *position*. Expose the plants close to the glass in spring; keep them slightly shaded and cool when in bloom; more shaded, closer, and in a moister atmosphere after pruning; freely exposed to the sun in the end of summer; and during the autumn, never putting them out-of-doors at all, unless in warm autumns, in a sheltered place, full in the sun, the pots protected from its rays, the plants housed before cold nights come, and obtaining a *light*, open position all winter. If on circular trellises, they should be turned partly round every other day, that all parts may have light alike.

12thly. *Insects*.—Red Spider sometimes comes—but that, sulphur water, or sulphur fumes, will cause to flit. A worse enemy is a white scale insect. At first, and when thin, washing off with soap water may aid you; but when once colonies are formed, a young plant, or cutting down the old one and commencing anew, are your best remedies; in the latter case scrubbing well the old stems as the preliminary process. Against these annoyances, *cleanliness* and high health are the best safeguards, and for this purpose the syringe and tepid clear water are good agents, applied sparingly in sunny days in winter, and morning and evening in summer and early autumn.

R. FISH.

THE PETUNIA.

THIS is a florist's flower that is advancing in public estimation, both as an ornament to the greenhouse-stage, and to the flower-garden as a bedding-out-plant. Perhaps the best that was ever yet raised is the one known as the *Shrubland Rose Petunia*. It is equally beautiful in the greenhouse, and in beds in the open air, yet I suspect there are several varieties something like it sold for it, and I draw this inference from the fact, that a gentleman from Manchester writes to me for the

true one. He says he has had several that have turned out counterfeits, which, like counterfeit sovereigns, are useless, except to the utterers, when they are not caught in the fact. There is nothing so grievous to the mind of a respectable dealer as that of sending to his customer a plant not true to its name, which he has had from some person in the trade, expecting it to be the genuine variety. If he is largely dealing in any popular plant, and has obtained the origin of his stock from some one that has deceived him, I leave a discerning public to judge how distressing his feelings must be, when he finds he unintentionally has been distributing, to perhaps numerous customers, a plant not true to its name; and what is worse, spreading the mistake, or evil, it may be designated, on account of his high and deserved (except in such a case) character, he has been supplying other men in the trade, equally as respectable as himself, with plants from the false one. This is a great evil, and I think the sending out plants, in the first instance, of any kind not true, ought to be punishable by an expressed law, for there is no knowing how far, through the innocent instrumentality of the honest well-known sterling dealers, the deceit may be spread. These remarks have been drawn from me in consequence of the letter from my Manchester correspondent, and I trust if ever a dealer is found wilfully and knowingly sending out to nurserymen any kind of florist-flower not genuine, that, for the protection of innocent men, and the public in general, such a dealer may be publicly exposed in the gardening periodicals, such exposure to operate not only as a warning to would-be-cheats, but also as a punishment to the actual offender in the first onset.

I have been drawn from my original purpose when commencing this essay on the *Petunia*, and if I have made myself clearly understood, I may hope my remarks may do good, by removing the onus of wrong dealing from the innocent, and placing it where it ought to be, upon the guilty man. The *Petunia* is advancing, not only in public favour, but also with the florist, because it is found capable of improvement by hybridization. I may suppose now that the *Petunia phanicea* is extinct; but I well remember, some twenty years ago, being highly delighted when I first saw the plant in flower. It had then a great degree of beauty, but was without a good form. My young brethren would scarcely recognise it now, in these days of improvement, in form, colour, and substance—the three grand properties of every florist-flower. As I do not desire to omit any flower that can be placed under the class of florist-flowers, I shall devote a week's essay or two to this showy plant—the *Petunia*, and after they are placed in the hands of our Editor, I will give a series of brief descriptive lists of every kind of florist-flower that is worthy of cultivation in 1853, something similar to the one I gave lately of the *Dahlia*. I am aware that this is an onerous task, but I do not shrink from it, being well aware such lists are extremely useful and desirable to the amateur florist, for whose instruction I chiefly write on this subject; and I should be much obliged to every grower of good varieties of any kind of these flowers, if he would send me a true description of every first-rate variety, in order that the list might be complete, and, consequently, more extensive and useful; the descriptions to be classed under the heads—form, substance, colour, size, and habit. Such lists, drawn from various quarters, would be far more complete and essentially useful than any single one that any one dealer might furnish in his catalogue. I hope my wish for these descriptions will be attended to at once, as the season is fast approaching when it will be desirable to put them into the hands of the purchasers, in order that they may procure them in time for the next year. They may either be sent to me, at Victoria Nursery, Uxbridge, at once, or be sent to the Editor, 2, Amen Corner, Paternoster Row, London.

To return to the *Petunia*. In the first place it is desirable to know what are the properties of a good *Petunia*. 1. *Form*.—The flower should be round without notches on the edge, and it should be rather inclined to cup, that is, the outer edges should not bend back. 2. *Substance*.—The petals should be stout, and able to keep the form nearly as long as the colour lasts perfect. 3. *Colour*.—When a self, it should be clear without fading at the edges; when striped, each stripe should be well defined, and each colour distinct. 4. *Size*.—Each flower should be at least one-and-a-half to two inches across; if large they are liable to bend back. 5. *Habit*.—The plant should be rather dwarf, and produce flowers abundantly; the foliage should be rather small, in order that every flower may be seen distinctly. T. APPLEBY.

(To be continued.)

CONIFERÆ.

(Continued from page 46.)

DACRYDIUM.—This name is derived from *dacru*, a tear, on account of the gummy tear-like exudations on the leaves and branches. The foliage of the plants in this genus are singular and ornamental. I had intended, when I first began these essays on *Coniferæ*, to confine myself to the hardy species only; but as *THE COTTAGE GARDENER AND GENTLEMAN'S COMPANION* is now found on the tables of those who have large conservatories, I think my list ought to include such *Coniferæ* as are ornamental and suitable for such garden buildings. For this reason I include the genus at the head of this article, and shall also include other genera of a similar character; and I do this for the simple, yet sufficient, reason, that of rendering the essays complete and useful to every class of readers. That the genus *Dacrydium* is too tender to bear the open air is, I fear, too certain a fact; but the species are admirably adapted to ornament a conservatory or winter garden, either planted out in the borders, or grown in pots. In either case, they should be grown in pure, strong loam, well drained.

DACRYDIUM CUPRESSINUM (Cypress-like D.), from New Zealand, where it is called by Europeans the New Zealand Spruce Fir. Dr. Solander first discovered this tree when accompanying Captain Cook on his first voyage. That attentive commander, in order to prevent the attacks of that scourge of sailors, the scurvy, made from this tree a kind of spruce-beer, but found it so very astringent, that he was obliged, in order to prevent the bad effects of this quality, to mix it with a tea made of the tea-plant of that country (the *Leptospermum scoparium*). This species was found on the sides of the hills, and also on the sea-coast nearly down to the water. The trees were tall and slender, reaching nearly one hundred feet in height, whilst the stems seldom exceeded three feet in diameter. This disproportion, however, was not seen, because the stems were hid by wide-spreading, drooping branches. The wood is hard, more so than any other resin-bearing trees in that country, and is beautifully variegated with white and red.

DACRYDIUM ELATUM (Tall D.).—This is the *Juniperus rigida* of Dr. Wallich, and the *J. elata* of Roxburgh. It is a native of Pulo-Penang. The tree attains a great height, and is very ornamental. Introduced about 1830, but is yet rather scarce.

DACRYDIUM FRANKLANDII *syn.* *D. HUONENSE* (Huon Pine), found in a district of that name in Tasmania. This is a valuable tree in that country; the timber is used for ship-building and other purposes. Mr. James Backhouse, the nurseryman at York, travelled through that part of the world, and wrote a very interesting "Narrative of a Visit to the Australian Colonies," and describes this tree to be large, and of a pyramidal form, growing to the height of a hundred feet, with a trunk

twenty-five feet in circumference. The branches from the trunk are nearly horizontal, and are clothed with numerous, slender, pendant, scaly branchlets, of a lively green, serving the purpose of leaves, as is the case with the Cypress and Arbor Vitæ. The wood is close-grained and more durable than the White American Pine, and has an aromatic smell. There are some specimens of this very handsome Pine in the greenhouse at Kew that have attained the height of five feet in pots. If they were planted out in a large, lofty conservatory, they would rival in beauty the beautiful *Araucaria excelsa*. The plant strikes easily from cuttings, and is now to be found in most of the nurseries near London.

DACRYDIUM MAI (Mai D.), so named by Mr. Cunningham, who discovered it in New Zealand. Very little is known about this species, though it is, I believe, in Messrs. Knight and Perry's unique collection of these interesting plants.

DAMMARA.—The Dammer, or Amboyna Pine, a very remarkable genus, but, like the preceding one, not quite hardy in this country. The genus differs from other Coniferæ in its leaves, which are broad and long, like a more common deciduous tree. The name, Dammara, is derived from the Malay language, the word being applied by the natives to the resin the plant (*D. orientalis*) produces. This resin is very curious; it is transparent as crystal, and hangs from the trees like icicles, a foot long, and three or four inches broad. It is much prized by the natives, and used as incense. The trees attain the height of eighty feet.

DAMMARA ORIENTALIS (Eastern Dammer Pine, or Amboyna Pitch-Tree).

DAMMARA AUSTRALIS (Southern Dammer, or Courie Pine).—This is a tree that strikes Europeans with surprise in its native woods, where it grows seventy feet without a branch. This peculiarity renders the timber valuable from the absence of knots; and added to that is the fact, that the timber is excellent. It produces, also, resin as abundantly as the eastern species, and is, besides, much hardier. In the warmer parts of Europe, this tree, on account of its valuable properties, should be planted largely; but in this country we must be content to admire its beauty in our lofty conservatories.

FRENELA (Meaning unknown).—This genus was established by Mirbel, and is used by Messrs. Knight and Perry in their excellent Synopsis of Coniferous Plants, to which I am largely indebted for many facts on this interesting tribe of trees.

FRENELA AUSTRALIS, *Cupressus Australis* in *The Cottage Gardeners' Dictionary* (The Southern, or Oyster Bay Pine).—This tree is found on the eastern coast of Tasmania, better known as Van Diemen's Land. Mr. Backhouse says, that though the tree is small, seldom exceeding fifty feet high, yet it is useful for building purposes, and has an aromatic smell. It is the *Thuja Australis* of Desfontaines.

FRENELA CUPRESSIFORMIS (Cypress-like F.).—New Holland.

FRENELA FOTHERGILLII (Fothergill's F.).—Native of New Holland.

FRENELA MACROSTACHYA (Long-spiked F.).—New Holland.

FRENELA TRIQUETRA (Three-sided F.).—New Holland.

All these are greenhouse or conservatory plants, though some of them have lived for some years in the south of England and north of Ireland without protection. They are singular, curious trees, having much the appearance of the common Equisetum or Mare's-tail of our swamps, magnified into trees. They are all easily grown in sandy-peat and loam, and propagated by cuttings.

T. APPLEBY.

(To be continued.)

ON THE FORMATION OF SUBURBAN GARDENS.

It very often happens that a space of more or less extent is found at the sides or back of many of our villa, or suburban houses, which the taste of the owner would be glad to see converted into something useful. I do not here mean those "front gardens," about the laying-out of which so much difference of opinion is abroad, but those slips or yards at the less exposed sides of the house; and which, though often hemmed in with buildings, are yet free from that incessant traffic which marks the "kitchen or stable yard:" in fact, I mean those snug out-of-the-way corners, where the ordinary business of the household brings but few trespassers. Many of these little spots are highly cultivated, and afford the occupant many a pleasant hour, when the stern business of city concerns are over for the day; while, on the other hand, we have been pained to see the evil effects of attempting too much on such little spots. It is in vain to think of making a park out of a pocket-handkerchief; and it is equally vain to think of growing many of the more cumbrous vegetables on a spot not much larger than a dining-room carpet. In vain does the anxious proprietor (in the afternoons when he returns from the scene of his city labours) look for the smaller vegetables and other crops, progressing under a heavy load of scarlet runners, or "Somebody's" tall marrow peas, which he was induced to buy and plant upon the authority of their raiser's advertising claims. I say, in vain he may look for any thing in the shape of onions (except an elongated stem like bullrushes), where the better half of his bed is overwhelmed by the pondrous mass of scarlet runners, which his sticks have ineffectually struggled to maintain in an upright position. A similar disaster will most likely befall any small produce that may have a tall growing potato for a neighbour; and, in fact, the anxiety to obtain so much from so limited a spot leads to disappointment quite as great as that of attempting to give the few rods of ground in the "front garden" a "park-like appearance." Objects of art may be exhibited in miniature, but those of Nature can rarely be made so to conform with anything like a satisfactory result; therefore, the inexperienced suburban occupant, who has such a small plot to occupy with some of the useful productions of cultural science, must remember that the very excellent things he is accustomed to look upon in Covent Garden, and other markets, are the produce of many districts, wide apart, but which the experience of many years has proved to be the best for producing each of them in that perfection he sees so good. Though he cannot reasonably expect to equal them, yet he may grow many things to a tolerable degree of excellence, provided his soil, situation, and other things be all favourable.

Now it often happens that ground in the immediate contact with buildings has received an accession to its ordinary condition, in the shape of large quantities of earth and other materials dug out of the foundations, &c., of the surrounding structures; yet it rarely happens that those who have the care of depositing such matters have any regard at all for any future use the ground may be put to; unless, perchance, they think it a suitable place on which to pile up some more of their bricks and mortar; therefore, it is not unlikely but the amateur, when he first puts his spade in the "back yard," finds its downward progress arrested by some stone too ugly to work even into the foundation; or, it may be, the spade may be drawn up with a material clinging to it which he in vain tries to disentangle, so often does the stiff adhesive clay of the subsoil get brought to the top when there is no ultimate object in preventing its being spread there; should the latter be the case,

the amateur must, as carefully as he can, remove a great part of it, and after getting at the good soil, which for distinction I will call "natural," he must endeavour to bring that to the surface, burying a deal of the waste matter at least two feet below the surface, providing he cannot afford to take it away altogether. In this operation, be it remembered, that all opening or porous substance might with advantage be retained, and these being mixed with the clay, will produce an effect tending to its amelioration. This class of fertilizers includes all the waste mortar that can be had, chippings of stones, and bricks; and even wooden chips are not without their uses. Supposing the clay to be buried beyond the ordinary reach of cultivation, yet it is better that the subsoil should be to a certain extent porous, and the articles above-mentioned are the best of any for making it so. I have said nothing of draining, because I apprehend that the welfare of adjoining buildings had rendered that important object necessary before gardening was thought of; if not, some little difficulties may exist in the way of disposing of the water; but this can only be arrived at on the spot.

This preliminary operation being performed, it is better to wait awhile before advancing much further, if circumstances will allow of delay. Ground that has been trodden upon, and covered up beneath a mass of impenetrable matter, requires exposure to the atmosphere before it regains those fertilizing properties it held previous to its interment; and at whatever time of year the operation of raising it to the surface is performed, a more or less period of preparation is required before it be fit to support vegetation, or to afford it those nutritious juices so necessary to its support. This process is more slow in autumn than at any other period of the year; and, perhaps, it may be more active in the hottest part of the summer. The cold drying winds of spring are not without their uses, neither are the winter frosts; the last, perhaps, being the best for extracting all pernicious matter, and loosening those bands of adhesion, a loosening so essential to soils becoming fertile. Now the same rule holds good here, which we have so often laid down for the trenching or tilling of ground—it must be often done;—the rough turned-up earth, after being partially dried, or otherwise benefited by the atmosphere, &c., may be further improved by having other portions of it exposed to the action of the elements. Let it, therefore, be dug over in dry weather; or, if in winter, when its surface is partially frozen, so as to bear the treading on; and at all times avoid treading upon the dry portion during this probationary process, and by-and-by you will be rewarded by the fine condition the ground is left in; and, eventually, planting and other duties may be done; at the same time taking care that nothing be done until you have contemplated in your mind's eye the ulterior effects such planting will have. In fact, before commencing planting at all, it is better to consider where the principal and subordinate walks are to be, and any other arrangement that may be deemed advisable had better be done before any extensive cropping be gone into; and first of all, the wall-trees, if there be any intended, might be planted, and the walk, edging, &c. formed, and other work done which may be properly called the foundation of the whole plan, and, like every other foundation, supports and maintains the whole superstructure; it is, therefore, imperative that it be good, and that nothing be introduced calculated to mar the affair; but as the subject is one deserving particular attention, I will append some more observations next week.

J. ROBSON.

WILLIAM AND ANN JONES.

By the Authoress of "My Flowers," &c.

"REMEMBER, remember, that thou keep holy the Sabbath day." Who among us remembers this as we ought? Those who most diligently seek to honour the Sabbath will be the most ready to confess that they come short of this strong and remarkable command. They will feel most deeply the requirements of God's holy law, and their own forgetfulness; how must it then really be with those who neither remember the charge, nor mourn over their guilty disregard of it?

It is wholesome and instructive to mark the dealings of God with men, in judgment as well as in mercy—not in the spirit of uncharitableness, but as warnings and calls to ourselves, to take heed lest we fall into the same condemnation, and to glorify our merciful God because He hath *hitherto* spared us.

William and Ann Jones have lived, with a young family growing up around them, "without God in the world." They have always been respectable, hard-working, well-behaved, honest people, and, therefore, the world thought well of them; but still, when we live in quiet, respectable defiance of God's commands, we are living without Him in the world. William Jones did sometimes go to church, to be sure, but very seldom, and his wife *never*. She lived for years at the churchyard gate, within fifty yards of the free sittings, but she never went in. She had a large family, a baby, little children to look after; she could go out to work in the fields very often indeed, but somehow, on Sundays, her cottage and her children could not be left; she had a great deal to do. It was very strange, but so it was; and she remained contentedly at home.

A lady who had known Jones and his wife from their being little children, and had a great regard for them, always employed Ann about her pretty cottage, and engaged her as a kind of "unattached" servant, to come and be useful whenever she was wanted, and a very honest creature she was; but this lady strove in vain to persuade her to keep holy the Sabbath day, and go to church. She warned, exhorted, and reasoned, but all in vain. The heart was not in Ann Jones to honour the Sabbath, and she civilly listened, but did her own way after all. Her mistress would not turn her away because of her guilty obstinacy, for she hoped in time to prevail; and she knew that more was to be done while she had influence over her than if she wholly gave her up; but she very often spoke very seriously to her, and pressed the subject home where a mother always feels it most.

"You will be punished in your children, Ann; some judgment will certainly come upon you for your determined refusal to go to church. Depend upon it the day will come when you will bitterly feel it; you have no excuse: your eldest girl can mind the children when you are out at work, and therefore once on the Sunday she might mind them while you are worshipping God."

No; Ann Jones liked to earn money, and there was no pay at the church door. She served her mistress well, because she knew her, and felt her kindness in a thousand ways: she saw and touched the money, the clothes, the broth, the gruel, &c., that she received from the arm of flesh; but she "knew not God," nor noticed the blessings He showered down upon her, and therefore she did not care to serve Him, or to go into His presence. She made His day a day of business, that she might make her own days days of gain, and went on very quietly and contentedly in her sin. One of the little boys was placed as cowboy to a neighbouring farmer, who was a steady attendant at church himself, with all his family, but who forgot, or did not consider, that he was bid to "remember" that his *servants* also should keep holy the Sabbath day; so little Willy spent *one whole year*, Sabbaths and week-days, in the midst of his cows, and was never for that whole time sent once to church.

One day, about a month ago, we suddenly heard that one of Jones' little boys was dead. Scarlet fever had attacked the child, and in a very few days he was taken from them. Before the funeral took place, another sickened and died. The third who was struck with the disease was poor little Willy, who had on that very Sunday, through the strong representations of a lady, been sent for the first time to

church; but he left his cows that day for ever, and his place knew him no more! He recovered, indeed, of the fever, and another child sickened and died while Willy was getting well; but just as he began to creep again out-of-doors, and gain strength, his body began to swell, and his mother ignorantly and obstinately disregarded the doctor's directions, until too late to save her child; and poor little Willy is now laid beside the sister and brothers who have gone before him. The poor mother is almost stunned with the force of these repeated visitations; four times within the month has the bell tolled for her; four times has death entered her dwelling; four times has the voice of the Lord sounded in her ears. Of the five children that lived at home, the baby in arms only is left; and the stillness—the solemn, terrible silence of that once noisy cottage—must agonise the hearts of the bereaved parents: it must cry louder than any earthly warning, “Hear the rod, and who hath appointed it.”

Little can be said to Jones and his wife as yet. The house is infected, and unsafe; and it needs more than a hasty passing moment to say all that can be said on such an occasion. But if this heavy chastening does not touch and teach the heart; if they “pull away the shoulder,” and “will none of God's reproof,” what can man's feeble word do for them? *This* is no light matter, easy to be misunderstood; this is no trifling circumstance, that seems to need man's hand to drive it home: it is a loud and terrible call from God's own mouth—a sharp and terrible blow from God's own hand—can they refuse to hear and understand it?

“Whether they will hear, or whether they will forbear,” let my cottage readers, yea, readers of *all degrees*, harken. This is a call; a cry to us. What are we doing on the Sabbath? We may not be minding our children, or cleaning our houses, or secretly washing our clothes; but are we *keeping it holy*? Are we “doing our own ways,” “finding our own pleasure,” “speaking our own words,” on that holy day? Are we going to church in the morning, and doing our own business the rest of the day, if we *do* go to church at all? Are we not “Jones's” in our different ways and different spheres? The letter written; the worldly book, the newspaper, read; the journey or the excursion taken; the light, thoughtless, worldly conversation indulged in; the visit paid or received, are “our own ways,” “pleasures,” and “words,” quite as much as cleaning and washing our clothes and houses. Who among us are altogether guiltless in this matter? Who among us remember that the Sabbath is declared by the Lord to be “a sign between me and you, throughout your generations: that ye may know that I am the Lord that doth sanctify you.” Who among us hallows it as it ought to be hallowed? Who among us “remembers” what the Word of the Lord hath spoken.

Let us all take home to our hearts the affliction that has fallen upon William and Ann Jones, the chastening they have received, and lay our hands upon our mouths. The rod may fall next, if it has not already done so, upon ourselves. Let us walk so that our God may visit us in mercy, and not in judgment; for self-condemnation sharpens and poisons the arrow that enters the heart. Let us remember the words of Him, our Redeemer, who came to seek and save that which was lost: “Those eighteen upon whom the tower of Siloam fell and slew them, think ye they were sinners above all men that dwelt in Jerusalem? I tell you nay: but except ye repent, ye shall all likewise perish.”

WILD BEES.

By H. W. Newman, Esq.

(Continued from page 52.)

APIS MUSCORUM, OR MOSS CARDER.

THE queen mother of this species is not so large as that of the others I have described, and she is the latest of the *Bombinatrices* in appearing in the spring. Her colour is pale yellow, very nearly the same as the moss in which she makes her nest, the body is hairy, the proboscis long, legs black; the abdomen of the male is longer than that of the female. The worker becomes cinereous as it gets older. This species is very easily taken, as they make their nest on the surface of the moss, and in most cases removed from the tread of cattle, in some quiet bank, or retired spot with a

southern aspect. One single queen commences a colony, which, in general, is few in number, although in favourable situations in Scotland, where the wild flowers of their seeking abound, I have found two hundred in number, and from that down to twenty, or even ten. This is a good species for watching the operations of the queen bee. I have easily taken many of their nests, the same way as the last described. The more cultivated and rich the country, the fewer bees of this species are found, and they vary in colour. In Scotland they are of a much darker yellow, and are called the *foggy-bee*, from *moss* being called *fog*, in that part of the kingdom.

When shooting on the Moors, in August, I have found the nest of this species very weak in numbers; sometimes only three or four workers besides the queen; one wonders how they exist in such a miserable locality; however, there they may be seen, booming along, and in a very calm day their hum is the only sound heard except the whirr of the Moorcock. When a boy, I had many colonies of these insects in my garden, and have watched their habits, which I can inform my readers are precisely the same as those already described, at least as to the males adopting a voluntary banishment and never returning to their nest. Excepting to an habitual observer, this is the most difficult species to watch, as the difference in colour and appearance is less than in any others between the workers and drones; the antennae of the latter are large, and a little curved, like a cow's-horn.

In an old orchard overgrown with moss, in Northamptonshire, I found at least twenty of their nests in the space of twenty yards square; no cattle had been in it, as it adjoined a kitchen garden, nor had there been any carts or waggons there. I had some difficulty myself to walk without treading on their nests, which may be known by being a little raised above the surface, and the moss a lighter colour. These bees are fond of the wildest of all wild flowers; they fly very near the earth, but have a very straight flight; they may be seen on the wild flowers in the deepest vallies and woods, as well as on the highest hills, and they are by far the hardiest and strongest of all their congeners. I have seen them, in most stormy weather, winging their way from flower to flower, at a time when no other bee could be seen to brave the wind and rain.

The male of this species is the latest of all in appearance, at least in our climate, seldom appearing before the end of August or beginning of September, and may be distinguished by his low flight along hedgerows, and his stopping frequently as if intending to go into the ground; this he will continue for a mile together, and, if watched, he will be seen to return to the same places more than ten times in an hour! There are two or three varieties of the *Apis Muscorum*, one of which the workers are good sized bees, with scarcely any small ones in the nest; these inhabit the West of England. I found that it does not answer the end to examine the nest of the Carders often. I found a strong nest in Northamptonshire, a few years since, and examined it repeatedly by breaking the moss; at last, a young friend of mine, wishing to have it in his garden, we went one night to take it, and discovered about one thousand ants in possession of the combs, and all the bees gone. The ants had got through the moss where it was broken and unguarded, and had overpowered the bees.

Should any of my readers wish to make experiments on any species of these insects, they should choose the end of July or beginning of August, or, if a dry, hot summer, a fortnight earlier. By far the most interesting of the species I have described are the *Apis Lucorum* and *Lapidariae*. The males of each of these are beautiful in their colours, and easily distinguished from the workers. The love of their offspring is strongly developed in all these insects. When first I took their nests, the only combs I robbed them of were those containing honey, being, like a true boy, fond of sweets; the bees that I brought with these combs generally emptied the cells and deserted them. I afterwards found that whenever I took the combs containing *young brood* in embryo, this was never the case.

(To be continued.)

COCHINS, DORKINGS, AND SPANISH.

I HAVE read the correspondence which has appeared in your paper, on the relative merits of the Cochins-China, Dorking, and Spanish fowls, with interest and amusement, not unmingled with instruction. While this discussion shows, beyond doubt, how much the interest felt upon this subject is increasing, its appearance in the columns of your little publication equally proves that we are to look, for the future, upon THE COTTAGE GARDENER as the medium of inter-communication between poultry-fanciers.

The important question is, as it seems to me, which of the varieties named is the most useful and the most profitable—and its solution depends upon several considerations. The man, for instance, who should declare, *ex cathedra*, that the race-horse is superior to the cart-horse, merely because he can gallop round him; and he who, on the other hand, should decide that the cart-horse is more useful than the racer, merely because he can draw a greater weight, are equally wrong in their judgment, or equally unfit to form an opinion. They are of different varieties, and the question being, which is the best, its true answer is, that which combines in itself the greatest number of good points with the fewest bad ones.

Taking this to be the real question in controversy among your correspondents, I request permission to state the result of my experience; for it is only by such friendly discussions as these that facts are elicited, opinions compared, and moot points satisfactorily cleared up. And, first, it is right that I should state that I am an old fancier, and have acted as judge at different Exhibitions; that I have kept Spanish fowls for many years; that an intimate friend of mine keeps nothing but Dorkings, and I have access to his poultry-yard as freely as to my own; and that I have kept Cochins, besides my Spanish, for about four years. These, and what I have had the opportunity of observing of all the breeds in the yards of many fanciers of my acquaintance, are my means of forming a judgment of the relative merits of the varieties in question.

In the next place, I apprehend that the useful and the profitable are made up of the following points:—Which are the most prolific; which the best mothers and nurses; which are the most easily reared, and attain maturity the earliest; and which are the most valuable when that maturity is reached. I propose to touch, shortly, upon each of these points *seriatim*. First, then, which of the three varieties is the most prolific? This question divides itself into two. If we look at eggs alone, the *Spanish*, though the smallest hen of the three, lays, undoubtedly, the *largest* egg. In my opinion, she lays as many of them as the *Cochin*, and consequently a greater weight in the whole, but she never sits. The *Cochin* is, undoubtedly, as "*Gallus*" candidly admits, far superior to the Dorking as a layer, and lays during a much longer period of the year, and she has this superiority over even the *Spanish*, that she lays better during the winter months, when fresh eggs are most valuable.

As regards the hatching of the eggs, the *Cochins*, in my opinion, beat both their competitors hollow. There are fewer bad eggs in proportion to the number set, and the chickens come out stronger than those of either of the other varieties. As mothers and nurses, the *Spanish*, as I have said, do not enter into the competition. The *Dorkings* are good in both respects; but I am inclined to award the palm to the *Cochins*, on account of their soft and fluffy down, and the extreme quietness and gentleness of their disposition; and they begin to lay again sooner than any other fowl. I am also most decidedly of opinion, that of all the chickens I know, none are so easily reared as the *Cochins*. The qualities of the mother, to which I have just alluded, contribute, no doubt, to this result; but even under mothers of other breeds (of which, however, I by no means recommend the use, where *Cochin* mothers are to be had) I have found them easier to rear than either *Spanish* or *Dorkings*. Between the two last-mentioned varieties, I am somewhat at a loss to decide this point, but on the whole, I think the *Spanish* perhaps less delicate in constitution than the *Dorkings*. Out of 120 *Cochin* chickens hatched this year, by *Cochin* mothers (of which I kept some inferior ones for the purpose), I did not lose more than half-a-dozen.

I have never been anything like so fortunate with my *Spanish*, nor has my neighbour with his *Dorkings*.

As regards early maturity, the *Cochins* and *Dorkings* are both superior to the *Spanish*, and I believe the *Cochins* beat the *Dorkings* too. On the 3rd of June, some chickens, weighing above five pounds each, were shown at Cheltenham, if I recollect right, by Mr. Lawton, of York; and I myself killed, in July, a cockerel hatched in March, which weighed (dead) nearly six pounds. I have never seen or heard of any *Dorkings* which attained those weights in the same length of time, and certainly *Spanish* will not do so. As table fowl, for roasting, I think there is very little difference between the three varieties, in point of quality. Fed alike, their flesh is equally good in flavour, and, no doubt, equally nutritious. But for boiling, I agree with the poulterers, that the *Dorkings* are the best, because they are the whitest in the skin, and in the leg; and this delicate white appearance is, no doubt, one reason for their selling best in the market, as Mr. Bailey says they do.

On the whole, my deliberate conviction is, that the *Cochins* will be found the most useful, and (for all purposes) the most profitable of any variety of domestic poultry yet known in this country. I have no prejudice in this matter, having good *Spanish*, as well as good *Cochins*, of my own, and the means of obtaining good *Dorkings* by the asking for; and, indeed, I was so far prepossessed in favour of the *Spaniards*, from having kept them so long, and taken so much pains to procure the best of them, that I have not yet given them up, nor do I intend doing so; and I have only given my verdict in favour of their rivals because my judgment compels me to do so. I must, however, be understood to refer to the short-legged, compact breeds of *Cochins*, and not to the coarser varieties; in fact, to compare the best of the one with the best of the other breeds.

There are some minor points which it may be well to notice, lest I should be thought to have overlooked them.

The *Cochins* are, of all fowls, the most "domestic," and the easiest to keep at home. A fence of the height of three feet will confine them; they are tractable and quiet to a degree, and are neat and pretty in their appearance. I do not at all agree with some of your correspondents, that they are greater eaters than other fowls in proportion to their weight. The farmer does not expect to feed a large *Short-horn* with the same quantity of provender that will suffice for a little *Scot*. And I am of opinion, after repeated trials, near enough to convince both my servant and myself, although not so nicely made as to justify me in giving exact weights, that, allowing for the extra size, neither old nor young *Cochins* consume more food than *Spanish* (and ducks, by the way, beat both hollow).

With regard to present estimation and value, there cannot be two opinions. To say nothing of some few extra specimens, scores of *Cochins* were sold this year, to my knowledge, at £5 each, and hundreds at £2 and £3; and I shall not be surprised if some of Mr. Sturgeon's birds bring, at his sale next week, greater prices than these. There were, undoubtedly, poultry shows, and good ones, before *Cochins* were introduced into this country; but what would our shows now be without them? Every one, I think, will admit that, in these days, the principal classes—those which attract most attention, and excite the keenest competition amongst amateurs—are the *Cochins*. This may, to some extent, wear off, as they get more common (although I cannot say I expect it); but, depend upon it, good birds will always command remunerative prices, and greater ones than either *Spanish* or *Dorkings* ever fetched, although a first-rate *Spanish* or *Dorking* fowl will still bring a good price; and I repeat that I by no means wish to be understood as intending to depreciate them when I say I prefer the *Cochins*. The latter have, undoubtedly, taken a position which, in my humble opinion, their merits will sustain for them; and this is the test of their value.

That I am not singular in the estimate I have formed, the correspondence already published by you sufficiently shows. In further corroboration of it, I refer you to the following extract from a Canadian paper (published at Toronto):—

"On looking over the list of premiums offered by the 'Agricultural Society' for the next month, I was much surprised by finding so little attention paid to a 'class' which

needs improvement here perhaps more than in any other country. I allude to poultry.

"The committee place at the head of this class, 'Dorkings' (without saying whether 'white' or 'spangled')—then follow 'Polands,' and lastly 'Large Breed'—what the 'Large Breed' may be, it is impossible to say. Surely the managers are sadly behind the age in knowledge of poultry, if they are not aware, that there are many varieties of fowls superior to the 'Dorking' and 'Poland.' The Dorking is no doubt a fine bird, as compared with the common, little, miserable objects usually sold in our markets, called 'chickens,' and possesses many good qualities—and the Poland has beauty of appearance, as well as fertility of eggs to recommend it, but into what insignificance they creep when placed near any of the Cochin-China, or Shanghai varieties. There are two families from Cochin-China,—the 'Royal,' and 'Imperial;' four, from Shanghai, the Black, White, Buff, and Brown, all of which are superior to the Dorking and Poland, in the following qualities:—First, size; second, quality of flesh; third, number of eggs; fourth, fertility of egg; fifth, hardihood of chickens; sixth, better nurses; and seventhly, value of feathers (nearly as valuable as those of geese). Add to all this, they have borne our winters, even better than our common fowls have done, and surely any person who has ever seen one of these magnificent birds could scarcely pass them over without notice.

"I have mentioned 'Shanghai's' and Cochin-China's because I am more familiar with them, than other foreign varieties, but there are other birds which have their champions; say 'Brahma Pootra' (26 lbs. the pair), 'Great Java,' 'Plymouth Rock' (18 lbs. the pair), 'Black Spanish' (superior to Poland in weight, and lay quite as well), and many others which we ought to know more about, a knowledge which can easily be obtained by a perusal of an excellent work lately published at Boston, called 'Dixon and Kerr's Ornamental and Domestic Poultry Book'—a work as superior to our old-fashioned poultry books as an 'Imperial Cochin cock' is to a half-bred Bantam."

This statement is especially valuable as bearing testimony that the Cochins will bear even a Canadian winter "better than our common fowls," and before I quit it, I will add, that I shall be much obliged to any of your correspondents who can give any information respecting the other large varieties of poultry mentioned in it, or who can tell me whether "Dixon and Kerr's Poultry Book" can be had in this country.

You will have observed that I have said nothing respecting the different varieties of Cochins; this, as you are aware, will appear in another form. In conclusion, I would add my caution to that of Mr. Wingfield (to whom, and to "Gallus," I feel much indebted for their contributions to your paper)—"to avoid all crossing." A first cross will do for the spit, but after that they soon degenerate into downright mongrels.—COCHIN.

EXPENSE OF FEEDING COCHIN-CHINA FOWLS.

JUST as I am sending off to you the result of another week's trial of the relative quantities of food consumed by Cochin-Chinas and Spanish, I read (in THE COTTAGE GARDENER of October 21st)

"The strain of strutting chanticleer
Cry Cock-a-doodle-doo!"

And I may as well answer it with the words preceding these lines, *Bow! wow!* of which there is a good deal in Mr. Cock-a-doodle-doo's paper. Let me remind *him*, and "Q-in-the-corner" too, whose answer, by-the-by, is much more (to my mind) to the purpose than poor dear Cocky's, that I have never brought into my arguments the words, which they both use—"in proportion to their size." I have nothing to do "with proportion to size." I have been discussing Cochins, as to whether they are the best fowls to keep altogether, or not, taking into consideration their merits (to which I have never been blind), and their fault of "being such large consumers of

food," which fact I can neither be written nor persuaded out of, for I have proved it, not only to my own satisfaction, but to that of every unprejudiced or uninterested person.

As an eating fowl, a Dorking *must* always be its superior. It can be got up to the same weight (even saying nothing as to flavour, and "white meat," when cooked) at a less expense than the Cochin. Surely, then, where chickens are in demand, it is a more paying fowl to the cottager.

As a layer, if a Spanish fowl, at a cost of twopence a week, can produce, say (by way of argument) five eggs, weighing 16 oz., against six eggs from the Cochin-China, weighing 12 oz., but at a cost of fourpence a week,—I leave it to the cottager to say which (if he wants eggs) will suit his pocket best.

I have been told by Anster Bonn, and others, that Cochin-Chinas "did not eat more than other fowls." Now, however, the ground is changed, and "proportion to size" comes into play. I therefore presume it is beginning to be allowed that "they do eat more than others;" and common sense may well (like the Irish echo) answer, "they do." The Cochin-China supporters have injured their own cause, in their over eagerness, by asserting too much. It is not to be supposed that large fowls, coming early into maturity, attaining great size, and laying a great many eggs, can consume as little as smaller hens, who do not equal them in some of these respects.

An old man, a great lover of poultry, asked leave, a few days ago, to see what he called "my new-fashioned poultry." His remark—"Well, Sir, if you do gets many eggs from them chaps' bodies, you *mun* put a lot of grub in their bellies"—is, I believe, quite true.

Your Cochin-China correspondents seem to be ignorant that I am a Cochin-China fancier myself, as well as they; and I may assert that I am very fond of them, but I cannot go all their lengths, and declare there is nothing like them.

This is the last letter I shall write to you on the subject. I shall retire to my perch, satisfied that time and trial will prove me not very wrong; and when I hear of Cochin-Chinas changing hands, as they are now doing—and when I am told, as I have been by an eminent Cochin-China fancier, that "It's time to get out of it," and see many such letters as some I published in my last paper to you—I begin to think I see a "something looming in the future," and that the "old uns," like rats (I do not mean this simile disrespectfully), are leaving a falling house.*

Now, sir, for the trials, which were conducted under exactly the same circumstances as the others, except that only the cock and one hen were left in No. 1, and that, though the cock in No. 2 was the same, the hens were different, but *about* the same age. As to the accuracy of the account, I pledge you my word. It may be said, my feeding is extravagant. I can only say, I went into a farm-house to-day, where they pride themselves on their poultry, and found them mixing a large tub of meal and steamed potatoes for some fine Minorca hens.

You see that similar results are again obtained—the Cochins eating double what the Spanish (and other fowls, which I will name) have done.

I have been told—"Oh! your climate certainly sharpens your fowls' appetites;" but what is food for the goose is food for the gander, and the climate that tells on the Cochin will tell on the Spanish; and the fact remains the same—"That the quantity and cost of food consumed by one is about double that of the other."

A friend of mine, who keeps only Bolton Greys, who has been trying the experiment for me of their eating, reports the result to me as "not quite twopence a week," but he does not send me the quantities. A similar report of a Golden-spangled Hamburg fancier is "about twopence a week." My own impression had been, that, as consumers, fowls might thus be classed:—

Cochins.
Dorkings.
Spanish.

And I fancied that Bolton Greys, &c., ate less than Spanish. This does not appear to be the case; and a man who keeps

* If "Gallus" alludes to the sales of part of Mr. Sturgeon's and of Mr. Andrews' stocks, we think it may prevent misunderstanding to state, that both those gentlemen are pursuing the exclusive breeding of Cochins as ardently as ever.—ED. C. G.

Spanish, and Bantams, told me he thought the latter ate as much as the former. I am inclined to differ from him. I enclose you an extract from an amateur, who, perhaps, knows more of Dorkings than anybody in England.

"I shall not be able to send you yet an exact account of what my Dorkings eat. My opinion is threepence a week, and I am almost sure you cannot do them for less. They may be kept alive for less, but not in condition. I find, on comparing my account for January, February, March, and April, that my twenty-one fowls (having the advantage of a good run, so far as herbage and casual food are concerned) cost me regularly £1 for four weeks all this time." So much for a penny a week! I have liberated my fowls now, as I consider my experiments conclusive; but if your readers are not of this opinion, only let them follow my advice of weighing out a pound of wheat or barley, and seeing how long a Cochin-China hen will be in gobbling it up. But if I can be taught how to feed my fowls well (for I am sure, not to feed them really well is no economy), I am poor enough to gladly save some money, and young enough to be willing to learn.

In taking leave, as an author, of the pages of THE COTTAGE GARDENER, I can conscientiously affirm that (having no object to gain) I have only stated what I believe to be strictly true, the result of my own experience, and that of others; and in thanking you for the courtesy and attention I have received from you.—GALLUS.

Time of Experiment—Oct. 11 to Oct. 18.

FUCHSIAS.

I FEEL disgusted at *Fuchsia spectabilis* being classed with its more handsome neighbours, for there is no beauty in it or of it. A friend of mine has had one for this three years, and it has got to the height of nine feet, without gratifying the cultivator with one of its flowers. *Fulgens multiflora* is far in advance of it. Many advise that the plants which flowered in autumn should be allowed to grow all winter; but that would not do for the cottager, or even for our practical men, for all the nursing that you can give them, the season of rest will not pass over without some defect on the plant's system, for nature will not be robbed of the rest. My plants, which have done flowering, and which I mean to flower next May and June, I have placed in their winter quarters, under the greenhouse shelves, taking care to lay

the pots on one side. This prevents the worms from intruding, and likewise keeps the pots from getting too wet, which would start them into unnatural growth, and so weaken the system of the plant. To do them justice, you should have two sets of plants, one for early-flowering, and the other for late-flowering, so by that means you may secure their blooming from May till November. In the spring, I usually take cuttings at the time I start my plants into growth; taking care to strike these in a nice, moist, dung-bed. By taking cuttings early, and keeping them potted, they will repay the cultivator for all the labour bestowed on them. The compost that I generally use is composed of one-and-a-half maiden loam, one-quarter leaf mould, and one-and-a-quarter what is termed yellow loam, from Wanstead. In this they not only grow vigorously, but retain that glossy foliage which imparts to them that contrast of flower and leaf which is so characteristic. When the plants are in a fast-growing condition, it is a great assistance to water them, say twice in the week, with a liquid-manure of sheep's dung. This makes a great addition to the size of the flowers.

In my rambles to-day I came across that much-noised-about *Fuchsia*, *Batten's Pagoda*. There is something novel in the colour of the flower, but as for showing purposes it is quite worthless; the tube is something in the shape of *Goliah*; the sepals not reflexing, and the corolla something in the shape of a soda-water bottle, never expanding at all; still, for its colour, it might have a place in a collection; but I should advise the amateur, before he buys, to see it in flower, and judge for himself. If he goes to the show-rooms, on the show days, he will be able to pick for himself. We are getting three distinct classes of *Fuchsias*. *First* is crimson with violet. *Second*, white with scarlet. *Third*, white with violet purple. The latter we have been wanting much. The following is a list of specimens of the three classes that I think would not discourage the buyer, nor disgrace the seller.

- 1.—*Alpha*; tube and vessels red, reflexes well, corolla rosy-purple.
Clapton Hero; tube and vessels glossy crimson, corolla purple.
Dr. Smith; bright crimson, with violet corolla.
Kossuth; bright crimson, violet corolla.
Resplendens; crimson-red.
Nil Desperandum; waxy bright scarlet, corolla violet-purple.
Don Giovanni; crimson tube, and sepals rosy, purple corolla.
- 2.—*Princess*; white, with scarlet corolla.
Bride; white, with vermilion corolla.
Elizabeth; blush tube, corolla rosy-purple.
Expansion; white, corolla bright rose.
Joan of Arc; white, corolla rosy-scarlet.
Conspicua; white, with vermilion corolla.
Pearl of England; blush-white, corolla scarlet.
- 3.—*Sidonia*; blush-white, with violet-purple corolla.
Sidonia superba; white, violet-purple corolla.
Delicata; white, with bright purple corolla.

R. WEATHERILL.

CEANOTHUS AZUREUS.

SEEING this beautiful climbing shrub mentioned in your notice to correspondents this week, and not remembering to have seen the culture of it in THE COTTAGE GARDENER, I am induced to send you a few lines upon it. First, as to soil. I find it likes a light garden soil, not too rich, with a little peat to start it. Secondly, as to situation. A wall facing the south; and, thirdly, as to its propagation. It can be raised from seeds, which it produces very freely. Sow them in shallow pans, in three parts peat, one part loam, and one part of well-rottened turf, with a little silver sand to keep it open. Let the pans be well drained, and placed in a cold frame or pit. Sow at the end of February, or the beginning of March. It may also be struck from cuttings in the same frame or pit, using the same soil. To effect this, take off some nice short cuttings about Midsummer, with a little of the old bark at the base of the cuttings. Use the same soil, with a little sand on the top, and place a

bell-glass over them. (I forgot to say that the seedlings must be potted off when about three inches high.) There is also another mode to obtain plants, and which I think the best and quickest way to get a fine plant, and that is to select some of the finest shoots when the wood is moderately firm, with a good leader, and of these shoots, about from nine to twelve inches from the tip, cut a notch or slit upwards about an inch, beginning from below a joint; place in this notch a small wedge, to keep it open, and chop some moss fine, and mix with it a very small quantity of peat, not too fine; place this fine moss and peat in some longer moss, so as to keep it together, then place it round the notch, and bind it up rather tightly, but not too much so; bind it up with large worsted, or what is called wool-spun, and leave a long piece from the tie, and place over this layer, as I shall call it, a common glass bottle, by driving a large nail or hook into the wall, tying a wire or strong whip-cord round the neck of the bottle, and hanging it on the nail, filled with water, and put the end of the wool-spun into the water; this will keep the moss always moist, and when you find it has made tolerably good roots, cut it half way through from the old plant, and in a fortnight you may cut it off, and pot it, and next spring plant it out where it is to remain; protect it a little for a year or two in winter, with a mat or straw; prune it as you would a rose, that is, to about two or three eyes, but above all, do not prune it until the middle of April, or you may lose your plant.—CHARLES LEVETT.

BEE-HARVEST.—1852.

SEEING that you ask for returns from bee-keepers of their experience of this year's results, I beg to forward you the annexed tabular account of my apiary. It consisted, in the spring, of thirteen stocks in various hives, wood and straw, nearly all upon the depriving system, by means of glasses, small straw caps, and small boxes. They were numbered from 1 to 13. I consider it a very bad year, both as to swarms and the amount of honey gathered. To make a comparison, I may state that last year, from nine hives I had seventeen swarms, all of which did fairly. This year I had—

- | | | |
|------|-----|---|
| June | 1. | A swarm from No. 4. |
| " | 4. | Ditto " No. 6. |
| " | 4. | Ditto " No. 10. |
| " | 15. | A second swarm from No. 4. |
| " | 19. | A swarm, not known whence. This deserted the hive a few days afterwards. |
| " | 20. | A double swarm, viz., a first swarm from No. 7, and a second swarm from No. 6, joined together, of their own accord, on a tree at the time of swarming. |
| " | 23. | A swarm from No. 8. |

So that I have seven stocks which have not thrown off a swarm. And have only added six new stocks to my apiary. My honey-harvest has been—

- | | |
|----------|---|
| June 15. | A small wooden box, taken from the top of No. 4. Removed because it contained brood, chiefly drones. The honey in it weighed 2½ lbs. |
| July 24. | A straw cap, taken from No. 2, very rich, and thick comb. Weight 13 lbs.; of which the cap weighed 1½ lbs., honey 11½ lbs. |
| " 24. | A straw cap taken from No. 11, equally good with the above, but the cap somewhat smaller. Weight 12 lbs.; cap hardly 1½ lbs., honey, 10½ lbs. |

N.B. These caps, when well filled, are supposed to hold 10 lbs. of honey. I never before had one of the kind that exceeded that weight, so that the above two are very good specimens.

- | | |
|----------|--|
| July 24. | A straw hive, No. 10. An old hive. Gross weight 23½ lbs. Hive about 5 lbs. Good honey, cut from it free from brood and pollen, about 10 lbs. |
| " 24. | A straw hive, No. 6. An old hive. Gross weight 22 lbs. Hive about 7 lbs. Honey strained from it about 8 lbs. |
| " 30. | One of this year's swarms. Yielded of pure honey, strained, 10 lbs, I. M. |

TO CORRESPONDENTS.

* * * We request that no one will write to the departmental writers of THE COTTAGE GARDENER. It gives them unjustifiable trouble and expense. All communications should be addressed "To the Editor of the Cottage Gardener, 2, Amen Corner, Paternoster Row, London."

RE-ARRANGING WALKS IN A VILLA GARDEN (Suburban).—We do not approve of either of your plans, Figs. 1 and 3 of the walk diverging and surrounding a triangle at top; much better let it proceed up the centre, as in Fig. 2, and terminate in some ornamental object, as an arbour, summer-house, piece of sculpture, or sun-dial; but a summer-house or arbour would be most appropriate. Your space is too limited to grow many vegetables, under any circumstances; therefore, appearances ought to guide you as to its disposal. Avoid all tall things, as Asparagus, Peas, Jerusalem Artichokes, and Scarlet-runners, all of which you will buy cheaper than you can grow, and devote what space you have to lower-growing crops. A walk by the side of a wall is not necessarily injurious to the fruit-trees trained thereon, provided a suitable description of soil be afforded the roots underneath the walk, the substance of which ought to be thin. Trees often do better so treated than when a heavy vegetable crop contends with them for the uses of the border. See an article by Mr. Robson, on Suburban Gardens, in to-day's paper, which will be followed by others bearing on the same subject.

PHYTOLACCAS (T. W.).—Many thanks for the seeds of *Phytolacca decandra*, which are quite true. The plant, however, will grow full five feet high, if you can preserve it through the winter. Damp is worse for it than frost, and it is always a safe plan to grow a few from seeds every year or two. The seeds will keep better in the berries, and also on the stalks, all the winter; and about the end of February is the best time to sow them, and then to sow the berries just as they are. They want the same treatment as ridged Cucumbers, or Capsicums, or Tomatoes, and no soil can be too rich for them to flower in, and no soil can be too poor for them to stand well against the frost. Hence, to grow them to perfection, we ought to treat them as biennials. Sow them at the end of April, in a close, cold pit; nurse them in pots till July; then plant them out for six weeks; then take them up and pot them, and keep them over the winter with the *Humeas*, and next May plant an avenue, or long border, with *Humeas* and *Pocans* alternately. By so doing you will make a stir in that part of the country. Three, five, or seven plants of this *Phytolacca*, planted in a group in front of a tall mass of evergreens, in very rich soil, and at some distance from the walk, would have a splendid effect.

FLOWER-GARDEN (T. F.).—You have distributed the colours well, but the plants do not match as they ought to do for this style; 3 and 4, for instance, purple *Petunia* and blue *Lobelia*, when in their prime, will look like a carriage-horse and a Shetland poney yoked together; both in high condition, but not a match, as all pairs ought to be, whether carriage-horses, flower-beds, or flower-pots. To a practised eye, a man going down the road with a hobnailed shoe on one foot, and a tight Wellington on the other, would not look more strange than a *Petunia* and a little *Lobelia*, side-by-side, "to match!" *Salvia chamædryoides* is the nearest to suit No. 3 bed; 13 and 15 ought to change places with 11 and 12, being lower, and of better habit, next the house; 1, 2, 5, 8, 9, 10, and 14, could not be done better, and there is not a plant in the catalogue to suit No. 6, except *Cineraria amelloides*, to carry out your own way of matching in blue and purple. To exemplify all this, and as a good example of covering such a space, we shall engrave your plan some day. The *Vine* will do very well as you propose to train it, but beware of the shoots being crowded.

FLOWER-GARDEN (J. H.).—The best-shaped beds are circles; next best, ovals; third best, long, narrow beds, with some graceful curves in the outline; and the fourth best is, for you, what you think the best yourself; and so with all the world besides. In nine cases out of ten the shapes of flower-beds are determined by the size, situation, and laying-out of the piece of ground. You marked a line from the circle in front of the offices to the oval at the farthest end, a single bed placed on that line would spoil the effect of your garden, on paper, whatever the shape might be. If you could place two other circles opposite the present two, and a half-moon-shaped bed in the middle, between them, that would be right.

SCARLET-FLOWERING PEACH (R. K.).—We never say where such and such plants can be bought. We said once or twice that Mr. Appleby could get any plant that was on sale in Europe or America for anybody who offered to pay for it. The best way is to give your commission, in all such cases, to the nearest nurseryman, and he can, if he chooses, supply you with plants free of all carriage, &c., as cheap as you could buy them in London. Your bookseller does the same thing every week in the year with this COTTAGE GARDENER. Doing things in a business way, in a business country like England, is always the surest and cheapest way in the long run. We are intending to have excellent lists of all the best shrubs and trees this winter; for we can now afford space for them.

"ORCHARD" will see much of his question answered to-day, in a paper on Fruit and Vegetable Culture. The most noted counties for the *Damson* are Shropshire and Cheshire. In the part where we write (Cheshire) every cottage gardener has them blended with the thorn hedges; and many, in good seasons, pay their rent with these alone. They delight in sandy soil, although we find them occasionally growing in stiff soils. Any nurseryman, living by the rail in those counties, would supply you. Plant directly, above the ground level; use in your stiff soil some road scrapings, or loose material. To your *Apple* list add *Beauty of Kent*, *Chapel Apple* (to be had in any Lancashire nursery), *Dumelow's Seedling*, or *Normanton Wonder*. To your *Pears* add *Jersey Gratioli*, *Dunmore*, *Beurre de Capianmont*, and *Beurre Diez*. You may put the rubble between the roots, in stations formed hard, with a convex surface.

"STUPID."—Your paper will be noticed in due course.

LARGE PLANTS OF PELARGONIUM DYING OFF.—R. F. had some splendid plants of the fancy kinds last summer; dense bushes, the heads fully four feet in diameter, and a mass of bloom for four months.

They have been managed exactly as detailed in this work, and by which they have previously given great satisfaction. They were allowed to get rather dry, were pruned back as usual, broke fresh shoots moderately strong; were fresh potted, and stood still; and now several of the best of them are gone, the main stem decaying just before the skeleton of the top branched off. Now, will any of the learned say what this is owing to? We sometimes think *age*, the mass of flowers they produced, the length of time they bloomed, &c.; but then some of their neighbours underwent all these conditions exactly, and yet seem right enough. When we look on the beautiful skeletons of these defunct plants, and think what they might have been next season, when clothed with flowers and foliage, we cannot help wishing that a plant doctor, of universal curing abilities, had seen and prescribed for them. The plants were more than three years old.

CLIMBING PLANTS FOR GREENHOUSE (J. R.).—We are almost afraid to enter into detail about *Passion Flowers*, *Mundevilla suaveolens*, *Tucsonia pinnatistipula*, *Tecoma jasminoides*, &c., as considerable attention has lately been bestowed upon them. The pruning of most of them was also given. In respect to your inquiries on that subject, as the plants have not yet reached the top of the house, you may shorten the ends a little now of all, and prune in any side-shoots of the *Passion Flowers*. The *Glycine* will bloom on ripe young wood, and also on spurs, just like a currant. *Tropaeolums*, of most kinds, will die down in winter; at least, if the house is not warm they will not succeed. *T. Lobbianum* will do well in a temperature of 50°, and bloom all the winter. As to *pots*, you must proportion the size according to the space you wish the plants to occupy—say from twelve to eighteen inches in diameter. Do not shift them now, however, if these plants are in small pots; wait until the end of March. See what Mr. Fish says to-day.

DESIRABLE HARDY SHRUBS (Ibid.).—We could serve you better if you told us your purpose. The following are useful:—*Deciduous*—*Aesculus carnea* and *pavia*; *Azalea*, Ghent varieties, &c.; *Amelanchier florida*; *Andromeda buxifolia*, speciosa requires heat; *Chimonanthes fragrans*; *Calycanthus floridus*; *Cotoneaster* of kinds; *Crataegus heterophylla*, *pyrifolia*, *coccinea*; *Deutzia scabra*; *Daphne mezereum*; *Gaultheria shallon*; *Hibiscus syriacus variegatus*; *Indigofera violacea*; *Halesia tetraptera*; *Philadelphus grandiflorus*; *Pyrus spectabilis*; *Ribes sanguineum speciosum*; *Spiraea grandiflora Lindleyana*; *Symphoricarpos racemosus*; *Syringa Josikea*. *Evergreens*.—*Adesmia viscosa*; *Berberis aquifolium*, *Darwinii*, &c.; *Benthamia fragifera*; *Bupleurum fruticosum*; *Cotoneaster rotundifolia*; *Daphne cneorum*; *Helianthemum* of kinds; *Kalmia angustifolia*, &c.; *Ligustrum lucidum sempervirens*; *Yucca filamentosa superba*, &c.; *Vaccinium flore coccinea*; *Viburnum tinus*, *hirtum*, &c., with *Rhododendrons*, common and hybrid; *Magnolias*, if the station is warm and sheltered, and for beautiful ever-green effect, have such *Junipers*, *Cupressus*, and *Arbor Vitæ*, as Mr. Appleby has, and will recommend.

ONE-THOUSAND-AND-ONE QUESTIONS (John).—Put them one at a time, and we will answer them, although, if you refer to the indexes of past volumes, you will find all the information you seek. To reply to the whole at once would fill a column.

CIDER-MAKING.—*Somersetensis* will be much obliged by an account of the method of making Cider in Gloucestershire or Herefordshire. Will some of our readers favour us with a reply?

CELERY BLIGHT (A Subscriber).—The blight, or parasitical fungus, which covers both the upper and under sides of the leaves of your Celery plants, is probably one of the numerous species of either *Aecidium* or *Uredo*. Dust the leaves with a mixture of quick-lime and sulphur—two parts of the first to one part of the latter—and oblige us with a statement of the result.

NAME OF ORCHID (T. F. G.).—This, which we did not recognise from so small a piece, we find is *Tillandsia stricta*, a beautiful species from the West Indies and Brazil. You will find an account of it in our sixth volume, page 386.

FOWLS FOR EGG-PRODUCE (W. E. J.).—If you wish for fowls that seldom or never desire to sit, so that you may avoid the trouble of chicken rearing, keep the Spanish. They lay larger eggs than the Shanghai, but the latter lay quite as many in the course of the year, and will lay throughout the winter, if carefully managed. By *Shanghai* we mean what are erroneously, though usually, called *Cochin-Chinas*.

WHITE SHANGHAI FOWLS (N. J.).—They are sometimes pure white, but usually with a considerable admixture of grey feathers in their plumage. We have seen specimens of them larger than of any other colour. They are feathered on the legs. Fashion is too like a butterfly for us to say where she is likely to settle. If any one near Leeds, or York, has any of the White Shanghaes to sell, they will oblige by writing to Mr. John Noble, Boston Spa, York.

PEAT (Y. Z.).—You may apply it with advantage to your *Hydrangeas*, the flowers of which it may render blue; but to none of your other plants or crops will it be of any benefit. It is invaluable to all American plants, and we should think some florist will gladly give you manure in exchange for it.

REGULATION OF TIME.—*Expertus* and the *Rev. F. H. S.* have kindly pointed out, that in our weekly Calendar for October the clock is erroneously put as "before the sun," instead of "behind."

CAMELLIA BUDS FALLING (Emma).—The fact of your Camellias being in the dry air of your sitting-room is quite sufficient to account for this catastrophe. If the soil is wet, and the air dry, or the reverse, buds are always liable to be shed, on account of the disproportionate action of the leaves and roots.

COVENT GARDEN (W. H. H.).—When H. spoke of *Cabbages* and *Cauliflowers* as at so much "per dozen," he used the market phrase, which is there understood as "per dozen bunches." The Potato you mention, *Martin's Seedling*, is a good Potato, but smaller and later than we like to recommend.

DUCKS NOT LAYING (A. S.).—They do not usually lay except in the spring.

DOUBLE-GLAZED LIGHTS (A. J. F.).—As you did not have the inner

glass lapped, and consequently the moisture gets in between the glasses, and condenses so as to cause a serious drip, we recommend you to have the joinings of the inner panes closed, by painting them, by means of a very small brush, with liquid putty. We say "a very small brush," because the paint should not extend over the glass so as to obstruct the light.

SLOPING BANK (Co. Cork).—Unless you have this faced with a mixture of coal tar and dry powdered lime, so as to have a face impervious to ascending damp and weeds, you must fail in training fruit trees upon it. If you have such a facing, then upon it must be a wooden trellis, on which to train the trees.

VINE BORDER (A. B. Y.).—When you made this four feet deep, you made it full two feet too deep. If you had referred to what has been repeatedly said in these pages upon the subject, you would not have thus dangerously erred. The turf and sand, with some bricklayers' rubbish, would have been best without any stable manure. We cannot tell you how far to cut back your Vines without knowing how strong they are, and whether you purpose to cultivate on the spur or single-rod system.

DARK ROSE (S. S. S.).—Either *Elegans* or *General Changarnier* will suit your purpose. *Ivy* will grow very well on the north side of your house. It entirely covers a similar frontage in a house we see daily. Plant the *Irish Ivy*. Keep the roots moist in spring and summer, by covering them with mulch, as the soil is so shallow.

CHOICE OF SHANGHAI FOWLS (Brixton).—As we are convinced there is no such variety as the *Cochin-China*, we shall always in future, except inadvertently, speak of them as *Shanghai*. Of Mr. Sturgeon's breed there can be no doubt, of the other we know nothing. Never mind, however, how excellent the original stock may have been, for they may be spoiled by bad intermixtures and bad keep. Never buy the cock and hens from the same yard. This breeding-in will of a certainty give you chickens inferior to their parents.

BEE FLOWERS (Bromley).—Write to *J. H. Payne, Esq., Bury St. Edmunds*. Your other queries next week.

LOVELL SHANGHAI FOWLS (Iota).—No other description of these can be given than that they are smaller-framed birds, and altogether more delicate-looking than the usual large Shanghaes. They are feathered-legged, and ought to be buff-coloured.

KITCHEN GARDEN (A Constant Subscriber).—You will see what Mr. Robson says in his notes to-day, and in some future numbers. If he does not touch upon any subject on which you require information, write to us again.

WEEKLY CALENDAR (Cymro).—The first column states, from various works on Natural History, the occurrences usual at the time in animal or vegetable nature. The two instances you quote refer to the arrival of the Wood-pigeon, and to the Gull leaving the seashore for inland feeding ground.

SHANGHAI FOWLS (Ovum).—February is the earliest month in which to commence placing their eggs under a sitting hen; and it is of little use to continue doing so after the beginning of June. Eggs have travelled more than 300 miles, without injury, but their safety depends on the packing.

FERNS FOGGING OR DAMPING-OFF (M. D.).—To prevent this, give less water and more air; and sprinkle about a quarter-of-an-inch in depth of silver sand, over the top of the soil.

FEEDING COCHIN-CHINAS.—*J. H. P.* says—"I wish to bear my testimony in corroboration both of 'B. P. B.'s' statement, in last week's number of THE COTTAGE GARDENER, and that of 'Q-in-a-Corner.' I can say with the former, that my young fowls have always been exceedingly fat, many of the cocks now weighing nine pounds each; and, as regards their productiveness, it is extraordinary, for one of my March pullets has already laid upwards of fifty eggs. Neither can I discover that they are such enormous eaters as has been represented. My number is two or three above fifty, consisting of five old fowls, and the remainder chickens, chiefly hatched in March and early in April; their consumption now is one bushel of barley and one bushel of middlings, per week, which I purchase for five shillings, making their cost sevenpence over a penny per week each. I should also say, that they are always kept confined to a space of 180 square yards, green food from the garden is thrown to them occasionally, and their porridge is mixed with water in which meat has been cooked."

CELSIA CRETICA.—A clergyman at *Cloyne*, in Ireland, says—"Many thanks for your information relative to the *Celsia Cretica*; it agrees with what my friend says, who is a most enthusiastic botanist, and is at present collecting the different species of fungi about this, and has found some beautiful ones. Shall I ask him to send you sometimes a paper on the botany of this part of Ireland, if you thought it would be useful for THE COTTAGE GARDENER? [Yes, if popularly written.] The *Celsia Cretica* is common in different fields about this, growing in great luxuriance. I always fancied it was a *Verbascum*. I see an inquiry in last number what *Melidiores* are?—*Maladores* must be meant. They are a species of Persian *Ranunculus*, and make a very handsome bed of mixed colours. I send you some seed, in case you may not know them. If you sow them now in a pot, in greenhouse or hotbed, they may be sufficiently advanced to plant out and blossom in spring. I do not think they are much known, even by seedsmen. I enclose you a flower of one remaining in bloom; it is, however, an ugly one, and rather single; some are beautiful. They hybridise so freely among themselves, you can judge the character of the flower by that."

NAMES OF PLANTS (Rev. R. M. Evans).—Your *Sabia* is *S. Grahamii*. (*Quidem*).—Yours is *Ceanothus azureus*. (*A. M. L.*).—Yours is *Leonotis leonurus*, by some called *Phlomis leonurus*.

LONDON: Printed by HARRY WOOLDRIDGE, Winchester High-street, in the Parish of Saint Mary Kalendary; and Published by WILLIAM SOMERVILLE ORR, at the Office, No. 2, Amen Corner, in the Parish of Christ Church, City of London.—November 4th, 1852.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last twenty-five years, the average highest and lowest temperatures of these days are 50.1° and 35.6° respectively. The greatest heat, 63°, occurred on the 12th in 1841; and the lowest cold, 15°, on the 16th in 1841. During the period 88 days were fine, and on 87 rain fell.

BRITISH WILD FLOWERS.

WATER LILIES.—NYMPHEACEÆ.

CHARACTERS OF THE ORDER.—Sepals and petals numerous, overlapping each other like tiles, passing gradually into each other, the former not falling off, the latter inserted upon the disk which surrounds the pistil. Stamens numerous, inserted above the petals into the disk; filaments petal-like; anthers joined their whole length to the filament, bursting inwards by a double longitudinal cleft. Disk large, fleshy, surrounding the pistil either wholly or in part. Ovary many-seeded, many-celled, with the stigmata radiating from a common centre upon a sort of flat pitcher-shaped cup. Fruit a many-celled capsule. Seeds very numerous, attached to spongy partitions of the seed-vessel, and enveloped in a jelly-like covering. Albumen floury. Embryo small on the outside of the base of the albumen, enclosed in a membranous bag; cotyledons leaf-like. Herbs, with shield or heart-shaped fleshy leaves, growing in quiet waters.

NYMPHÆA.—WHITE WATER-LILY.

GENERIC CHARACTER.—Calyx below seed-vessels, of four large, leathery, oblong, permanent leaves, coloured on the upper side. Petals numerous, oblong, placed in several rows upon the base of the germen. Nectary globose, in the centre of the stigma. Stamens very numerous, flat, placed on the germen above the petals; the outermost gradually broadened. Anthers line like, of two parallel cells, closely attached, in their whole length, to the inner surface of the upper part of each filament. Germen stalkless, globose. Style none. Stigma globe-like, stalkless, of numerous rays, pointed and separate at the extremity, permanent. Berry leathery, scarred, of as many cells as there are rays; at length internally jelly-like and pulpy. Seeds numerous in each cell, roundish. Large, smooth, aquatic, perennial herbs.

Stem none. Leaves floating, on long footstalks, heart-shaped or shield-shaped, entire or toothed. Flowers on long simple stalks, large, white, red, or blue, closing, and sinking more or less below the surface of the water, at night.

NYMPHÆA ALBA: Great White Water-lily; Water Rose; Water Can; Can Dock; Watersocks.

Description.—It is a perennial. Root tuberous, often as large as the human arm, putting forth numerous, widely-extending rootlets, with fibrous ends. Leaves floating on the surface of the water, about nine inches wide, oval-heart-shaped, the notch at the base deep, edge of the leaf unnotched, and raised above the water, smooth, veins on the underside not prominent. Leaf-stalks and flower-stalks cylindrical, full of cells within. Flowers large, from four to six inches across. Petals white, from sixteen to twenty-four in number, in two or three rows, wider than the sepals, or leaves of the calyx, egg-shaped, outer ones with a green streak down the back, approaching in their structure more to that of the calyx, as the inner petals do to the structure of the stamens, becoming gradually smaller. Sepals smaller than the outer petals, being about two inches long, and one inch wide, egg-shaped, blunt, spreading, streaked, but shining and smooth, yellowish-green on the outside, with a white edge, within-side white, sometimes tinged with red. Stamens usually about seventy in number, but sometimes more than eighty; filaments short, thick, broad-spear-head shaped, fast to the side of the germ, white, but inner ones yellow and bent inwards; the outer resembling the inner petals. Germ roundish. Pistil without style, stigma divided into about sixteen rays, about ten lines in diameter, which bend back, each ray corresponding to a cell in the germ. Berry globe-shaped, warted with the remains of the filaments, about sixteen-celled, with a very large concave, grooved, scolloped-edged stigma like the Poppy; rind thin and leathery, jelly-like pulp in the cells, which dries up to a spongy substance. Seeds very numerous, flattened globe-shaped, with a blunt angle on one side, yellowish-green, smooth, and shining, buried irregularly in the pulp.

Places where found.—In slowly-flowing rivers, and ponds never without water.

Time of flowering.—July.

History.—The name of *Nymphæa* is aptly applied to this beautiful genus of water-inhabiting flowers, as realizing the idea of the heathen poets, that the waters are tenanted by nymphs or spirits. The flowers arise and open as the sun attains power in the morning, but they close towards the evening, and either recline upon the surface, or sink within the water.

Those virgin Lilies, all the night
Bathing their beauties in the lake,
That they may rise more fresh and bright,
When their beloved Sun's awake.

There is no doubt but that the flower rises out of the water during sunshine that the pollen may perform its fertilizing office; and the same providential wisdom has so arranged that the seed-vessel, as it ripens, becomes heavier than the water, and sinks to the bottom to deposit its seeds in the mud. The tuberous roots are employed to dye a dark brown by the Irish and the inhabitants of the Isle of Jura. Swine eat it. Goats are not fond of it, and oxen as well as horses reject it. *Aphis aquatilis*, and *Leptura aquatica* live upon it. Its use in medicine is now abandoned. (Smith. Martyn. Lindley. Withering.)

WE first saw the noble Pampas Grass (*Gynerium argenteum*) in the garden of the Horticultural Society, last September, coming into flower, and in the first week of October we called at Kew, and found it there in full bloom, planted out on the grass near the plant houses. There were twenty-six or twenty-seven flower spikes on this fine plant, and notwithstanding the general opinion that more species are to be seen at Kew than in any other collection in this country, after seeing most of them, we came to the conclusion that the Pampas Grass was the best plant they had in this national garden, considering that every cottage gardener in the kingdom could grow and flower it as well as they do at Kew.

From that day we made up our mind to put all resources into active play, in order to provide plants of it to try the experiment. With the exception of the electric telegraph, these means were put in force, and the "returns" we shall show presently; but first of all let us say, that the tops of the flower-stems of this grass stood full nine feet high, that the panicles or flowering parts were from eighteen to twenty and twenty-four inches long, the plumes, or feathery parts, falling gracefully on one side, and as the wind moved them about, two distinct shades were produced in undulating waves, a silvery hue passing over a warm cream-coloured ground. It was late in the afternoon, after a shower, and the sun was strong upon them, and never were we more delighted with the sight of a flower. Sir W. Hooker, Dr. Wallich, and two other foreigners were there, and seemed to admire it as much as we did. It was only a few days before this that Sir W. Hooker wrote as follows, "Who does not, among the many friends of Dr. Wallich, rejoice to learn that this distinguished and most liberal botanist has been recently honoured by his Danish Majesty in being made a Knight Commander of the Order of Dannebrog," Who, indeed! And who does not, among the many friends and admirers of these two distinguished and most liberal botanists, "rejoice to learn" that they are both of them looking hale and hearty, and in as high spirits as if their healths had never been impaired, the one in eastern climes, the other by harassing duties inseparable from his calling during the vast changes and improvements which were effected in this garden during the last few years.

There are several plants of the Pampas Grass round Edinburgh and London, but none on sale. It comes into flower in Scotland earlier than in England, but no one has yet succeeded in getting seeds from it in either country. The only place where seedlings of it are likely to be ripened, is the Glasnevin Botanic Garden, in Dublin, and if they are there ripened, the curator, Mr. Moore, ought to make a good harvest of them, as every one on this side of the water is on the look out for the plant.

Of all the plans that we can hear of for increasing it in other ways, that by Mr. Pince, of Exeter, this season, is the most likely to succeed. Instead of allowing his plants to run to flower, he cuts out the flower-stalks as soon as they appear, and thus causes the strength that

would be expended in producing so many flower-stalks, up to nine or ten feet high, to be reserved for the crown or body of the plant for the increase of side-shoots, as one may say; then, by stripping off some of the lower leaves, as they do with suckers of the Yucca or Pine-apple, and by "earthing up" the soil against these side-shoots, he expects them to root before he removes them from the stool, and the idea is very feasible indeed, and no one will be more pleased to hear of a successful issue than THE COTTAGE GARDENER.

We have suggested that Mr. Tweedie should be written to for another supply of the seed of this most desirable grass, but now it appears that no one in this country knows where he is, or whether he is dead or alive, or is off to "the diggings." We see no other course, therefore, but to get some parties to club together and secure the services of Mr. Fortune to go out to Paraguay to establish another new plantation of tea in the far west. No man knows better how to humour the natives of a tea country than Mr. Fortune, and here is a country that has been tabooed for the last forty years as much as ever China was—larger than Great Britain, and as productive in its own peculiar tea or Maté (*Ilex paraguayensis*) as the far-famed tea districts in China, where he gained his well-earned laurels. Let Mr. Fortune be once introduced to his excellency General Urquiza to spin a yarn about tea and cotton plantations,—how the Celestials and Yankee-doodles might be outwitted in colouring tea and teasing cotton along the tributaries of the Parana and Uruguay—and we pledge our best gold pen that the brave old soldier will have more cause to rejoice at his own "decree," by which this, the finest country in the western world, is now opened "to the sails of all nations," than by all that Sir Charles Hotham and the French Chevalier, or the like of them, could say till Christmas.

All this settled, and the plains of Buenos Ayres rumaged for a large supply of our Pampas Grass, see the thousand chances there would be for new plants in Paraguay itself, where no plant collector has ever yet set a foot. Let us have a joint-stock enterprise into this new country, and not rest satisfied till we have *Cavendishia nobilis*, and such Rhododendron-like plants as common in the trade as conifers. Let our India experiments in raising cotton be repeated on the banks of the sluggish Parana and Uruguay, and if we do not like their holly tea, Mr. Fortune knows where and how to get the real thing for them, and for those who know best how to go about the working of both concerns without recourse to "Uncle Tom's" fraternity. B.

TUESDAY, November the 2d, was a great day for Shanghae Fowls and their keepers, for never were a more beautiful lot exposed for sale than on that day, and never before did they realise such prices. We refer to the sale by auction at the Baker-street Bazaar, and by the effective hammer of Mr. Strafford, of the superfluous stock, and the chickens of 1852, of Mr. Sturgeon's celebrated fowls. There were 150 lots, and these realised

£606. Such a result is quite an epoch in poultry-keeping, and refutes beyond all dispute the opinion entertained by *Gallus* and others, that the taste for Shanghae fowls is on the decline.* It is such an event that we shall reprint the catalogue entire, affixing the price given for each lot, with a few comments upon some of them. It is a record and a standard for poultry keepers worth preserving.

Great judgment was shown in the whole of the arrangement. The birds, for the most part, were sold singly; none but good birds, though necessarily varying in excellence, were included in the lots; there was every facility given for examining them, and every information relative to each lot that a breeder might desire to know. There was no puffing attempted, the auctioneer knew that the birds spoke for themselves—they were from one of the best yards in England, and from that only. The result is well told by the exclamation of a foreign gentleman who came in just as the hammer fell on lot 12—“Seven pounds! Can that be for *von hen!*”

That our readers who were not present at the sale may extract from the catalogue as much instruction as we can aid them to, we will observe that nearly every pullet, unless we have otherwise stated, was in colour buff—buff of medium depth—and the feathers were not glossy, but of a soft surface, very much like that of rice paper. Those of our readers who are sufficiently entomological to know the Drinker Moth, a moth very common of an evening late in the summer, will at once be able to realise the colour of some of the best pullets at this sale. We were glad to observe that the necklace, which was strong and dark on many of the pullets, did not depreciate their value. Thus, lot 78 fetched eleven pounds, although it had a necklace, and so far from thinking it objectionable, we think it adds to the bird's beauty. Surely, nothing but the difficulty of getting rid of it ever suggested its removal being desirable.

All the chickens, it will be observed, were the progeny of one or other of three cocks, and as poultry stud books are sure to be kept, we give their names and performances.

“THE PATRIARCH” took the second prize at Birmingham in 1850, when his chickens took the first prize and medal for unusual merit; first prize at Bradford and Huddersfield, in 1851; and the Cheltenham Cup, at Cheltenham, in 1852.

“SAM” took first prize and medal for unusual merit, at Birmingham, in 1851.

“JERRY” took the Gloucestershire Cup (value 5 gs.), at Cheltenham, in 1852.

“The chickens are bred from hens which shared the honours with the above cocks, and others of equal merit. No inferior hen was bred from.”

“The ages are given as near as the keeper can tell; but it is impossible in such a number to be exact as to the age of the chickens, or the hens from which they are bred.”

Lot 1. *Pullet* by Sam, hatched third week in March; 2*l.* 4*s.* 2. *Pullet* by Jerry, hatched third week in March; 2*l.* 10*s.* 3. *Cockerel* by Sam, hatched first week in April; 2*l.* 15*s.* 4. *Pullet* by Jerry, hatched first week in March; 4*l.* 10*s.* 5. *Cockerel* by Sam, hatched first week in March; weighed 10 lbs. on the 13th of October; 3*l.* 12*s.* 6. *Pullet* from Mr. Moody's stock; 1*l.* 5*s.* 7. *Pullet* by Jerry, hatched first week in

March; 3*l.* 5*s.* 8. *Cockerel* by Patriarch, hatched second week in March; 7*l.* 9. *Pullet* by Sam, hatched third week in March; weight 7 lbs.; 3*l.* 10*s.* 10. *Pullet* by Sam, hatched third week in March; 4*l.* 10*s.*

OLD BIRDS.

11. *Hen* from Mr. Moody's stock, and has weighed over 10 lbs.; 4*l.* 12. *Hen*; took first prize and medal at Birmingham, in 1851; 7*l.* 13. *Cock*; took first prize and medal at Birmingham as a chicken, in 1851; 6*l.* 6*s.* 14. *Hen*; weighed on the 13th of October, in full moult, 10 lbs.; 6*l.* 15. *Hen*, bred in 1851; 1*l.* 15*s.* 16. *Hen*, imported in 1852; 2*l.* 7*s.* 6*d.* 17. *Hen*, bred in 1851; 2*l.* 2*s.* 18. *Hen*, bred in 1851; highly commended, as extra stock, at Halifax; 6*l.* 6*s.* 19. *Hen*, bred in 1851; 2*l.* 15*s.* 20. *Hen*, bred in 1851; highly commended, as extra stock, at Halifax; 4*l.* 15*s.* 21. *Hen*, bred in 1851; highly commended, as extra stock, at Halifax; 8 lbs.; 4*l.* 4*s.* 22. *Hen*, bred in 1850; 2*l.* 15*s.*

WHITE COCHIN-CHINAS.

23. *Cock*, purchased, with a hen, of Mrs. Herbert, at Birmingham, in 1851, and selected by Mr. Sturgeon for the best pair of white birds shown, he having the first choice of her prize and medal birds; 2*l.* 13*s.* 6*d.* 24. *Cockerel*, bred from Lot 23, and hen referred to as purchased with him; 4*l.* 15*s.* 25. *Cockerel*, ditto, ditto; 1*l.* 14*s.* 26. *Cockerel*, ditto, ditto; 3*l.* 27. *Cockerel*, ditto, ditto; 3*l.*

CHICKENS OF 1852.

28. *Cockerel* by Sam, hatched first week in April; weighed 9½ lbs. 13th of October; 3*l.* 10*s.* 29. *Cockerel* by Jerry, hatched first week in March; weighed 9 lbs. 13th of October; 6*l.* 15*s.* 30. *Pullet* by Sam, hatched third week in March; 3*l.* 3*s.* 31. *Cockerel* by Patriarch, hatched first week in March; weighed 11½ pounds. 13th October; 10*l.* 10*s.* 32. *Cockerel* by Sam, hatched second week in April; 1*l.* 15*s.* 33. *Pullet* by Patriarch, hatched first week in March; 5*l.* 5*s.* 34. *Pullet* by Sam, hatched third week in March; 7*l.* 7*s.* 35. *Cockerel* by Jerry, hatched third week in April; 2*l.* 5*s.* 36. *Cockerel* by Patriarch, hatched third week in April; 2*l.* 2*s.* 37. *Cockerel* by Sam, hatched second week in April; 4*l.* 10*s.* 38. *Pullet* by Jerry, hatched second week in March; 7 lbs.; 6*l.* 6*s.* 39. *Pullet* by Sam, hatched third week in March; 5*l.* 40. *Cockerel* by Sam, hatched second week in March; weighed 9½ lbs. 13th of October; 2*l.* 15*s.* 41. *Cockerel* by Patriarch, hatched third week in March; 4*l.* 10*s.* 42. *Pullet* by Jerry, hatched second week in March; *Pullet* by Sam, hatched third week in March; 3*l.* 15*s.* 43. *Cockerel* by Patriarch, hatched third week in April; 2*l.* 2*s.* 44. *Cockerel* by Jerry, hatched third week in May; 2*l.* 5*s.* 45. *Pullet* by Jerry, hatched second week in April; 3*l.* 5*s.* 46. *Pullet* by Sam, hatched first week in April; 7*l.* 15*s.* 47. *Pullet* by Patriarch, hatched third week in March; 6*l.* 6*s.* 48. *Cockerel* by Sam, hatched third week in March; 4*l.* 49. *Cockerel* by Patriarch, hatched second week in April; 3*l.* 6*s.* 50. *Cockerel* by Sam, hatched first week in March; 2*l.* 10*s.* 51. *Pullet* by Sam, hatched third week in March; weighed 8 lbs. 13th of October; 6*l.* 6*s.* 52. *Pullet* by Sam, hatched third week in March; 7*l.* 7*s.* 53. *Pullet* by Sam, hatched first week in April; *Pullet* by Patriarch, hatched first week in April; 6*l.* 15*s.* 54. *Cockerel* by Jerry, hatched third week in April; 4*l.* 4*s.* 55. *Cockerel* by Jerry, hatched third week in March; 2*l.* 2*s.* 56. *Cockerel* by Jerry, hatched first week in April; 4*l.* 10*s.* 57. *Cockerel* by Jerry, hatched third week in April; 8 lbs.; 4*l.* 58. *Cockerel* by Sam, hatched second week in March; 9 lbs.; 5*l.* 59. *Pullet* by Jerry, hatched second week in April; 8 lbs.; 4*l.* 60. *Cockerel* by Patriarch, hatched third week in March; 4*l.* 4*s.* 61. *Pullet* by Jerry, hatched third week in March; 5*l.* 12*s.* 6*d.* 62. *Pullet* by Patriarch, hatched first week in April; *Cockerel* by Sam, hatched second week in April; 6*l.* 10*s.* 63. *Pullet* by Sam, hatched third week in March; *Cockerel* by Jerry, hatched third week in April; 5*l.* 64. *Pullet* by Sam, hatched third week in March; 2*l.* 15*s.* 65. *Cockerel* by Patriarch, hatched third week in March; 3*l.* 10*s.* 66. *Pullet* by Patriarch, hatched second week in April; *Cockerel* by Sam, hatched second week in April; 5*l.* 15*s.* 67. *Cockerel* by Patriarch, hatched third week in April; 3*l.* 7*s.* 6*d.* 68. *Cockerel* by Jerry, hatched first week in May; 1*l.* 15*s.* 69. *Pullet* by Patriarch, hatched second week in April; 5*l.* 70. *Cockerel* by Sam, hatched second week in April; 1*l.* 10*s.* 71. *Pullet* by Jerry, hatched first week in April; 8*l.* 72. *Cockerel* by Sam, hatched second week in April; 2*l.* 5*s.* 73. *Pullet* by Sam, hatched second week in April; 3*l.* 5*s.* 74. *Pullet* by Sam, hatched third week in March; *Cockerel* by Patriarch, hatched first week in April; 3*l.* 5*s.* 75. *Pullet* by Patriarch, hatched second week in April; *Pullet*, ditto; 4*l.* 10*s.* 76. *Pullet* by Sam, hatched second week in April; 3*l.* 5*s.* 77. *Pullet* by Jerry, hatched first week in April; 7*l.* 10*s.* 78. *Pullet* by Sam, hatched third week in April; 11*l.* 79. *Pullet* by Sam, hatched second week in April; 4*l.* 6*s.* 80. *Cockerel* by Patriarch, hatched second week in April; 1*l.* 16*s.* 81. *Pullet* by Patriarch, hatched second week in April; 10½ lbs.; 5*l.* 16*s.* 82. *Pullet* by Patriarch, hatched third week in April; 2*l.* 12*s.* 6*d.* 83. *Cockerel* by Patriarch, hatched first week in May; 2*l.* 7*s.* 6*d.* 84. *Cockerel* by Jerry, hatched first week in March, 9½ lbs.; 3*l.* 15*s.* 85. *Pullet* by Sam, hatched third week in April; 7*l.* 10*s.* 86. *Pullet* by Sam, hatched second week in April; 7*l.* 10*s.* 87. *Cockerel* by Sam, hatched third week in March; 5*l.* 10*s.* 88. *Pullet* by Patriarch, hatched third week in April; 5*l.* 15*s.* 89. *Pullet* by Patriarch, hatched third week in April; 2*l.* 12*s.* 6*d.* 90. *Cockerel* by Patriarch, hatched first week in May; *Pullet* by Jerry, hatched third week in April; 5*l.* 5*s.* 91. *Cockerel* by Jerry, hatched third week in May; 1*l.* 6*s.* 92. *Pullet* by Sam, hatched third week in April; 3*l.* 12*s.* 6*d.* 93. *Pullet* by Sam, hatched second week in April; 5*l.* 15*s.* 94. *Pullet* by Patriarch, hatched third week in April; 3*l.* 7*s.* 6*d.* 95. *Cockerel* by Sam, hatched second week in April; 1*l.* 7*s.* 6*d.* 96. *Cockerel* by Patriarch, hatched first week in May; 2*l.* 12*s.* 6*d.* 97. *Pullet* by Jerry, hatched third week in April; 3*l.* 98. *Pullet* by Jerry, hatched third week in April; 3*l.* 5*s.* 98. *Cockerel* by Sam, hatched third week in March; 6*l.* 100. *Cockerel* by Jerry, hatched third week in April; 3*l.* 10*s.* 101. *Cockerel* by Jerry, hatched first week in April; 12*l.* 10*s.* 102. *Pullet* by Jerry, hatched third week in April; 3*l.* 7*s.* 6*d.* 103. *Pullet* by Sam, hatched second week in April; 3*l.* 104. *Pullet* by Jerry, hatched second week in April; 2*l.* 7*s.* 6*d.* 105. *Cockerel* by Jerry, hatched second week in March; *Pullet* by Patriarch, hatched third week in April; 7*l.* 106. *Pullet* by Sam, hatched third week in April; 6*l.* 15*s.* 107. *Cockerel* by Sam, hatched second week in March;

* No one will rejoice more than *Gallus* at this refutation, for he has Shanghae fowls quite as good as any sold on the 2nd. We take this opportunity to add that some parties have, without any just grounds, thought that *Cock-a-doodly-do-o-o* intended to insinuate that *Gallus* was the party who had the eggs out of the pens at the Birmingham Show. Now we happen to know that *Gallus* was not there, and that he is a man of honour, far above such knavery. But let us also add our conviction that *Cocky-doodly-do-o-o* aimed only at the offence, without intending to point out any culprit. We should like to ask, also, of what use for sitting purposes are eggs laid in December, the month of the Birmingham Show?

We intended to have offered comments upon some of the lots, but we have only space to add, that lot 101, the seven months old cockerel that realised £12 10s., was a buff-coloured bird, very square framed, and stout, but that we think the pullets, as a whole, sold better than the cockerels. This probably arose from the fact that they had all reached the age when their greatest beauty is attained; whilst the beauty of the cockerel is not fully developed until he is about two months older.

FORSYTH MSS.

WHEN we stated that SIR JOHN SINCLAIR was the third son of his father, we omitted to observe that he was the only survivor of the three, and we deem this explanation needful, because, without it, our other statement that necessity did not stimulate him to exertion is not sufficiently apparent. The foundation of his classical attainments was laid at the High School of Edinburgh, but he subsequently received the title of LL.D. from three Universities—Edinburgh, Glasgow, and Oxford. In addition to the places in his native country which we have mentioned as returning him to Parliament, we may add Lostwithiel, and Petersfield, in England.

It deserves to be recorded as one of the bright spots in the too usually black treatment of our countrymen by Napoleon Buonaparte, that when he heard of the capture of a son of Sir John Sinclair, who was travelling in 1806 with his tutor, he immediately ordered passports to be given to them, and treated them with the greatest politeness.

One of the successful efforts of Sir J. Sinclair was the

foundation of the *Board of Agriculture*, in 1793, of which he was elected the first President. He was not so successful, however, in its management. It unfortunately acted as if it had taken for its motto "Prices, Politics, and Practice," and was dissolved somewhere about the year 1812, in consequence of the Parliamentary grant of £3000 a year being withdrawn. Its successor, "The Royal Agricultural Society," acts up to its more legitimate motto, "Practice with Science."

Whilst the Board of Agriculture existed, Sir J. Sinclair was very active in sustaining the publication of its transactions, and Mr. Forsyth contributed to them on the subjects suggested by the following letter, dated Whitehall, June 12, 1797:—

SIR JOHN SINCLAIR TO MR. FORSYTH.

You will herewith receive a copy of the plan, according to which it is proposed to have, not only the corrected Reports drawn up, but also the General Report from the Board of Agriculture, respecting the state of the kingdom at large, by which you will perceive that it is intended to have a distinct chapter on gardens and orchards.

It is extremely difficult to find persons fit for drawing up the different chapters, who unite a talent and capacity for writing with a practical knowledge of the different subjects which it is necessary to have explained, and that is particularly the case in regard to gardens, and even orchards, though we have already collected a great deal of information respecting that branch of our inquiry.

I will shortly endeavour to explain the nature of the paper that it would be desirable to have drawn up on those subjects.

Hints for chapter 9, of the General Report, on the subject of gardens and orchards.

Introduction—On the various modes of raising food for man, by cultivating the earth, and the superior quantity of food produced by gardening.

Sect. 1.—On the production of the garden, in an agricultural point of view.

- 2.—On the most productive articles to be cultivated.
- 3.—Of the best mode of cultivating them, the fittest manures, &c.
- 4.—On the best rotation of crops, so as to produce the greatest quantity of human food.
- 5.—On the value of an acre of garden land properly cultivated as food for man, and the number of persons it would maintain.
- 6.—On cultivating food for cattle, &c. (as Lucerne), in gardens, or in a similar system.
- 7.—On the quantity of land which one man can properly cultivate in a year with the spade.
- 8.—On cottage gardens, their proper size, fittest articles of produce.
- 9.—Of the fruit-garden, and the quantity of food that may be produced in fruit-gardens, per acre.
- 10.—On orchards.

Conclusion—On hot-houses.

It is certain, that fruits may be considered rather as a luxury, or, in hot seasons of the year, as a kind of medicine, and as calculated rather for producing drink than food. At the same time, it is a subject too important to be entirely omitted in an agricultural report on the general state of the kingdom and its productions. The paper need not be long, giving merely a general view of the subject, without entering too much into detail.

If you have leisure to undertake such a paper, I am persuaded that, coming from your hands, it would give great satisfaction to the Board and to the public, which I need not add, would be doing a material service to the country.

N.B.—Sir John Sinclair is particularly anxious that Mr. Forsyth should draw up such a paper for the Board, as he has such access to obtain authentic information on the subject of kitchen-gardening in particular, from the numerous body of gardeners in the neighbourhood of London.

COVENT GARDEN.

THOSE only who live, and those who have lived, in London, know the effect a wet day has on the trade of this great mart; but, when such a state of matters continues, not for one day, but for six, the effect is great indeed. Such has been the case for the last week or ten days, and the consequence is, that business of every kind has been at its lowest ebb. It would be strange if, in the midst of all this depression, Covent-Garden should escape; and still there are some who wonder why it should not, for, say they, people must have potatoes, and cabbages, and fruit; these don't spoil with a wet day, and consumers do not go to market themselves. But, when it is considered that a great amount of the market produce is supplied to costermongers, and that during such weather as we have had lately these persons cannot follow their calling in the streets, it will be at once understood how it is the market has been heavy.

FRUIT.—The supply of fruit continues abundant. In APPLES, the winter varieties begin to come up, and among them we observed our old friend the *Catshead*. This is a fine old English baking apple, not so much cultivated in these days as it once was, but still a favourite in all markets. Wherever there is an orchard planted for the supply of large towns, this is one variety which should always be introduced, as it measures well, and is always in demand. The *Yorkshire Greening* has also appeared during the week, and this, too, is one of those which meet with a ready sale; it is well adapted for sauce, and generally commands a good price. The *Hanwell Souring* is another of the same description, and of it there have been several parcels. The prices which these cooking apples make is from 3s. 6d. to 4s., and 5s. per bushel when very fine. *Golden Winter Pearmain*s still continue abundant, and realised from 3s. 6d. to 5s., according to the quality. We have also observed a few *Dumelows Seedling*, but it is rather early for them. *Ribston Pippins* are still plentiful, and make from 5s. to 7s. 6d. per bushel. *Downton Pippins* are to be met with at the same prices, but not so plentifully. We stated last week that *Newtown Pippins* had arrived from America. This, and the *Lady Apple*, is, we believe, the only apples which are imported to this country as rarities, and the reason is, because they cannot be produced in this climate in the same degree of perfection as in America. Even against a wall the fruit of the *Newtown Pippin* never possesses the same fine flavour as is to be met with in the imported specimens. The *Lady Apple* is the variety which is known in the collections of this country and the continent as *Pomme d'Api*. It was first introduced here in the reign of Charles the Second; but the only attraction it seemed to have was, that it "served the ladies, at their toilets, as a pattern to paint by!" We do not know to what use they are applied now, but we may charitably suppose that the lady who bought half-a-dozen the other day in the Covent-Garden arcade had no intention of applying them to such a purpose as the *belles* of Charles's time did. PEARS are also plentiful. *Beurré Capiaumont* continues to take the lead. A few *Bishop's Thumbs*

may still be met with, and several bushels of *Messire Jean* have also been offered. This was, at one time, grown to some considerable extent, but its cultivation has now been discontinued; and we question if there is a nursery where it is now propagated. The orchards from which the supplies have come must, therefore, be of an early date, for since the beginning of this century, at least, it has not been met with in the nurseries in any quantity. It is one of those old French varieties, which were, in all probability, introduced by London and Wise, of the Brompton Park Nursery. We observed also, in the centre arcade, a few *Glout Morceau* and *Passe Colmar*; of these we shall remark on a future occasion. They are both first-rate varieties, and should be in all choice collections.

VEGETABLES.—There is no variation either in the supply or the prices of vegetables. *Cabbages* are plentiful, at from 6d. to 1s. 6d. per dozen bunches. *Cauliflowers* are also plentiful, at 2s. 6d.; and, indeed, every other description of this department continues much the same as last week. We need not, therefore, repeat what we said in our former reports.

PLANTS AND FLOWERS.—The supply of EVERGREENS IN POTS continues to increase. They are generally handsome, well-grown, bushy plants, and consist of *Aucuba japonica*, *Red Cedars*, *Siberian* and *Chinese Arbor vite*, *Tree Box*, *Spruce Firs*, and *Laurustinus*. CUT FLOWERS are becoming more choice, the recent cold, wet weather having played sad havoc among the border flowers. They consist chiefly of *Camellias*, *Scarlet Geraniums*, Double and large-fringed Single *Chinese Primroses*, *Verbenas*, Double *Blue Violets*, and *Azalea Indica*. Some of the BOUQUETS are very beautiful. We promised last week we should, from time to time, furnish descriptions of any which attracted our notice. We noticed one this week which had a fine, large, double white *Camellia* for a centre, round which was a thick belt of double blue *Violets*; these, again, were bounded with another belt of *Scarlet Geraniums*, and the whole fringed round with leaves of the *Rose-scented Geranium*.

H.

GOSSIP.

HE who has written one of the best books upon *British Ferns*, Mr. Moore, Curator of the Chelsea Botanic Garden, is the most fit person to prepare other assistance for those whom he has induced and aided by his little volume to collect specimens of this beautiful order of plants. One of the first wants felt by such collectors is that of a neat and correct set of *labels* for his collection. To supply this want, Mr. Moore has published a complete set of *Fern labels*. The names of the *sections* of the Order are in large capitals; the names of the *genera* in smaller capitals; and the names of the *species* in letters still smaller, but all very legible. The names of the botanists who bestowed each title, and some synonyms are added to the specific names.

The following is an epitome of the results of the cultivation of *Kitchen Vegetables* and *Fruits*, alleged to

be new and superior, that have been published in the "Journal of the London Horticultural Society." The experiments were conducted, and are reported, by Mr. R. Thompson.

Hardy's Shallot Onion.—Strong flavoured; probably good keeper; irregular in size and form; "by a judicious selection of bulbs for seed, a useful sound-keeping variety may very probably be obtained."

Florentiner Pfluckerbse Pea, from Germany, proved to be our *Early Frame*.

Paradise Pea.—Sown May 17th, fit for use July 23rd; four feet high; good quality; abundant bearer; allied to the *Early Charlton*.

Doré de Fitz-James Pea.—Sown May 17th, fit for use July 20th; four feet high; very good, but a curious degeneration, probably, from the Charlton, the pods and peas being yellow.

Sutton's Early Goliath Pea.—Sown May 17th, fit for use July 18th; four feet high; "a very good, early, productive pea."

Sutton's Superb Marrowfat.—Same as Woodford Green Marrow.

Early Prince of Wales Pea.—Sown February 16th, fit for use June 25th. "A well-selected *Early Frame*."

Royal Alfred Pea.—Sown February 16th, fit for use July 14th; three to four feet high; large and good; "a sort of Marrow, but not so sugary as Knight's."

Trial of Early Peas.—The following are the results of sowing of different kinds of Early Peas, made with the view of ascertaining their comparative merits in point of earliness:—

1. <i>Early Frame</i>	.	sown	November 15;	fit	June 4.
2. <i>Early Kent</i>	.	do.	do.	15;	do. 4.
3. <i>Early Emperor</i>	.	do.	do.	15;	do. 4.
4. <i>Sangster's No. 1</i>	.	do.	do.	15;	do. 4.
5. <i>Early Charlton</i>	.	do.	do.	15;	do. 24.
6. <i>Early Long-podded</i>	}	do.	do.	15;	do. 24.
<i>Bishop's Dwarf</i>		do.	do.	15;	do. 24.
7. <i>Early Surprise</i>	.	do.	do.	15;	do. 24.

The first four of the above may be considered identical. Sangster's No. 1 was admitted to have been sent out in mistake. Slight differences will take place in the *Early Frame*, and other sorts, in consequence of the mode of sowing. Hence the *Early Kent* and *Early Emperor*; but they are certainly not decidedly different permanently. They were exactly alike in the above trial.

Haricot de Prague jaspé.—A tall running Kidney Bean; not good in its green state; dried seeds said to be excellent.

Haricot de Belgic.—A running Kidney Bean; pods five inches long, and still tender; tolerable bearer, but not very early; very good, but must have support.

Bush Haricot (Haricot solitaire).—Fifteen inches high, and branchy close to the ground like a bush; pods abundant, five inches long, crisp, transparent, and excellent; commence forming early, and continue long in bearing; dry seeds, speckled red and white; must be grown two feet apart each way. "Forms a valuable succession to the earlier sorts, especially during hot dry weather."

Small White-seeded Haricot.—A variety of the *Haricot viz.*, but earlier, more productive and hardier, "Not so good as various others."

Newington Wonder French Bean.—Excellent; one foot high; early and productive; pods very fleshy, and seeds form slowly; grown in rows eighteen inches apart.

Black Belgian Kidney Bean.—Best both for early and late sowing. Dwarf; sown in pots and planted out when earth warm enough; and late in summer will produce a crop until cut down by frost. "This and the *Newington Wonder* are considered the best varieties of Dwarf Kidney Beans."

Türkische Bohne.—This Kidney Bean is the same as the *Sabre*.

Duchesse de Trévise Strawberry.—Presented to the Society by M. Jamin, Bourg-la-Reine, near Paris, September 6, 1851.—Fruit middle-sized, ovate, deep red; seeds small, rather deeply embedded; flesh pale red, juicy, with a brisk rich flavour. Leaves large, roundish, widely and rather obtusely serrated. Leaf-stalks moderately tall, very hairy, the hairs on these spreading horizontally, but those on the scapes and runners are adpressed. Appears to be a good

bearer, ripening quite as early as Keens' Seedling. It will require to be planted as widely apart as the sort just mentioned. As far as can be judged of it in the present season it seems deserving of cultivation, or, at all events, certainly of further trial.

Salter's Versailles Strawberry.—Presented to the Society by Mr. John Salter, Nurseryman, Hammersmith, Oct. 24, 1852.—Fruit large ovate, sometimes flattened or cockscomb-shaped; dark red; seeds rather deeply embedded; flesh pale, juicy and rich. Leaves middle-sized, roundish-oval, widely serrated. Leaf-stalks, scapes and runners hairy, the hairs spreading almost horizontally. A good bearer, ripening about the same time as Keens' Seedling, to which it will doubtless be preferred by those who like a brisker flavour than is possessed by Keens' Seedling. On the whole, it is worthy of recommendation, being large and a good bearer; many of the new sorts have these properties only, but this has also good flavour.

Beadnell's Seedling Pear.—This was raised by John Beadnell, Esq., West Green Road, Tottenham, and cuttings of it were presented by him to the Society.—The fruit is nearly middle-sized, turbinate, stalk short; eye a little open; skin pale yellowish-green on the shaded side, red next the sun, much speckled with whitish-grey dots. Flesh melting, exceedingly juicy, and rich. It is not buttery, but so melting, when used in its full perfection, that one can scarcely say whether he is not rather drinking than eating. Its period of ripening varies between the middle of September and that of October. It does not keep long after being ripe. The tree is vigorous, and bears very abundantly. Shoots long, bright chesnut coloured where well exposed, much spotted with whitish spots. Leaves moderately large, cordate on the young shoots, somewhat concave and acuminate, serrated; those on the spurs are elliptic. Stipules linear, rather more than half the length of the petioles. This variety cannot fail to be very acceptable on account of its rich, abundant, and highly refreshing juice.

Shanghai Peach.—This variety was sent to the Society Mr. Fortune, who found it growing to a very large size in the North of China.—Along with a plant of it in a pot, he sent some of the peach stones. These were sown and came up abundantly; but they had a very unpromising appearance for fruit, their foliage being narrow, and altogether unlike that of a cultivated sort. They were, however, potted, and when fit, used as stocks for the original. Several trees on these stocks were planted against a south wall, where they grew rapidly. The trees have produced better fruit this year than formerly, probably owing to unusually high temperature in July. The flowers are large; the leaves of the petals deeply coloured. Leaves crenated, with reniform glands. Fruit very large, ten inches or more in circumference, roundish, and very handsome; pale yellow where shaded, and delicate crimson red next the sun. The flesh is pale yellow next the skin, but very deep red at the stone, to which it is attached by strong fibres, yet it is not everywhere adherent like the flesh of the cling-stone peaches. It is juicy and rich, but it requires to be gathered a day or two before it is used. In this state some gentlemen preferred it to old esteemed sorts. It ripens about the same time as the *Bellegarde*. The tree is a good bearer. Buds of this sort have been distributed to the various nursery-men or other Fellows of the Society who applied for them. It must, however, be observed, that it requires a good aspect, and warm situation. It would probably answer for forcing, with plenty of heat. Some buds of it were sent to Paris, and there its fruit is said to be splendid. Like all large fruited varieties it ought to be well thinned."

The following is a list of the *Horticultural and Poultry Shows* of which we are at present aware. We shall be obliged by any of our readers sending us additions to the list, and giving the address of the Secretaries.

HORTICULTURAL SHOWS.

BURY ST. EDMUNDS, NOV. 26 (Chrysanthemums). (Sec. G. P. Clay, Esq.)

CALEDONIAN (Inverleith Row), Edinburgh, Dec. 2.
 HAMPSHIRE, Nov. 18 (Winchester). (Sec. Rev. F. Wickham, Winchester.)
 LONDON FLORICULTURAL (Exeter Hall, Strand), Nov. 23, Dec. 14+.
 NORTH LONDON, Nov. 23, Chrysanthemum.
 SOUTH LONDON (ROYAL), Nov. 11+, Dec. 9+, 16.

POULTRY SHOWS.

BIRMINGHAM AND MIDLAND COUNTIES, 14th, 15th, 16th, and 17th December.
 BRISTOL AGRICULTURAL, December 7th, 8th, and 9th. (Sec. James Marmont.)
 CORNWALL (PENZANCE), January 10th, and 11th. (Secs. Rev. W. W. Wingfield, Gulval Vicarage, and E. H. Rodd, Esq.)
 DORCHESTER, Nov. 18th. (Sec. G. J. Andrews, Esq., Dorchester.)
 HONITON, January 12th. (Sec. H. K. Venn.)
 WINCHESTER, December 1st. (Secs. G. W. Johnson and J. Colson.)

† For seedlings only.

PREPARATIONS FOR EARLY FORCING.

THE shortest day is not far distant, and the adding one more year to the world's history is the signal with many to prepare for garden luxuries during the ensuing spring. Hundreds, however, are not thus patient, but require things much earlier still—and to such the shortest day forms no rule. To obtain Strawberries in March, Grapes and Figs in April, and Peaches in May, requires that the early forcer put his house in order immediately.

First, then, the *Early Vinery*. What must be done—and in what order? If the roots are inside the house, little will be required. If the Vines have been done justice to at the close of their former labours, their roots will have become somewhat dry—a very wholesome condition to remain in during the rest period. In consequence, the border will have become husky on the surface, and, as much of this as has lost its texture, may be removed, and a little fresh compost, if necessary, be substituted; but it will be well to ease the whole over with three inches of half-rotten manure—that from old hotbeds, where half the volume has been tree leaves is excellent. And now, the border being dryish, let us advise a liberal watering with tepid liquid-manure; but, as it is not proper to risk any lodgment of this powerful fertilizer, it may be applied, in a moderate quantity, three days successively, and will thus quietly penetrate the mass. Of course, the Vines for such early forcing have been pruned, and the wood dressed; if not, we pity the forcer, if the Vines have been forced early in former years. The dressing should be applied at twice, but, before doing so, every portion of loose outer bark must be peeled off, for there is no safety if any be left on. Then let the dressing be applied, and a good practice is, to add plenty of lime to the first coat: this, when dry, will prove a tell-tale, and show the operator, at the second dressing, any portion which may have been missed. If the roots of the Vines are partially or wholly *outside*, the first thing should be the covering of the border with litter, in order to at least exclude frost; and if the material be in a fermenting state, all the better. We think that a temperature of 60° to 70° will be amply sufficient until the buds swell, when it may be increased 5°. And here we would recommend the use of a good tarpaulin to cover the litter, in order to keep out rain and snow: perhaps this article will be as good and economical a thing as can be devised. It is quite obvious, that borders which have been exposed to all the autumnal rains contain sufficient moisture to last them until the new year, at least. If any loose material, the remains of former top dressings, remain on

the surface of the border before covering, we would rake it clear off—or, at least, as far as surface fibres would permit, so as to enable the fermenting warmth to penetrate the border. When the warmth of the fermenting material needs increase, it will be well to introduce muck of the droppings from the stable door, in order to impart richness to the border, when rains or waterings are permitted. Thus far the roots; now for the structure itself. Again we may point to the thorough cleansing requisite in all forcing houses before commencement. This, of course, will consist in washing down, or painting, all wood-work, using strong lime-washes to walls or brick-work, and in washing the roof and other lights as clean in the glass as a drinking vessel. All this complete, let us again advise, in all cases, a good stoving with sulphur, continued for several hours—say from daylight to dusk; and if the operator can cover his roof with mats, canvass, or anything, all the better: closing the frames in as much as possible.

It will be here observed, that nothing with foliage on can remain in during this process. The operator will find this a good chance for stoving his Figs, Vines, Peaches, Cherries, &c., in pots or tubs, for they might be removed here previous to the operation. And now let us inquire if the flues have been thoroughly cleaned; if not, it must be done immediately, and hot-water machinery examined and reported on; for a break-down in midwinter will not obtain the gold medals of Regent-street.

All these things duly carried out, the first steps of forcing may be taken, such consisting, in a great degree, in a reversal of the rest policy. A dry atmosphere must gradually be exchanged for a moist one, and the temperature may be allowed a slight advance. In all these things let nature be imitated; generally speaking, what is termed a mild and soft March day may be the model. Thus, suppose a vinery closed in the last week of October, the temperature might run about thus—

First two weeks in November	about	50°
Third week	ditto	55°
Fourth week	ditto	60°
First fortnight in December		65°
Last ditto	ditto	70°

However, these things depend on other circumstances as well; for as soon as the buds are expanding, the night and day thermometer must differ considerably, for thus nature manages her affairs. If the buds are found to break shyly, or irregularly, more time must be given, or the trees will produce an unsightly crop. The syringe may be plied night and morning, using a fine rose, in order not to batter the dressing-off; and sprinkling must be a constant practice, morning and evening, on the floors, walls, &c. If the operator can introduce fermenting materials, it will be of great service to the Vines; such, turned and sprinkled twice a-week, will produce a most genial kind of humidity in the air of the house. Ventilation during the first month will be resorted to, simply to get rid of surplus heat; and thus matters may proceed until the Vines are in leaf. Having other matters pressing for some future papers, we must here just take a passing glance at other candidates for precocity, and, first,

PEACH-FORCING. Here the same preliminaries are requisite as in the vinery; thorough cleanliness, the use of lime, &c. And here may be named the propriety of adding much sulphur to the lime, which, indeed, should be constantly done in all plant structures; the benefits are more considerable than people commonly imagine. The same wash will answer here as with the vines: this having been so often described in these pages, it may suffice to observe, that it is composed of a clay paint, to which much sulphur and lime are added; and soap liquid added at the rate of four ounces of soft soap to a gallon of water. Every crevice in the branches must

be searched with this dressing; and it should be repeated at an interval of a couple of days or so. In addition to all this, the stoving suggested for the vine will so purify the walls, shoots, &c., that it is probable not even the eggs of the insects will escape. It was the neglect of such extreme precautions in former days which caused such a hubbub about red spider, &c. In those times it was counted nothing extraordinary to see houses under good gardeners of the day overrun with this terrible pest; but now, woe to the credit of a man of any standing in his profession who looks coolly on whilst these insect tribes are committing their devastations.

It happens very fortunately that sulphur, which is antagonistic to the red spider, is so likewise to that terrible scourge of the vine, the *Oidium Tuckerii*, or vine mildew: this is, indeed, a fortunate thing. If the Peaches have not been pruned it must be done instantly if for early forcing, of course before dressing, and great care must be taken in this operation. We may here take occasion to dissipate a serious error, a gardening mesmerism, which is totally unworthy of the day we live in; and that is, the impression that every shoot of the Peach *must* be shortened back. This is consummate nonsense; and the error has arisen from the want of a due consideration of the different degrees of ripeness attained by in-doors and out-doors Peaches as we commonly find them. With regard to the latter, it is very generally necessary to shorten them on account of the immaturity of their points; but with the house Peaches the same reason is not, or ought not, to be present; and the chief reason for shortening in-doors, consists in its tendency to keep the lower portions of the tree well furnished.

Peaches and Nectarines, of some age, and which have been tolerably hard-worked, are very apt to be minus wood buds except at the terminal point. We have frequently seen shoots, which were studded with blossom buds from the base to the extremity, preserving but one wood bud at the very point. Now, it is obvious to any one, that to prune this shoot at any point is to destroy it; and this is not all. Trees of this character rejoice in having their leading buds unmolested: they sustain more lively action in the tree than mere secondary shoots; trees of this habit being below the medium point of luxuriance, and requiring in general some stimulus to keep them going. Let, therefore, common sense prevail in this matter; do not shorten any shoot of a doubtful character; rather leave it to nature. The best wood of all is that which is studded with triple buds, from the base to within a few inches of the apex. These triple buds are almost invariably a wood bud in the centre, and a blossom bud on each side; and are indicative of that happy medium of strength which at once points to well-balanced habit and to a high degree of fruitfulness.

Vines and Peaches, in pots or tubs, must undergo a similar ordeal to those planted out, before forcing; and greater caution still must be exercised over the pruning of pot Peaches. If fermenting materials are at work in the houses, we would make up one portion milder in character, by introducing a good body of tree leaves amongst the warm material, and securing a steady bottom-heat of about 60° to 65°; in such the Vines, Peaches, Figs, &c., in pots or tubs, might be plunged for awhile.

STRAWBERRIES.—Although some persons must needs introduce these in November, or even earlier, in order to have them ripe by the end of February, or beginning of March, yet not one of these ever dreams of success, that is to say, of Strawberries not only red, but actually fit to eat. However, we will not step out of our way to check the progress of science and the refinements of luxury, inasmuch as such recreations have, at least, a wholesome tendency. For, although the gar-

dener may be occasionally troubled with the nightmare whilst his Strawberry blossoms are setting, or, rather, making an effort to do so, his conscience may all the time have a mere sinecure office of it. Nevertheless, it is a pretty-well recognized fact, that few gardeners attach any mighty importance to Strawberries introduced whilst the days are shortening. To those who choose to do so, we beg to suggest the use of a frame or pit for awhile; not that there is any magic about such structures, but that in them the two great desiderata as to Strawberry commencement are most generally to be met with, viz., proximity to the glass, and a little warmth without the smell of fire, and, in addition, those genial gaseous emanations which mere fire and water can never supply equally to sweet fermenting materials. In such a structure, plunged in a body of fermenting materials, which is merely suspected of containing a little warmth—say 60°—the Strawberry plants may take first lessons in the art of forcing. Here, with an atmospheric temperature of 50° to 55°, they may remain three weeks, or, indeed, until the blossom-bud first becomes manifest, when they will do with more warmth, always keeping them near the light and ventilating points. Like Dutch bulbs, however, about which our good friend Fish could tell a pretty tale, it is of no use talking of schemes and appliances if the bud has not been well organized in the preceding summer. As our sage ancestors used to say to hot-headed young folks who were o'er hasty to get married, "as you make your bed so you must lie," so may be said of the Strawberries; if the bed is not well-formed, it matters not whether pit or house.

In putting by our "Gillott" for a few days, we may just observe, that all forcing stores, such as Vines, Peaches, Apricots, Figs, Cherries, Strawberries, &c., whether in pots or tubs, must have protection immediately at their roots, if not hitherto afforded them. Plunged above the ground level, on dry ground, and their branches covered in very severe weather with a little clean straw, they will be in a position to introduce to a forcing process at any time. Trees in pots, thus situated, cannot afford to lose what few roots they possess; and, it must be remembered, that in pots above the ground level they are in a most defenceless state: they love not the every-day fluctuations of a changeable November and December.

R. ERRINGTON.

SCARLET GERANIUMS.

SOME time since, I made a promise to our correspondent, "Devonian," that I would find out for him all that was necessary to know about the new Scarlet Geranium, *The Amazon*, of which he himself spoke highly. He wanted a good selection of them for planting against a high wall, where they live out the winter with him in Devonshire, with a slight protection. When I was at Clapton, the other day, about the packing for long voyages, the first plant I inquired about was *The Amazon*, and I find it is a horse-shoe variety, and the very best of all scarlets, for a wall, or for the centre of a very large bed of them, or for making specimen plants ten or twelve feet high, as Mr. Macintosh has them at the Duke of Buccleuch's gardens at Dalkeith, near Edinburgh. If "Devonian's" border is good, *The Amazon* will reach the top of his wall in four years, or five at the farthest. All this I can vouch for, from my own experience, for I have grown *The Amazon* for eight years, and I have described it in THE COTTAGE GARDENER long since. Mr. Cole, now gardener at Oldford, near Birmingham, was the first man in England who saw this Geranium. In 1843, he pointed it out to me among a lot of seedlings, from the *Shrubland Scarlet* alias *Smith's Emperor*. From that day to this it has

been my own peculiar favourite of all the Scarlet Geraniums, so much so, that no one ever had a cutting of it. All this I told Mr. Low, and pointed out the variety to him, out of many hundreds of plants he had in a long range of pots, before he told me which was *The Amazon*. It has the largest flower-truss of all the race, and if I had anything to do with the Gardens at the New Crystal Palace, I would buy up every plant Mr. Low could spare of it, in addition to the 50,000 scarlets already bespoke for that establishment. I would plant it in masses, in the centres of the largest beds, placing broad bands of *Punch* next to it, and a double row of *Tom Thumb* next the outside. For a match, and as a contrast to this, I would plant equal numbers of the oldest and strongest *Salmon Geranium* I could find, then the *Pink Nosegay* to balance *Punch*, finishing with *Lady Middleton* on the outside. I would either so arrange them, or I would put the scarlets in pairs or match beds, and the shaded pinks the same. This last would be the most complete arrangement, but either way would be more grand and imposing than any other that all the gardeners in England could make out of all the scarlet breed put together. If *Cherry Cheek* could be depended on, it would be better than the *Nosegay* to make the shading more perfect. It would be dangerous, however, to trust to it, where all the beds will be made with fresh soil, and where we all expect to find flower-gardening, like the rest of the designs, in the highest style of art. Meantime, Mr. Low's plants of *The Amazon* are from a foot to thirty inches high, and the price is about 3s. 6d. a plant. Next April we shall have it for 1s. or 1s. 6d., but then it will hardly be so cheap as it is now, because the plants will not be nearly so large and strong.

Here I met with a good stock of the *Shrubland Pet*, the very opposite to *The Amazon*, being the smallest flower of its class, and, like *The Amazon*, it has been raised by more than one grower. I traced it to two different hands this summer; and Mr. Ayres told me of three others who lay claim to its origin, and very likely they are all right; but what is better for our present purpose, I found, down near Oxford, an entire new bedding Geranium, that is, new to me and THE COTTAGE GARDENER. I only made mention of it once, and that as a desirable one to cross from, if it was a breeder, which I now find it is not. We must have a bed of it to match *Lady Mary Fox*, if the London trade can supply so many of it. It is the only one in existence that will match *Lady Mary Fox* exactly, and it is just as good as her ladyship, which we all know is the best of that race. The name is *Touchstone*, and, like *Lady Mary Fox*, it should never be propagated, except early in the spring, and old plants of it should be cut down quite close to the hard wood every autumn, when the plants are taken up for the winter. Forcing either of them in the spring is much against them, but when the old plants are cut and potted in the autumn, a slight bottom-heat in an airy pit for five or six weeks would do them real good; and the next best place for them would be high on a shelf near the glass, in a dry stove, as all stoves ought to be from the middle of October to the end of November, the time when this assistance would be so beneficial to *Touchstone*, *Lady Mary Fox*, and the *Golden Chain*, and also to all other Geraniums under similar circumstances, if we could but afford space for them.

For my knowledge of *Touchstone*, as a first-rate bedder, I am indebted to the Rev. J. Lys Chilworth, Wheatley, near Oxford, whose garden was as clean as a drawing-room, and as tastefully planted as any I have seen since I left Suffolk. His beds are also as full of bloom as we ever had them at this time (Oct. 10th) at Shrubland Park. *Touchstone* here being as good as ever I saw *Lady Mary Fox* in August; and I was told

that "you could not see a leaf in it" earlier in the season, for the mass of crimson flowers.

Ethiopia prostrata was here all bloom: the only place where I have seen it this season. The secret of its doing so well is, that old plants only were used, and divided late in the spring, allowing them room enough to spread well before they were too crowded. *Linum flavum* makes a hardy bedder here, and is never taken up; it was then in bloom. *Unique* was very fine, and so was *Calceolaria Kayii*, and another dwarf yellow *Calceolaria* called *Compactum*, which is very common about Oxford. The old *White China Rose*, which I have so often mentioned, will be in bloom here to Christmas if we do not have much frost. There are several beds of this Rose at Kew this season, where it is tallied *Rosa alba*, proving what I have always said of it—that it was fortunate enough to get about before they began to name the sorts from the breed of the old *odorata*. There was a large plant of *Helenberg* Rose against the house in fine bloom: this is a climber of the Noisette family, and, as it would seem from this example, among the best of them; the flowers are—or were this time—of a deep crimson colour, with the foliage and growth looking very healthy. A fine plant of *Chionanthus fragrans*, or *Grandiflora*, ripened seeds the same as at Claremont (p. 60). The seeds vegetate freely, and it is a thousand pities that a seed of this kind should be lost anywhere until the plants can be sold for five or six shillings the dozen. I saw many plants here that are very scarce round London. Among them are some of the best *Cistus*, or Rock Rose, *Bomarea*, a section of the *Alstromerias*, *Pentstemons* and herbaceous plants. In the greenhouse, *Gesnera zebrina* was in full bloom, just a month earlier than most gardeners in large places, who aim at large specimens, can bring it into the rooms or conservatory. I saw it also in bloom in a conservatory at the end of last August, in the next parish to me, and the mode of culture I found to be exactly the same in both places; and, as October is the worst month in the year for keeping a greenhouse, or any house gay with flowers, I would recommend the same plan to be adopted with part of the stock wherever this *Gesnera zebrina* is grown, or, indeed, wherever a cucumber bed is made in March. Early in March they pot, in the same pot in which they flower, large tubers whole; three tubers in a No. 32-pot. From 75° to 90° is the general heat for the bed at that time, and the pots are kept in such heat to the middle or end of May, when they are removed to adorn the greenhouse, and help to fill it along with other nice things after the "greenhouse plants" are turned out for the season. The *Gesnera zebrina* is so soft and fleshy in all its parts, that this violent change does not show any bad effects, but the shock puts a dead stop to the rapid growth of the plant for a while—a sudden check, as we gardeners say. A disposition to flower is then induced, and when the plant moves on again, a flower spike appears, which takes a long time to come to perfection under a greenhouse treatment, but still they do come to perfection a month or two sooner than by stove and shift culture, although the plants be only a quarter of the usual size. I think the following application of this principle would succeed; and if it would, I know many a good gardener who would reap the benefit of it. Take single, whole tubers, and pot them in No. 60, or three-inch pots, placing the bottom of the tuber on the drainage crock, and filling up, quite firm, with half peat and half leaf-mould compost; any time in February or early in March, plunge them into a brisk bottom-heat of 80° to 85°, and a damp, growing atmosphere. After the first watering, no more will be needed till you see the leaves appear; then keep them constantly moist at the roots and over head, and get as much growth out of them as your means can furnish before the end of May; then turn them into a cold pit, with a very dry

atmosphere, and keep the sun from them till they harden a little. It is now Midsummer, and time for them to be in an airy and light part of a greenhouse, or late vinery; and to guard against the scorching of the roots in these little pots, have all double potted, that is, to put the No. 60-pots inside 48-pots. Before the middle of July the flower-spikes ought to appear; at any rate, keep them on short commons till they do "show;" then sort them into fives, keeping each five, as near as possible, of the same forwardness; water them all thoroughly, and put each five into a No. 16-pot, one in the middle, the rest equally apart near the sides. No matter how rich the compost is for this move so that it is light and lumpy, to let off the large doses of very weak liquid-manure, with which the future waterings are to be made, until the first flowers open; and during this interval, let them be in a close, strong-growing heat, so as to expand all their parts, as much as possible, before they are fit for showing off. After all, this is only a new application of a very old rule by which little Coxcombs not much bigger than your thumb at the time of "showing" the flower, or crest-bud, have been made to expand enormously—and why not *Gesnera zebrina*? Even with a moderate growth, five of them in a pot will make a handsome specimen; the flowers will be just as numerous, and the flower-spike nearly as long as if the plants were grown to their last in single pots, besides being six weeks earlier. The other half of the stock of roots will be used to make the splendid specimens now so much admired.

D. BEATON.

TENDER PLANTS THAT MAY BE KEPT DORMANT IN WINTER.

A PHILOSOPHIC moralist would be apt to say, that modern *upwardism* was one of the plague spots of society. True, we may realise the blessing of contentment, and not be backward in using legitimate means for improving our condition. Ambition only becomes an evil, when, in aspirations after the future and the unattainable, we forget our present advantages and their attendant responsibilities. How many destroy their happiness, keep themselves in a perpetual worry, and render themselves incapable of all useful, generous effort, merely because they *will* aspire to dangle within the extreme bounds of a higher grade, when they might otherwise have been happy, prosperous, and useful, as standing in the foremost ranks of the hardy sons of honourable labour. "Then why is it that you, in your COTTAGE GARDENER, talk so frequently of plants which none but the rich can possess and attain; conjuring up envy in some, discontent in others, an aping refinement in more, and a straining to have plants like their *bettors* in all?" Just because, I believe that *envy* belongs to *no* particular condition in life, and can only be associated with the *diminutive* in mind; because, I believe that a man may have something of philosophy in his head, and a great deal of the real gentleman in his manners, and be all the happier, and more faithful to his duties in consequence; because, I know that the sight of, and the acquaintance with, without the possession of, the beauties of vegetable nature, ever exert a cheering, humanising, bettering-of-heart tendency; and because I am more than convinced, that the love of gardening, however promoted, and however directed, is a most powerful auxiliary for securing happy homes, and promoting self-respect, and manly independence of feeling. "Aye, that is it, they get so *uppish*, and so independent; since they have had these fine cottages, large gardens, and allotments, they think nothing of *charity now*." So spake, not long ago, a querulous old gentleman. I hope it is true. Charity, rightly administered, is one of those virtues that breathes peculiarly of

the atmosphere of heaven. But I trust that the day is dawning, when an addition to the reward of labour shall be no longer given in the name of charity, as an opiate to the conscience, which *ought* to have been given at once as a matter of simple *justice*. Self-respect can stoop to charity *only* as the last alternative. Gardening fosters that self-respect, because, in the country especially, it is a safeguard against vice and idleness. Mind *will* think, and the good must be presented as the opponent of the bad. Glad are we to know, that there are those high in rank who glance over these pages. Pleased are we to see THE COTTAGE GARDENER on the tables of gardeners, of Dukes and Earls; but more delighted, more satisfied would our ambition be, to know that this little manual circulated *more* among the tradesmen, artisans, and labourers of our land. Some, in their enthusiasm, might spend more on plants than their circumstances would justify, and thus develop *upwardism*. In all cases not very extreme, I am so convinced of the good that would follow, that I should be inclined to shut one eye at least. To suit a few with aspirations above their general conveniences, I will pen a few notes on the subject that heads this chapter, even though they be chiefly remembrances.

I. *Scarlet Geraniums*.—These have been discussed under almost every conceivable circumstance. Still, I must not pass them by, as they generally constitute the first step from the democratic to the aristocratic in gardening. 1st. There are those that have been growing and blooming in pots and boxes. If you have not given them much water lately, they will be rather firm in their stems; and kept so dry as that they do not shrivel, they will be preserved easily in any hay-loft or shed, where just a little light can be given in fine weather. All fading leaves should be removed, and the points of the shoots, if at all succulent. In March and April, you must bring them more to the light, and moisten their stems in a sunny day. By-and-by, when the weather becomes warmer, you must water them at the roots; and, if set out-of-doors, you must protect from wet and frost; and when the plants have broke nicely, you may pick off some of the old soil, and top-dress with what is fresh and rich. You will thus have abundance of bloom. 2nd. But you wish to preserve those growing in beds and baskets; and as the roots have been cut in autumn, you would like to keep the plants green all the winter, after taking up and potting them. Then, though the plants may be somewhat dormant, you will be obliged to give them a fair portion of light, as well as keep them from frost. Any building, or an odd room where these conditions are obtainable, will do. 3rd. "Here are a lot more that are still in the ground, and have received no preparatory process, and I have nothing but a close shed, with a window and largish door to preserve them, or a small bed covered with lights, and I should like them to do well next year. Will either place do?" Take up the plants carefully from the beds, and, as your room is scarce, cut away all the softest part of the plant, and the whole, or, at least, all the larger leaves. Then have a pot of quick-lime, if there is some powdered charcoal in it, all the better; dip the top of the plant in it so as to smear all the cut parts; and then pack the roots as closely as you can in dryish earth, leaving the tops exposed. You may place them in moveable boxes if you like. I make many out of any old boards, but if, in your pit or shed, there is no danger of damp from below, they will do as well, and occasion less trouble by being packed on the floor. Light and air must be given them at all suitable opportunities. If they see neither for a week or more, in severe weather, they will take no harm. Frost must be excluded, and any decaying part must be removed. By the end of March they will have become such a thicket, that you must move them to give them room, to en-

courage the growing and then the hardening process. 4th. "I have no plants, but Neighbour *Lose-nothing* has offered me plenty of cuttings. I have a nice, open, light lumber-room, from which frost can easily be excluded." Well, "better late than never," though it is never good to be late. Get some shallow boxes, say three to four inches deep, six to twelve inches wide, and from two to three feet in length; put a little rough stuff in their bottom, and then fill rather firmly with dryish sandy earth. Make the cuttings rather large, leave only a leaf or two at their points, let the base dry for a day or two, and then insert them firmly and thickly in the dryish soil. Now, here is the *particular* part; in a sunny day you may dew the foliage with water, but *not a drop* must go into the soil *until* roots are freely forming. In all these cases the succulent juice stored up in the plant and cutting is that upon which you must depend. Every position indicated is, therefore, better than your own sitting-room would be, whatever bustling care you might give them, just because your fires would dry the atmosphere, and rob the plants, &c., of their self-contained moisture.

II. *Fuchsias*.—These, if not the first, are second favourites with all our artisans of taste. Nothing beats them for windows, baskets, and small gardens. As successions are easily obtained, the plants should *never* remain in-doors whenever some of the leaves begin to fade. Ripening of their wood in the open air, and a good rest, are essential to their future success. A shed or room, where they can be protected from frost, will suit them better than a window or greenhouse. If the pots are plunged, or covered over with a damp material, such as moss, the plants will want no water until fresh growth commences in spring. The damper the plants, the more liable to injury from cold. A lady, very fond of these and other plants, kept them nicely in a light lumber-room in the garden. Her good husband, though equally fond of flowers, knew nothing of their management, and wisely never interfered. One day, however, he took pity on the woe-begone aspect of the plants: he would give them a *refresher*; and tops and bottoms got the water until the place was sailing. He intended to surprise his lady on the following day, and he did. To give them every chance, he left the window open, and forgot to shut it. That night a severe frost left wreck and desolation. His mistaken kindness did the mischief. A little dry hay is useful for throwing over the tops in severe weather.

III. *Begonia Evansiana*.—This is a great favourite with our window gardeners, and deservedly so. I have already written its praises in these pages. I had pots this summer, with four and five stems in each, that were so truly fine, that some of our acute nurserymen did not know what it was. Whenever the flowers drop, and the leaves begin to fade, the plants should be set out-of-doors, where they can have plenty of sun and little water. By this time, the stems will have fallen off, or may be broken off close to the surface of the pot—and the pots themselves be stowed away in any dry cellar, room, or shed, and will take no harm in the dark, until the young shoots have risen a couple of inches in the spring. Then they should have light, and shortly have the roots divided, so as to have one, or several, shoots to a pot. If a little more heat than can be commanded in a greenhouse window can be given, such as the corner of a moderate hotbed, for a month, the plants will thank you for it in future.

IV. *Canna*.—Many of the *Canna Indica* shoots may be preserved in a manner similar to the last, provided dryness is attended to. When raising from seed a hotbed must be secured. Most of them have rhizome roots, or underground stems, resembling the common ginger. Most of them would be too large for windows, but they would look very striking in the centre of baskets and vases. I

have saved the roots of *Indica* in this manner; and also *G. gigantea*, a denizen of the south of Europe. I have heard of others, such as *aurantiaca*, *coccinea*, *lanceolata*, and *patens*, &c., being so created. But to do them well, and get them forward, all would require a help from a hotbed for six weeks or more in the spring.

V. *Tall growing herbaceous Lobelias*.—Our good friend, Mr. Appleby, has alluded to these lately, and you cannot do better than follow his directions. *Cardinalis, fulgens ignea* and *splendens*, are fine scarlets; *Pyramidalis* and *Syphilitica* are fair blues, all of which may be easily kept. All of them, treated generously with rich compost, and plenty of water, do well, either in pots or beds, if they get the help of a little extra heat in spring. At this season, I used to cut over the stems and take up the roots, in balls, and pack them in earth in a potting shed, or such place, where frost could be kept from them. I have also built them one above another like bricks against a wall, never disturbing them until the heat of spring caused the suckers or young plants to move, when they were taken out, divided, and potted. Two or three old plants *now*, will give you a hundred then.

VI. *Salvia fulgens, patens, coccinea, Chamædrifolia*, &c., may be taken up and kept safely in soil, in sheds, during winter. Many will stand in the open ground, with a slight protection of moss, or coal ashes, similar to the hardiest fuchsias. But, with the extra labour involved, the plants will not bloom so early, nor so freely, as those that have been moved and kept dormant in winter. Even the last will not beat young plants kept slowly growing in winter; but then the trouble will be greater, and you must find means for giving light, as well as keeping out severe frost.

VII. *Commelina tuberosa, Mirabilis* (Marvel of Peru), and *Dahlias*, may all be treated similarly. The first is worthy of more general cultivation, on account of its blue colours. The second has nothing of the wonderful and *marvellous* about it *now*, but still a few plants in a small garden are always interesting; and the third everybody thinks he can keep, though I have known many amateurs who have lost their collection year after year. In all, three things, if not essential, are great helps to success. 1st. Growth must be checked artificially, or by frost, before the plants are cut down. 2nd. The roots should remain in the ground some days afterwards; the centre top part, however, protected from wet and frost. 3rd. When the roots are taken up they should be slightly dried, and then packed in dry earth, leaving just the tops exposed, and over which you can throw protecting material in frosty weather. The roots or tubers will thus be kept sound and fresh, and you will escape rotting on one hand, and mummy-drying on the other. When growing in spring, the shoots may be thinned, and the plants potted or planted out at once, to receive a little protection; but in all cases, growth and flowering would be expedited if the plants received a little assistance under glass, in a slight hotbed.

I stop here for the present. It will be seen, that a small room, or shed, with several bins or platforms, one above the another, may thus be made the repository for many useful plants. The more light such places have the better, as it is easy to block up with coverings in severe weather.

R. FISH.

JOTTINGS BY THE WAY.

(Continued from page 63.)

AFTER leaving Coventry I visited Northampton, a town almost as ancient as the former. The neighbourhood is thickly strewed with the seats of the nobility and gentry. The day I arrived I was fortunate enough again to witness an Horticultural and Floricultural exhibition. It was held in the new Town-hall, a splendid, well-

lighted room, and well adapted for the purpose. The plants were well grown and beautifully flowered, especially *Dipladenia crassinoda*, *Aphelandra cristata*, *Allamanda cathartica*, *Russelia juncea* and *grandiflora*, *Crinum amabile*, *Justicia carnea*, *Pteroma elegans*, and varieties of *Lilium lancifolium*, which were exceedingly well grown and bloomed. These plants would not have disgraced Chiswick or the Botanic Regent's-park shows. There was also a fine collection of excellent vegetables, especially Potatoes. One, named *King of Beauties*, was as beautiful as a peach—white skin, size medium, eyes shallow. This was a seedling, exhibited by Mr. Watts, a market gardener. Mr. Watts said that it had never been diseased. He was kind enough to give me one, which I shall propagate as fast as I can, and, if it prove one that will withstand the attack of that fatal disease, the potato-rot, it will be a treasure indeed. There was also a variety known in that locality by the cognomen, *Holland Red*. This also, I was assured by several gardeners, was a hardy variety, not one in twenty being diseased; among ten varieties grown in one garden this was the least diseased of all; it is round, medium size, and reddish skinned. This was exhibited by Mr. Mackie, gardener to E. Bouverie, Esq. I obtained two sets of this variety. *Jackson's Improved Ash-leaved Kidney* is also a fine variety, and was free from disease. These facts are useful; and if every potato-grower throughout the country would notice the varieties that are the least subject to the disease, and publish his notes, a number of valuable varieties would become better known, and might be distributed more throughout the kingdom. Here, as at Coventry, the cottagers' vegetables and hardy fruits were quite equal in quality to the gentlemen's gardeners. And when we recollect that such products must have had great pains, and regular, almost daily, attention bestowed upon them, it is a proof that the encouragement given to cottagers, by giving prizes for their productions, is a great inducement to them to strive to deserve such distinction. By such notice and encouragement, habits of industry are, as it were, incidentally adduced amongst a class of persons who would, probably, without such a stimulus, have spent their hours in idleness, if not in pursuits more demoralizing and injurious to their comfort and that of their families here and hereafter. It is a matter of regret to me, and, no doubt, to many others, that there are so few cottager's prizes given near the metropolis. The London Horticultural Society has begun to give prizes, at their rooms, in Regent Street, for vegetables, and there is no reason why they should not open a class for cottagers especially. I am quite sure the subscribers would not grudge a few pounds a-year for such a praiseworthy purpose. And in large hamlets round London, such as Hammersmith, Highgate, Hampstead, Clapton, Clapham, and others, there are plenty of benevolent clergy and gentry that would be glad to subscribe to have exhibitions purposely to encourage their poor cottage neighbours. If I live, I shall certainly try to establish one at Uxbridge. There is no neighbourhood where cottage gardens are better kept, and they would be still more so if due encouragement were given to the owners. At this (Northampton) show, I had the pleasure to meet my esteemed friend and able coadjutor, Mr. Fish, which was an agreeable surprise indeed. He was there in the capacity of Judge, and our readers will agree with me, a better could not have been chosen. I understand he fills that office here frequently, and I am sure we should be glad if he would give a few jottings by the way when he attends such pleasing meetings. The reports of country exhibitions shows the progress of gardening in various parts, and is always interesting to the garden-loving-reader.

The next day I visited Pinedon Park, the residence of M. Dolben, Esq. The lawn in front of the house is

large, eight or ten acres, I should think. It was planted thinly with all the choice Coniferæ. I was particularly pleased with a healthy specimen of *Pinus patula*, fifteen feet high, and twelve feet through, foliage light green, and elegantly drooping. This species is said to be rather tender, but here it was perfectly hardy, and did not appear to have suffered from frost in the least, every branch being perfect. *Pinus insignis* was thirty feet high, and twenty feet diameter; a perfect pyramid of branches, clothed with healthy foliage of the richest green imaginable. *Cupressus torulosa*, twenty feet high; *C. lusitania*, a rare species in this country, twelve feet; *C. thurifera*, fifteen feet high; *C. macrocarpa*, fifteen feet; and *C. expansa*, twelve feet. *Pinus nobilis*, a handsome, healthy plant, with a strong leader, and short stem, six feet. The great rarity, however, of this place is the *Abies Douglassii-pendula*, a tree unique, and only in this garden; no other place, I believe, possesses a plant of it. In one part of the grounds is a fine dense avenue of old Limes, nearly half a mile long. In walking through this, the spectator might easily imagine he was in some religious edifice, the cloisters of an old abbey, so imposing and solemn is the effect it has upon the senses. Mr. Dolben is justly proud of his choice collection, and spares no pains or expense to add to it every new species of Coniferæ.

Close to the town is an ancient place named De la Pre, the residence of E. Bouverie, Esq. The gardener, Mr. Mackie, two years ago, had occasion to rebuild or improve an old vinery. The vines were about five years old. He took them carefully up, preserving every living root, made a new border, considerably elevated it, replanted the vines, and they were, when I saw them, in most excellent health, with a fine crop of grapes, without a single shanked berry; and, what was more remarkable, they were all of that somewhat tender vine, the Frontignan variety. This was an experiment, and shows what care and judicious management will effect. In the pleasure grounds were some noble Cedars of Lebanon, a gigantic Tulip tree, sixty feet high, which flowers every year; a long yellow-flowered Horse Chestnut; and a fine succession of that rare tree, the *Pinus Ulmaveana*, eighteen feet high.

On the back wall of a forcing house, Mr. Mackie planted, five or six years ago, a number of Roses, chiefly the Provence varieties. These, he said, furnish him with an abundant crop of Roses from February to June. I was much pleased with this wall of roses, and think it worthy of adoption in every garden where cut roses are in request.

(To be concluded in our next).

THE PETUNIA.

(Continued from page 86.)

In my last paper on these showy plants I described the properties of a good variety; I now proceed to give its culture, and trust my remarks and instructions will be useful to such readers of THE COTTAGE GARDENER as may either cultivate Petunias, or desire to do so. The subject may be divided into, 1st, Propagation by cuttings and by seed; 2nd, Soil; 3rd, Summer treatment; 4th, Winter treatment; 5th, General management, so as to render the plants fit for exhibition.

1st, *Propagation by Cuttings*. Petunias are easily propagated by cuttings during nine months in the year; that is, from February to October. The best cuttings are the young tops of rather weakly growing plants. I have always found that cuttings of most kinds of soft wooded plants, such as *Calceolarias*, *Heliotropes*, *Ageratums*, and such-like, when growing very strong with thick succulent stems, soon damp off, especially in early spring, or late in the autumn, and more especially if put

into heat with a view to strike them quickly; whereas, if the cuttings are rather weak, their leaves do not transpire so much, and the cuttings, consequently, live longer without roots, and have time to send them forth before they perish for want of support from the roots. In spring, the cuttings require a gentle hotbed; but in summer and autumn they strike root readily enough in a cold pit or frame. The cutting pots should be prepared in the usual way; that is, drain the pots well by filling them half-full with broken potsherds; upon these place a layer of the rough siftings of the compost, and upon that place a layer of rich, light, very sandy compost, nearly up to the rim of the pot; and lastly, fill up the pot to the level with fine silver sand; then give a gentle watering to settle it and make it firm; and while that is taking place, look out for and make the cuttings; choose, as I said before, young weak shoots, and cut them off close to a joint, dress off the lower leaves so as to allow about an inch to be planted in the sand, and not more than three or four leaves at the top. Plant them with a short stick, pressing the sand closely to each. The pot may be filled with cuttings in rows across it, or, if space is plentiful, place them out round the edge; I prefer the latter method, if circumstances will allow it, but it is not absolutely necessary; for I have now a pot of cuttings, well-rooted, of the true Shrubland Rose, planted and growing all over the surface of the pot—these were put in last August. As soon as the required number of pots are filled with cuttings, observe that the holes made by the planting-stick are filled up with dry sand. Dry sand is mentioned, because it runs more readily into the holes than moist sand would do; then give a gentle watering again, which firmly fastens the sand round each cutting; leave them on the bench for an hour to dry off the surface moisture and any that may be standing on the leaves. After that time, or thereabouts, place them, if in spring, in the gentle hotbed, or, if in summer or autumn, in the pit or frame; shade from bright sunshine, and water when the surface becomes quite dry. In spring and autumn this will seldom be required, but it must not be neglected. A celebrated propagator has often told me, that the proper and judicious watering of cuttings was the grand secret of success in propagation of all kinds of plants, whether hard-wooded or soft-wooded, from the most delicate Heath down to the easily-struck Tom Thumb Scarlet Geranium; and he was quite right. There are more cuttings destroyed by untimely and injudicious watering, than by any other (excepting scalding by too much heat) point of propagation. Therefore, mind the watering-pot, and do not use it too freely upon cuttings until they are fairly rooted, and show evident signs of having made roots and growth. As soon as these appear, give plenty of air, and expose them fully. The spring and summer cuttings should be potted-off immediately when rooted: but those struck late in the year may remain in the cutting pots through the winter, if room is scarce. When they are potted, let the season be when it may, they should be placed in a frame or pit, where they can be shaded and kept close for a few days, until fresh roots are produced; let them then be gradually inured to bear the full light and air.

Propagation by Seed.—The grand object of propagating by seed is to obtain improved varieties; and in order to increase the probability of success, it is advisable to hybridize. Bees and other insects do this for us to some extent, and many cultivators are content with this natural hybridizing; not so the more scientific operator. He observes the deficiency in some property that an otherwise desirable variety possesses, and endeavours to supply or obtain that wanting property from some other variety that has it. This is done by cutting off the pollen cases from one flower, and supplying pollen from the one whose qualities are desirable to infuse into

the one operated upon; and to prevent the insects from bringing any other pollen, the impregnated flower should be covered with fine net muslin. Seed thus obtained is truly valuable, and is almost certain to produce superior flowers. The seed should be gathered as soon as it is ripe, and be carefully cleaned from the seed-vessels, and kept dry and cool through the winter. Sow it in the spring in shallow pans, placed in a gentle hotbed, or on a shelf close to the glass, in a warm greenhouse or propagating-house. When they come up, prick them out in similar pans, rather thinly. This can scarcely be done too early, for if allowed to remain too long in the seed-pan there is great danger of their damping-off. When they have made three or four leaves, then pot them singly into thumb-pots; and as soon as there is no fear of frosts injuring, then plant them out in a nursery-bed till they flower, and choosing such as are really good, throw the rest away.

(To be continued.)

WALKS AND EDGINGS FOR SUBURBAN GARDENS.

(Continued from page 88.)

IN continuation of the subject of Suburban Gardens, which last week we left in a simple, roughly-trenched-over manner, it becomes now a duty to study the direction of walks, the disposal of trees, and other things.

Walks, in a general way, run in lines parallel to the outside boundary, if the latter be straight, if not, the walk must not be forced to take every abrupt turning which circumstances may have given to the fence, but may be carried a considerable distance away from it, rather than give those intricate "ins" and "outs" which descend into "the frivolous;" and the direction being fixed on, the formation is next. This subject has attracted much attention of late, some great authorities asserting, that a foundation of more or less depths of rough stones, &c., was not only unnecessary, but absolutely hurtful, and insisting on the walk being composed of a few inches of concrete, asphalt, or some other mixture analagous to them; the advantages of this description of walk, they say, is a smooth, hard surface, and the prevention of weeds. Now this latter qualification is really of less importance to the suburban gardener than to that of the country gentleman; the former, having but little ground to operate upon, rarely grudges the labour it costs, if he takes a delight in it: while the latter may, in other respects, be so taxed, as to be anxious, by all legal means, to get rid of this impost. On the other hand, the materials for an asphalt or concrete walk are more generally at the command of the townsman than of the country horticulturist; the former, surrounded by all the substances required, can readily obtain some one to lay them down in a mechanical manner, which, if done well in other respects, may serve many years; but I never saw any yet that perfectly pleased me: the unyielding hardness is such as to be painful to walk upon, when slightly covered with fine gravel, as is usually the case, and the small stones, about the size of beans, are unpleasant (to say nothing else) for tender feet, while, in wet weather, the imperious nature of the walk renders the fine portion of loose stratum at top, a sort of puddle, which remains so until the superabundant moisture is carried off by evaporation. Now these evils are not easily overcome in those mechanically-formed walks, even when they are done in the best manner; while it too often happens, that the absence of something in the affair, or the undue presence of something else mars the whole matter, and the walk breaks up in flakes. If, therefore, good gravel is to

be had at anything like a reasonable rate, I would advise the amateur to have recourse to the old, but time-honoured way of making walks, as practiced in years gone by. The site being fixed, and the edging, if of box, planted, some little excavation will be necessary. Six inches will do, unless there are other reasons for making it deeper—as the obtaining the soil from its foundation, or the burying of rough stones and other materials otherwise difficult to get rid of. In that case, any depth you like may be gone into, taking care, as you advance to the top, that smaller and closer fitting ones be used, and, what is equally important, those to which worms have an antipathy may then be more freely used, and brickbats, or small stones, with mortar adhering, or mortar, in some shape, may be thrown in amongst the stones. Clinkers, or rough cinder-ashes, are equally obnoxious to this class of underground enemies: but whatever is used, be sure that a fair share be added, as nothing disfigures a walk more than unsightly worm casts, and nothing is more likely to prevent this disfigurement, than the abundance of such offensive substances as noted above. Rough gravel will follow next, and then that which is firm. Now, though gravel may be said to be requisite, yet I have formed very good walks without it; two or three inches of rough stones, like road metal, being covered with coarse black (or any other coloured) sand, so as amply to hide all the stones, and the surface being rolled and made smooth, about an inch or so of white shells was laid on: this makes, perhaps, the most pliant walk of any, the shells soon getting broken, and every shower washing them to the top, making the best appearance of anything for walks, and after rain, or even when it is raining, they are in better order than at any other time; and weeds are more easily removed than when on a hard, firm-setting gravel. I would strongly advocate the use of shells to all who are within reach of them, and they are conveyed very cheaply to all parts accessible by water communication.

Temporarily with the formation of walks is that of edgings, which, in a suburban kitchen garden, cannot be better than of box, which thrives in most situations; a brick, or other fancy kerb-edging, is sometimes used, but the abundance of other objects of a mechanical nature renders something green a relief to the monotonous lines of brick and mortar. Box-edgings will not, however, thrive in every situation; I have seen it planted with its roots laid into the border, instead of the walk, as is usual, and it still refused to grow well, dying off in frequent large patches. In some soils the conditions necessary to insure the welfare of this and other things may be absent, hence the failure. Now these peculiarities cannot properly be expressed by the terms light, heavy, or medium soils, because I have seen box-edgings thrive in all these, and when the two opposite are at the greatest extreme too; the cause of failure then lies in something else than is commonly understood. Neither has barrenness anything to do with it, because I have seen box-edging languish and die where the ordinary garden vegetables were flourishing and thriving as well as could be wished; however, I advise the amateur to try box, which, though occasionally refusing to grow as above, yet is, in a usual way, as much to be depended on as any thing that is planted. It may be planted at all seasons, but dry hot weather is the worst. I am against cutting any of its tops when planted, unless it be very jagged indeed, in which case a little may be cut away; the roots may, however, be pruned into order, and if dry weather follows its planting, watering may be resorted to with advantage; and in following up this subject I may remark, that I rarely clip box-edging more than once in the season, which is about the end of May or early in June, or it may be the latter end of that month, if showery weather does not intervene before that time, as that is of more real importance than the state of the

plant. This period, as will be seen, is just about the middle of the summer growth, and consequently an unfavourable time to cut it with regard to the plant's welfare; but if the weather be dull and showery for a few days it soon overcomes that, and recovers so as to make a few short fresh shoots during the season, just sufficient to break the raw clipped appearance a new cut edging has, as well as to give it that healthy green look which contrasts so strongly with the rusty brown one it often has when cut at an unfavourable season. Next to box, thrift forms a cheerful looking line of edge, only it must be replanted every two years. *Gentianella* will do in some places, but it does not do in every case; double Daisies are also used with advantage; but I dislike Strawberries, London Pride, Thyme, and other large growing plants, as unless the walk be very wide and long too (which suburban gardens rarely are) these are certainly out of place. If the above smaller growing plants cannot be made to grow, then a kerb or other mechanical edging must be adopted, of course, which ever one be used, it is imperative that it should be laid down the same time as the walk is made, in order that the latter be no more disturbed afterwards. I have not mentioned turf edgings, which rarely find their way into a kitchen garden, unless where the walks are of that material, which, however, is unsuitable to the small spots designated suburban gardens. The preparing of ground, and planting permanent vegetable crops will be given next week.

J ROBSON.

VISITS TO SOME OF THE CHIEF POULTRY-YARDS OF ENGLAND.

(CAPTAIN HORNEY'S.)

How many and how various are the thoughts which crowd upon the memory at the bare mention of the name of Knowsley, the baronial residence of him who sways, as his ancestors have often before contributed to sway, the destinies of Britain. But it is of themes other and humbler than those which these historical recollections conjure up that we, who write for the naturalist, the amateur, and the fancier, are destined here to speak. It was at Knowsley that the late Earl of Derby formed, by the labour of a life, that magnificent collection of birds and animals to which science owed so much; which was unequalled as a private menagerie, and surpassed by few, if by any, public establishments of the kind; and which, for the pure love of science, his lordship kept up for a series of years on a scale almost regal. Alas! that we should, with a passing tribute of regret, have to record that his unrivalled collection is numbered "among the things that were," having been, by the unrelenting hammer of the auctioneer, distributed over the world.

Subjects for our humble pen have, however, as it were, arisen from its ashes, for a beautiful and varied assemblage of domestic poultry now occupy some of the enclosures where all that was rare and gorgeous in the feathered creation were once, as we have said, collected together.

Who, of those who have attended the poultry shows which have long existed in the north of England, and which, on account of the increasing interest taken in the objects of them, are extending themselves rapidly throughout the land, has not heard of the name of Captain Hornby, and admired the specimens which he has exhibited? It is to these, then, and to a description of their dwelling-places, that we propose to devote the present paper.

The hospitable cottage of the gallant captain is situated about equidistant from the mansion of Knowsley and the Huyton-gate station of the Liverpool and Manchester railway. Here is a convenient, but rather confined, poultry-yard, of which as much as possible is made, after this fashion which we describe fully for the benefit of those whose space may also be limited. A plain brick building, fronting to the south, and having a roof leaning northwards, is (we speak from recollection) from twenty to thirty feet long, by six or eight wide. Of the height of a door behind, it rises towards the front sufficiently for the lean of the roof. This is di-

vided into three compartments, each ventilated by a kind of wooden chimney, which admits air, but excludes the rain, and the inside is furnished with nests and low perches. On the south side, a small slide, closed at night, allows ingress and egress to the fowls, and on this side are three enclosures, corresponding to the three compartments of the building. These are formed of light, but strong wire, well painted, and may be twelve or fourteen feet long, by eight or nine wide, an alley, or passage, of two feet in width, or thereabouts, permitting visitors to look at the birds, while it prevents them from fighting through the interstices of the net-work. A daily supply of sand, which is obtained close by, keeps all healthy and sweet, and the cleanly appearance of the whole does much credit to the handy little girl who has the care of the poultry located here. Three lots of Cochon-China fowls at present occupy the enclosures we have described. They are bred, we believe entirely, from the stocks of Mr. Sturgeon and Mr. Andrews, and do credit to the races from which they are sprung. They are let out, alternately, for a few hours each day, to roam over the yard and a field adjoining; and thus, while intermixture is prevented, have the full benefit of an extensive walk. To those whose space is small we strongly recommend such an arrangement as that which for these reasons we have described; for it is obvious that three or more varieties of poultry may, by these means, be kept perfectly distinct in a locality somewhat confined. The building is by no means an expensive one, and we anticipate that many young fanciers will be indebted to the Captain for enabling them, by building upon his plan, to extend the varieties of their feathered favourites.

Accompanying our friendly host in a short walk across the beautiful park, which affords, by the way, a view of the noble mansion of Knowsley, we reach some of the enclosures of the quondam managerie. Here is the splendid collection of Spanish fowls which Captain Hornby, almost regardless of expence, has formed; and we do not hesitate to say that, good as are the specimens of his other varieties, these are, beyond doubt, young and old, the flower of his flock. Whoever beats him at Birmingham must have first-rate birds, and shown in first-rate form too. At another place, in that which was once the pheasantry, are his young Cochons, a promising lot, inhabiting splendid quarters. Another walk, equally pleasant and diversified, brings us to a farm-house where one of the game-keepers resides. Here are the Dorkings, turkeys, geese, and Aylesbury ducks, and it is difficult to award the palm where all are of great merit. The speckled Dorkings would do credit to any exhibition, and will be difficult to beat wherever they may be shown. Some other enclosures, at convenient distances, are appropriated to other varieties, all of which must, with the care devoted to them, flourish in walks so healthy and extensive.

Few amateurs can hope, as this imperfect description will show, to possess the facilities which Captain Hornby enjoys for the keeping, each in its purity, of so many varieties of poultry. The arrangements made at his own residence show, however, how easy it is, in a space comparatively confined, to keep two or three distinct breeds. With these, the prudent fancier will be content, preferring excellence in one or two to mere variety of mediocre races, and thanking those few who possess extended means for enriching our exhibitions with the greater number.

That the taste for the pure breeds of domestic poultry is extending itself, we have had repeated occasion to state, and our assertions are more than proved by the increasing numbers of exhibitions and of the varieties shown, as well as by the large prices which first-rate specimens, even of the oldest varieties, still command. Many of our most enthusiastic amateurs are compelled, by space and circumstances, to confine themselves to one variety; and in proportion as their judgment and care are concentrated on a single point, is oftentimes to their success in the production of excellence in that particular breed. To such be all honour, for they do all that their means admit, and even more than, at first sight, such means would appear capable of effecting. But while we give full credit to him who, with slender means, does all that his limited opportunities are capable of performing, it is but fair to accord a larger meed of praise to the fancier who, more fortunate, it may be, in the possession of extended means, yet with increased trouble, anxiety, and toil, effects proportionably greater results. We know of no

one who, on the whole, is better entitled to the credit of having done his utmost, with much judgment, and regardless of trouble or expence, to promote the excellence, and extend the benefits of our best breeds of domestic poultry than Captain Hornby. Thanking him for the urbanity and kindness experienced by ourselves, we anticipate an agreeable and instructive visit for any one who is equally fortunate in obtaining an inspection of the poultry yards at Knowsley, "and so we say most heartily farewell." B.

EATABLE FUNGI.

(Continued from page 14.)

PROBABLY as an article of diet none of the fungi have been so generally and highly esteemed on the Continent as the *Morells*. There are several species of them, and the whole genus is considered free from poisonous properties; some, however, are insipid, and barely eatable; while others, to which our attention will be more especially drawn, as *Morchella esculenta*, *M. patula*, and *M. deliciosa*, are truly excellent.

In Germany they are largely used, and are considered the most delicate and valuable of the fungi; they are seldom eaten alone, or cooked when fresh, but are dried, and in this way may be kept for months or years, and are largely employed in soups, sauces, or gravies, to which they give a high and rich flavour. There are a variety of ways of dressing these most delicious fungi. Paulet gives directions for stuffing Morells with savoury meats, such as pickled pilehards, cray-fish, the flesh of fowls, &c., and says, after they are boiled they are to be served up with champaign, lemon-juice, and bread-crumbs! Persoon, also, gives the following receipts:—

STUFFED MORELLS.—1. Choose the whitest Morells, wash and wipe them well; when quite fresh-gathered, open the stalk at the bottom and fill it with veal stuffing, anchovy, or any rich sauce you please, securing the ends, and dressing between thin slices of bacon. They may be served with a sauce of rich gravy, &c., according to the palate.

2. Having washed and wiped the Morells as directed in the last receipt, stew them for an hour with a piece of ham, and a little parsley, pepper, and salt, adding occasionally a little broth to prevent burning, and when sufficiently done, bind with the yolks of two or three eggs, and serve on buttered toast.

THE LYCOPERDONS (Puff Balls) form another genus, affording abundance of delicious food in many countries, where they abound and spring up after showers with incredible rapidity, some of them attaining enormous dimensions. In Italy and India they are esteemed as great luxuries. The smaller ones may be stewed in a rich beef gravy, either by themselves, or with other esculent fungi, where they are scarce, and may be flavoured with lemon-juice, &c., according to taste. The best method of dressing the large sorts, as *Lycoperdon bovista*, is to cut it in slices, and fry it in fresh butter, with eggs and bread-crumbs. So prepared, it has the flavour of a rich, light omelette; or, as others consider, the flavour of sweetbread. No fungus, says Dr. Badham, requires cooking so speedily as the *L. bovista*, which grows to an immense size, and as it has the power of quickly repairing injuries (being one of the most rapid of the fungi in its growth), Dr. Badham has recommended, where it is found near our domestic dwellings, that a fresh slice should be taken, from time to time, from each fungus, as we require it for the table; for if allowed to remain undressed it soon decomposes, and becomes insipid and unwholesome. When perfectly fresh it is one of the lightest and easiest of digestion.

THE TRUFFLES form another genus equally sought after and esteemed. They vary much in size and colour, being found from nearly white to a dark brown or black. They have a peculiar odour when fresh from the ground, soon making a room, to most people, unbearable, and they will even scent a house for weeks, if allowed to remain exposed in their fresh state, as I experienced when collecting the eatable fungi for the table, while residing at Basingstoke. They are found abundant on the Continent, especially in the south of France and Italy, from whence it is supposed

they are imported into England in large quantities. They are also found in the East Indies and Japan. They are principally used to flavour soups and sauces—(and, in my opinion, may be dried and kept for months or years, and used for the above purpose grated like nutmegs). If dressed in their fresh state, they should be simply washed and boiled in *plain water*, and served up on dry-toast, peeled at the table as potatoes, and eaten with bread and butter, and pepper and salt, in which way they make a good wholesome supper. I have eaten them raw, cut in thin slices and laid between bread and butter.

THE *HELVELLAS* form another genus free from poisonous species, although some are much more highly esteemed than others—some being insipid and tasteless. *Helvella crispa*, *H. lacunosa*, and *H. esculenta*, are the species most esteemed on the Continent. Their flavour is very similar to that of the Morells, and, by some, the *H. esculenta* has been taken for the true Morell; and, in many instances, they are passed for it. They are, undoubtedly, inferior to the Morells, and, unfortunately, are of a tough, leathery, consistence, which, however, is somewhat remedied by soaking them for a night in milk, and afterwards stewing them for some hours. The best way to dress them appears to be—to stew them for four or five hours in a good supply of rich gravy. My method of dressing them was first to chop them as fine as minced veal, then to cover them with plain water in a saucepan, and stew them for about three hours, adding occasionally, for the last hour, flour from the dredger, and fresh butter, pepper, salt, and lemon-juice, to flavour them. They were then served up with dry toast. They are very excellent stewed and served up with hashed mutton.

THE *CLAVARIAS* form another genus producing no poisonous species, and many that are esteemed luxuries. They are a very handsome genus, varying much in colour, which renders them attractive to the collector, and, when preserved in brine, for sale. They are abundantly introduced into the Italian markets, and in many parts on the Continent are highly esteemed as an article of diet. The following receipt for dressing them is given in Dr. Badham's treatise of the *Esculent Funguses of England*. They are first to be stewed with a little butter over a slow fire, afterwards to be strained, then (throwing away the liquor) to be replaced to stew for an hour with salt, pepper, chopped chives and parsley, moistening with plain stock, and dredging with flour occasionally. When sufficiently cooked, the whole to be thickened with yolks of eggs and cream.

The following *Clavarias* are most esteemed—*Clavaria rugosa*, *C. pyxidata*, *C. cinerea*, *C. flava*, and *C. coralloides*.—F. YORKE BROCAS.

(To be continued.)

HONEY-HARVEST ON THE MOORS.

I HOPE it is not too late in the season to invite our apian friends to accompany me, in imagination, on a visit which I had an opportunity of paying early in October, to (I believe I am correct in saying) the largest bee-keeper and honey-dealer on the Northumberland Moors, and I think there are few among them who will not learn something from a description of his autumnal management. Being an old acquaintance, I was soon ushered into the *sanctum sanctorum* of the establishment, the upper apartments or lofts of the house. Around the first room were ranged a number of empty hives, home-made, and all cottage hives, of various sizes, heaps of refuse combs, and, in a recess, piles of the purest heather honey, sealed up in paper equally pure, ready to be dispatched to customers in all parts of the kingdom.* But the point of attraction to the eye of the apian was a row of hives, reversed, and full of combs, containing a large quantity of honey. A glance, however, showed these had not been arranged by their neat artificers; the edges were uneven, many of the centre combs filled with honey, and the side combs empty. In fact, they had been made up from fragments, from such combs as, having contained brood, were unfit for sale. These combs were fixed in empty hives by two small round rods,

* The price of this honey has this season been 1s. 3d. per pound.

thrust from one side of the hive, through the combs, to the other, and thin narrow laths were placed perpendicularly between the combs, to retain them in their proper position; in the evening these were to be tenanted by driven bees. Thence we proceeded to the driving apartment, which was lighted by a small closed window at one end. Here were four men engaged in the operation of driving. Our readers are aware that this is attended with some difficulty when the air has become chilly, and, before this time, the thermometer had fallen at nights to 33°, whilst the Cheviots the following morning were capped with snow! The bees had been brought from the moor about a fortnight previously and placed in the garden, that the brood might be hatched out, and drones were still found in many of the hives. The driving was commenced in the usual manner, an empty hive being placed over the full one, and a cloth bound round the junction. In about ten minutes, when a portion of the bees had ascended, there was a departure from the ordinary mode of driving. The hives were then divided, the upper end being held in a slanting position, and at one point forming a junction with the stock, while the bees, now intimidated and in confusion, were guided and brushed forward with a feather from among the combs. At this stage of the proceedings, the queen not having always ascended, the bees in some hives went streaming briskly up, while in others, their connection between the two hives was, at times, entirely broken; but, in answer to my inquiry whether they did not sometimes entirely fail in dislodging the bees, I was told, that though sometimes it was tedious, and required patience, the hive was *never* left till it was clear of bees. A few flew to the window, and to the owner of only four or five hives they appeared a considerable number, amounting, when several hives had been taken up, to about half-a-pint; but these were gradually grouping in clusters, and in the evening were to be joined to others, for not a life was willingly sacrificed. These hives had only stood the summer; and the object being to obtain as much pure honey as possible from the side-combs, they were mostly of a very large size; the largest eighteen inches in diameter, by thirteen deep, had received a large swarm, which, having been joined by part of another swarm, weighed seven pounds, and, on its return from the moor, the contents weighed five stone, exclusive of the bees. In driving such a hive, the support of the cross-sticks would be almost indispensable. Those intended for winter stocks were much smaller. Families which were not very numerous were to be limited, one queen being removed, and the other retained, according to their merits, for a brief history of the time of swarming, &c., was labelled on each hive.

We next visited the garden, about a quarter-of-an-acre of ground, divided by fruit-trees into four compartments, around which were ranged the hives, and of which the winter stock would be above fifty. While some were inactive and still, others were all bustle and excitement; these were the manufactured colonies, still reversed, with the empty hive tied over them. In about ten days, the combs would be securely fixed to the sides and top by the bees, when the upright props would be removed, and the hive be placed on its winter stand.

Such is the autumnal management which the experience of a long series of years recommends as the most *profitable*. This consideration will demand no advocacy; but surely there are others which should be as potent. If any of our readers still pursue the old and cruel system, will they not pause and reflect before they again apply the brimstone match? Is there not enjoyment in existence to the least in creation? Are there no feelings of gratitude and affection towards our little garden companions, whose active industry has afforded us so much pleasure and amusement, and whose toils may, probably, have contributed to our luxuries? For myself, I re-echo the words of De Gelien, "Je ne les aime pas médiocrement, je me passionne pour elles."

Before laying down my pen, I will make one or two remarks on the accounts furnished by correspondents of THE COTTAGE GARDENER, and for which we owe our thanks, for there are lessons to be learnt from failure as well as success. In the apiaries of "B. B." and "H. T. N.," drones in September are sure signs of mischief of some kind. Liberal feeding might stimulate the bees of a queenless stock to carry pollen, but the problem may have another solution. Are the drones full-sized or dwarfs? If the

latter, there is a queen, but she lays the eggs of drones only. Should "B. B." now join bees with their queen to No. 2 (and I have visions of a palace in ruins, next spring, under the earthen pan), this queen must be dislodged a few days previous to the union. But it appears that "B. B." has had several dislodged families at command, and I would ask, if he has never presented a spare queen to this auspicious hive? Had it not possessed a sovereign, a stranger would have been welcomed with an enthusiasm which might have awakened feelings of envy in the breast of the French President! Does not "H. T. N's" hive No. 1, which is Mr. Taylor's bar-hive, afford facilities for a thorough examination of the combs and bees, by taking out the former on the bars, and so ascertaining its state as regards the queen? In reading the account of the "deadly warfare," my first impression was, that there had been a mistake as to the hive that had swarmed, but to this difficulty, I think, another explanation may be given. It is observed, then, that in summers when honey is very plentiful, bees assimilate readily, swarms unite, and even enter other hives; but in times of scarcity, all their feelings of jealousy, as well as the desire of plunder, are awakened; and, judging from the returns in this apiary, the secretion of honey in the flowers this season had been very small.—INVESTIGATOR.

THE POTATO MURRAIN.

You perhaps will excuse a casual reader, but a close observer, although only a humble individual, addressing you upon the disease of that *root* which, to the poorer classes of society in Great Britain, may be very justly denominated the STAFF OF LIFE. I see, in a recent number of your publication, a very pious letter on the history and culture of the Potato in this country, but ascribing its disease to the introduction of guano. It will be well remembered by many in different parts of England, including Ireland and Scotland, that long before guano was introduced, or even known or thought about, a disease infected the Potato, but more particularly at the planting season, or just after planting, among the sets, which disease was then commonly known as the *dry rot*. It was no uncommon or isolated thing to see only parts of a field or furrows come up. Upon examining the sets that did not vegetate, most of them had entirely decayed, and only the outer skin was left. Various reasons were advanced, and plans suggested, to cure this disease, or prevent a recurrence, such as planting as soon as cut, or substituting a whole potato for a set in lieu of a cut one, in order to prevent the lymph, or *water*, escaping—a system which is now very much followed. You will excuse my simple language, as I wish to make clear what I write to the simplest capacity. I trust to be enabled to show that the disease I write of, dated some eighteen years back, when we had no guano, bears an analogy to the present murrain. Even prior to the above period, I have known the potato slightly diseased at taking-up time thrown aside as not being good and no further notice taken of it.

It seems something singular that the whole science of Europe, practice and theory, philosophy and chemistry, have not yet discovered the cause of this plague, even with the assistance of Moore's and other almanacks to help them. It appears this year, in this island (Thanet), to be nearly as bad as in 1845. Seven years' experience, with the whole of the knowledge of the "Royal Agricultural Society," and prize essays to boot, and no effectual cure or remedy; nay, not even the cause discovered! Eminent practical gardeners and amateurs, down to the veriest clown, all baffled. Surely this is a wonderful mystery; but so it is. Doctors differ, and so do diseases; yet doctors, to cure this, have not been wanting by thousands, with innumerable remedies: but *all have failed*. If the blind lead the blind, both must fall into the ditch; so must all prescribed nostrums, unless the cause of the disease is first discovered; it appears to be making a beginning where it ought to end. You will excuse my using the plain word potato instead of tuber. Honest John Hodge's conceptions are sometimes curious, and his ideas not exactly clear upon all things; he might take it for a new-fashioned drain tile, or, mayhap, he may think it is to grow long Kidnies in, like them gardener chaps

do cucumbers, to exhibit at the flower shows. I am rather surprised to see, in No. 213, Oct. 28, that you are content to let time correct the evil of this plague. You say, "No doubt but that the Potato will one day be restored to them in its original purity, however long the ordeal through which it has to pass: a cure is out of the question." With this I beg to differ: it looks so like despair. I would have shown the original cause of the disease long ago, and without which *time has proved there is no cure*, but those to whom I wrote about it gave me no encouragement; it was left to that ordeal through which it has already passed, and which is yet in store for it. Nevertheless, I will write you another letter (if this finds room in your little publication), and showing the analogy to which I have adverted.—A CASUAL READER.

[Mr. Errington was quite right when he said "a cure is out of the question;" for when the disease attacks a tuber, who will undertake to restore that tuber to health? *Prevention* is what we must strive for. We shall be very glad to receive our correspondent's promised letter.—ED. C. G.]

NORMANDY.

I TAKE UP my pen—as housemaid's say when they write to their sweethearts—for the purpose of sending you a few memoranda on the poultry of this ancient province; but so little new or interesting in that line have I seen during a complete journey through it from east to west, that, although the said pen is a magnificent Canada goose quill from Hudson's Bay, worthy to write an epic in twenty-four books, I shall have to lay it down again before we get to the bottom of the column, unless you permit me to introduce a few other matters which have reference to country life.

As in the Calaisis, all the fowls are a medley of breeds, with here and there some one race predominating in its own locality. In the Pays de Caux, the district extending along the sea on the north of the Seine, the *Spanish* type has the mastery, though nothing like a well-bred Spanish fowl is to be seen. Around Caen, on the other side of the estuary, the *Polish* are in the majority. There is a very large exportation of poultry from the department of Calvados *via* Havre-de-Grace (as I like to see it written); and an inspection of the fowl-baskets, as they are landed from the numerous little steamers, which arrive from Honfleur, from Trouville, from Dives, from Caen, and from Isigny, will treat you to the sight of a great variety of Polish fowls, some with better top-knots than I have seen exhibited at Poultry Shows. You will find bearded, beardless, whiskered, and muffed specimens, black, white, brown, and speckled; so that those original virtuosi whose passions are excited about the beards of Polish fowls, may each select his own particular idol, and fall down and worship it. The poultry of Normandy is famous for its excellence on the table, and after having partaken of an admirable pullet, with watercresses, a philosopher will not spoil his digestion by insisting too positively that she would have been infinitely better with, or without her beard, as the case may be, and as his choice may lie.

The *Turkeys* are still the pure black Norfolk breed, which is so generally cultivated, and varies so little that the race acquires from the circumstance an additional importance in natural history. Was it *the* domestic variety originally imported into Europe? In one respect we perceive the influence of climate; the poults are earlier for the table than in England. Fine birds may be had in August at a moderate rate, and in September they are abundant.

The *Pigeons* also are very large, mostly of a Runtish character, with a dash of the Trumpeter. They are also numerous, and exceedingly domesticated. Blue Rocks and Dovecote Pigeons are less common, and, indeed, are seldom seen. The Cotentin, the rich luxuriant peninsula which extends from Carentan to Cap de la Hague, produces more *Geese* than I had before observed in the north of France, and also makes the most of them; for many of the poor things wandered about half-naked, having lost their feathers by a less easy process than that of moulting.

The most *unlikely* spot in which I ever saw poultry located, was the Digue, or Breakwater at Cherbourg, a gigantic work, of which that at Plymouth is only a reduced copy, so to speak; the one being 4111, and the other 1760 yards in

length. When finished it will have cost seventy millions of francs, or nearly three millions sterling, and is not dear at the price, if we consider the labour it has cost, and the services it renders. It forms a harbour, and protects a bay which would hold almost all the shipping of Europe. It is perfectly insulated, and is built entirely of granite. In the centre is a lighthouse, with suitable habitations for the officers and workmen, *five hundred* of whom reside upon the Digue. From this centre two vast granite arms stretch right and left, each terminating in a large circular fort about half built, but on each of which forts the workmen who labour there live and sleep in temporary wooden buildings; for when the sea is rough, driven by a strong north wind, the arms are impassible; the waves dash over them, and sweep with such violence, that large blocks of granite many tons in weight, which happen to be lying there to complete the edifice, are born away into the bay like pebbles, or dashed together and broken.

On approaching the Digue in our boat, as the lighthouse and central buildings became gradually more distinctly visible, I was prepared for their human occupants, but did not expect to find any of the brute or the feathered creation colonising a more hard bare wall of granite, without soil and without vegetation. However, let man go where he will, he is sure to be followed by certain companions, attendants, and parasites. The natural history of the Cherbourg Digue would be a curious little memoir to draw up: it would remind one of the *Fauna* of those desert islands which Professor Henslow named "Refuges for the Destitute," in respect to their zoology and their botany. Even before we landed, some cocks and hens came forward to display themselves, and strutted along the sharp, straight brink of the Digue. How they contrive to amuse themselves all day long it is impossible to guess, with no earth to scratch in, no dusting holes to bask in, no lawn to ramble over, no thicket or hedge in which to steal a nest; nothing but granite, at which they may scratch and peck to their hearts' content in vain. Next, a couple of dogs made their appearance, and then a cat stole quietly by; for the Digue abounds in rats and mice. The insect world there comprises fleas, of course, whatever else; houseflies I saw while eating an omelette that was kindly cooked for us. In the summer many butterflies make their appearance, and now and then a bee may travel there by mistake. The list of birds is long; I saw swallows, wheatears, and (would you credit it?) a wren.

The fowls might be luxuries of the great folks in the centre, and would not be looked for among the labourers at either end; but after walking something like two miles on one arm of the Digue, and inspecting the immense circular fort, which was rising block by block, and battery above battery, out of the waves of the sea, I was startled by a familiar crow; and there, down amongst the shivers of stone, and the tools, and the heaps of cement, and the wooden sheds, pranced a cock and three or four hens. The men like to be waked in the morning by the voice of their old country companion; and though the view of the opposite coast is exceedingly beautiful, it is too distant to permit them to enjoy the *noises* which belong to such a rich extent of hill and dale.

Poultry keeping at the Digue is to be criticised in one respect. Fowls in the centre would no more think of visiting those at either fort, than they would of flying to the moon; so that a better place of keeping breeds distinct, than these three localities, cannot be found by industrious searching. But the fowls here are of no breed, or any breed. No one cock resembled any other cock, nor any one hen. It is a complete set of experiments in mongrelism.

The forts being at either end, are specially exposed to tempests. Like the rest of the structure, they are founded on rocks that have been cast into the open sea, and piled up till they rise above the surface. In violent storms, the whole Digue can be felt to oscillate and tremble, though it is believed to be perfectly safe *now*. Every squall only settles the stones more firmly in their places, and additional blocks of granite are continually being thrown into the sea, just before and outside the Digue, weather permitting. The forts are similarly protected and supported by large oblong masses of artificial rock, or concrete, made of bricks, stone, cement, and mortar, tossed into the waves when

sufficiently consolidated. Each block costs 1500 francs, or £60, on arriving at its place, which will give some idea of their magnitude. As the sea is beautifully clear, these gigantic heaps of stone can be seen at high-water, and inspected, when the tide is out.

The granite of which the Digue is built is of a cold-looking, light grey, and comes from the Isles Chansey, in the Gulf of St. Malo; the blocks thrown in, to support the foundation, are red, inferior and coarser, and are brought from Fermanville, a few leagues to the east of Cherbourg. I saw two vessels arrive thus laden, and could not think what made them roll and pitch with such a very peculiar heaviness, till they were moored in their required station, under the direction of the commissary. And then the men began heaving the great lumps of stone, each encircled with a necklace of chains, out of the hold, by means of a pulley and ropes fixed to the top of the mast; each heavy mass was swung as near to the outside edge of the deck as possible, freed from its iron ornaments, and then hoisted over the edge with levers, till it overbalanced itself, and fell into the sea upon the spot intended. It was curious to watch the boiling of the waters, and the hissing of the air-bubbles which foamed up afterwards. The whole process was most laborious, and not without danger; it was anything but child's play. Nor would it be any joke for the lobster who happened to be sporting under water on the exact spot where the Titanic lump of granite was about to fall.

A local egg-story must not be forgotten. A Lieutenant in the French Navy told me, that while he was at Cherbourg, a conjuror, or *escamoteur*, who was paying a professional visit to the town, went into the Market-place, and while loitering there, asked an old woman the price of her eggs. She told him she sold them at six sous a dozen. He said that was a great deal too little, and that she did not know the value of the eggs which she had in her basket. He then took one of them and broke it before her eyes, and showed her that it contained, besides the yolk and the white, a forty franc piece—a large gold coin, sometimes called a double Napoleon. He then broke some more of her eggs, and every one of them contained, or seemed to contain, a piece of gold. While this was going on, he offered to buy all her eggs at *twelve* sous a dozen; if she would sell them, he would take every one of them off her hands. But Madame purse-proudly replied that she was not so foolish as to part with such precious eggs as those, with her eyes open, for a mere paltry offer like that, only double what common eggs were worth. Not she, indeed! She should keep them herself. So he went away, affecting great disappointment at her refusal. As soon as his back was turned, the silly old woman began breaking her eggs, one by one, to make sure of the treasures hidden in them. As she went on, she was greatly astonished that she smashed egg after egg without coming to one with a forty franc piece in it, and so she continued, in the true spirit of gambling, expecting that the next venture would draw the prize, till she had not another egg left. She was sitting, beggared and forlorn, in the midst of a mess of crushed egg-shells, and spoilt custard-meat. Of course she then began to cry, and take on. The other market-women crowded about her, and only laughed at her when she told them of the price she had refused for her eggs, and the reason why she refused it. But the conjuror, who had watched the workings of her despair, took pity on her sufferings, and soon returned; and after having had his laugh too, he paid her market-price for the eggs which he had beguiled her into breaking. And as he gave a performance at the theatre that very evening, the trick he played the old woman served him as a capital advertisement, as he doubtless intended; and he had a crowded house, lots of applause, and sacks-full of money. D.

(To be continued).

WILD BEES.

By W. H. Nemman, Esq.

(Concluded from page 89.)

ENEMIES OF THE WILD BEE.

I CONSIDER the common field mouse by far the most destructive enemy of all wild bees;—wherever it finds their nests it destroys them. I had a nest of the *Apis Terrestris*

in my bee garden two years ago, when suddenly, in July, I missed my friends; they were not at work;—on watching for a few moments, a field mouse came out of the hole, and returned; on examination, every bee was killed, and the combs destroyed. But this is not the worst, for these vermin also catch one-half of the queens in the winter, while they are dormant in the earth, and eat them. The forests of England would be well-stocked with wild bees but for the mice. They say that stoats and weasels are also enemies of the wild bee; it may be so, but I never caught them at their nests; and there is one thing quite certain, that the two last-named creatures kill immense numbers of mice. It is most difficult to kill these mice in the fields; for they are far too numerous and too extensively dispersed to be caught with traps. I think the weasel and the stoat are the bee's best friends in the woods, and the cats near villages. The last, and almost worst, enemy of the wild bee is the school-boy! who is constantly, and has been from time immemorial, fond of killing them for the sake of their honey-bag, and as often for pure mischief, and when this is done, in April or May, a whole nest is destroyed.

I think I am entitled to give my readers these words of instruction when I tell them my acquaintance with the "Dumble Dores" is of fifty years' standing. I commenced catching them myself when a child; the first nest I took, and brought home, was in 1798! the last in 1848!

I hope my readers are not tired of these matter-of-fact details of my earliest friends the wild bees. While acknowledging that I have spent many happy leisure hours in studying their history and economy, I trust those of my readers who are not naturalists will not think the pursuit trifling or unsatisfactory, as many do, who are no lovers of these things. For myself I may truly say, that, to this day, I feel thankful that the first fifteen years of my life were spent in the country, and in these pursuits. The old adage, "God made the country, and man made the town," is to me a true saying, for the agency of a Great First Cause is much more apparent in every object around us in the country than in the town;—even in the history of these little insects, how wonderful their preservation during the winter, their frail bodies being, five months in the year, in the cold, wet earth, and other holes and corners! (I once found one in a small fissure of wooden fence; it was dormant until the beginning of February, when it recovered, and flew away). They rise from their long slumbers, refreshed by their rest, as soon as the sun begins to warm the earth.

The study of the wild bee has this advantage over the hive bee, that young people can follow it without danger; they are not vindictive, and, if properly handled, do not sting, even when defending their young; it can also be followed without cost, except that of time; and who is there that has not a leisure hour each day in the summer? I, therefore, strongly recommend this study to my young friends in the country as an intellectual amusement. Natural history has, of late years, become more fashionable, and this is no mean part of it; besides, it is accessible to nearly all who reside in rural districts; and in the hope it may become so, I take leave of my readers, only adding, that in all the species of wild bees, nearly a uniform system prevails as to the order in the nest: all useless and disabled bees are turned out. Their practice is, "He that does not work, neither shall he eat." Many bees are hatched with defects in their wings, and even without wings, from some disease; these are all turned out to perish. The discrimination of the hive bee in this respect is astonishing. I have often placed a bee, which had defects, on the alighting-board, the guards instantly came up to the intruder, and having held a sort of consultation for two or three seconds, they immediately begin to expel it. But mark the distinction; in showery, cold weather, hive bees are often knocked down and benumbed near the hive, and remain in a state of torpor, from which, if not recovered, they will die of exhaustion. I have a thousand times placed these bees on the board near the entrance, the guards rush out as before, but, on examination, although the bee is unable to walk, they do everything to assist the benumbed insect. By some unmistakable instinct, they directly discover that he has no bodily defects! and admit it into the hive after it has recovered by the heat at the entrance!

In conclusion, we may certainly consider bees as among

the wonders of the natural world. "We know in part," yet how little does each one of us know, not probably a thousandth part of the great volume of the stores of natural history! The whole subject leaves us lost in contemplation at the stupendous nature of that Being who is the projector of them all!

TO CORRESPONDENTS.

ORCHARD HOUSE (J. S., Newcastle-on-Tyne).—Yours is a bold set-out for an orchard house; but why leave the ends and front open? We would close it all but about a yard of superficies at the angle at each end. We would also board the front, leaving a space open in the centre of each light, half-a-yard long by six inches wide; and these might have flaps, with a wooden button, to close in bad weather. Have you no escape for heat at the apex? Your fruit arrangement is not first-rate. Cherries and plums may stand the shade of the back wall, but not peaches. We would do thus:—No. 1, Fondante d'Automne; 2, Marie Louise; 3, Beurré Diel; 4, Winter Neillis; 5, Beurre d'Arenberg; 6, Passe Colmar; 7, Royal George Peach; 8, Bellegarde Peach; 9, Elruge Nectarine; 10 and 11, Moorpark Apricots; 12, Shipley's Apricot. On back, inside, six trees, thus—1 Precocoe de Tours Plum, 1 Greengage, 1 Royal Hative Plum, 1 Early Duke Cherry, 1 Late Duke Cherry, 1 Elton Cherry. Outside, at back, Morellos and Currants alternating. The wood must be trained thinly over the roof, at nearly a foot from the glass. The back trellis should have double distance in the wood. Such is our opinion. We are glad to see these things progressing. Pray consult our articles on "Stations," before planting—to be found in back numbers.

PRUNING BUDDED ROSES (Belle).—October and November is the best time to cut back wild shoots that were, or were not, budded the previous summer—then to be cut within six inches of the inserted bud. "The best time for cutting them again," meaning these six-inch stumps, is the beginning of next July. The reason for leaving the stumps is to fasten the young shoots to them which would otherwise snap off with the first gale. It is of no great consequence whether you disbud the stumps or not, but you must stop all shoots from eyes of the wilding, above and below the inserted buds, at the first or second joint, the next season after budding. November or February is the best time to manure them, but manure never comes amiss to them. Cow-dung, so decayed that it will cut like soft putty, and mixed with one-third chopped fresh turf from a good pasture, is the best manure for them.

UNIQUE GERANIUM (S. S.).—February and March are the best months for striking this geranium in heat. In July it strikes freely, full in the sun, or behind a wall; we prefer the sunny side, and a little shading at first. "In a small way," a one-light box facing the south, and having six inches or a foot of light sandy compost, is the safest way to get July cuttings of this and several of the dwarf and delicate sorts. This could be shaded for awhile till the cuttings could stand the sun. The objection to a north aspect is, that if the autumn happens to be cold and wet, cuttings will not strike so well.

WHAT IS POOR SOIL? (S. S.).—All kinds of light, sandy, and gravelly soil, with little or no dead vegetable or organic remains in them; but "soapy clay" may be very poor soil indeed, although not in the sense we use it for flowers. Sand will make any soil poor enough for flowers, and leaf-mould will make any soil rich enough for them, if sufficient quantities are used. The quantities can only be known by inspection.

CAMPANULA CARPATICAS (S. S.).—They never flower in May at all, but from June to September. The Roses *Microphylla* and *Maria Leonide* are not pegged on the principle we object to; they are climbers, and all climbing roses may be trained on the face of the earth, just as well as on the face of a wall, and pegs will then do for nails. Many thanks for the news that these two Roses make beds that flower from May to October in Hants.

FAST-GROWING TREES (A Subscriber, Bromley).—On your light gravelly soil the White Poplar, and the Turin or Lombardy Poplar, are the best to get up quickly to hide the "ugly cottages." For covering wire-work round windows facing the north, no plant is so good as the *Cotoneaster microphylla*, but being a slow grower at first few people use it. Others object to *Ivy*; and then the next best are the evergreen climbing Roses, such as *Myrianthes*, *Princess Maria*, and *Felicite perpetuelle*.

BULBS (S. S. S.).—Many thanks for the remainder of the list; we shall go through the whole of them this winter.

DATURA (Shylock).—A Datura that is only a foot high by the middle of October will not do to be left out this winter, nor next winter either; and it is of no use to dry it and try to save it that way, as it is too young for that experiment. Therefore, as you have no greenhouse, nor pit, nor any space in the house, you have only two events to choose from. Either get a friend to keep it for you in his greenhouse, or let the first smart frost destroy it, and buy a better, or, at least, an older plant, next May.

FLOWER-GARDEN PLAN (W. P. H.).—We recognised your plan the moment we opened the letter. Were it not for the excrescence caused by 8—3, and by 9—9, this plan would be quite faultless in design. There never was a plan more easy to plant and manage than this, and the wonder is how you could possibly contrive to go wrong with it. You were probably misled, trying to imitate the planting of the designer. Committing a fault to escape the consequences of a misfortune put you wrong the whole season. The autumn-sown annuals perished, and to make good their loss you sowed more annuals in the spring, in the very beds where the summer plants were to go. Did any mortal body ever hear of such a daft trick before! And what is the use of asking for our advice now, when you positively do just the contrary of all that you have read in these pages already? In the first place, what was to hinder the removal of the bulbs when the time came for the other planting? No reason whatever. In the second place, try again, and keep to the advice of one book only, and then you will be right. Every book is right according to some notion or other, and every amateur is wrong in trying to work out more than one system at the same time and in the same space. Look to the index for all you want for the fresh start, and after that let us hear from you again, and we engage you shall be right this time.

FLOWER-GARDEN PLANS (A. P.).—We are obliged to keep the engravings to the smallest compass, and to lay down our series to a uniform scale would be worse than useless. No. 1 is applicable to a space of one-quarter-of-an-acre, and not too small for four acres, with suitable accompaniments. You had better not be in too great a hurry, however, till you see a few more of these designs, which will be as various as our stock will afford.

FUCHSIA SPECTABILIS (A Subscriber).—This is a strong two-year-old plant, and has not yet bloomed. Let it have fair greenhouse treatment, and you will probably have bloom in two or three months or sooner. If you do not succeed, you may then in summer plunge the plant under a south wall as you propose; though we have known it fine set against a north wall in summer, and brought into the house in autumn.

TORONIA ASIATICA SICKLY (Mont Blanc).—The house dry, temperature rising from 65° to 70° in the hottest part of the day. The dry atmosphere may be partly the cause. Your frequent ammonia and liquid manure waterings at this season, another cause. A little peat would also be an advantage in the soil in winter, and for winter-blooming the plants should not be more than twelve or eighteen months from the cutting. Your temperature at night should not be below 48°; 5° higher will be better. Mr. Fish detailed how he kept old plants in winter, some time ago, but such rough treatment left the plants like skeletons. A present sacrifice was submitted to produce a future fine effect. From what you state, if you have not young plants, we would lose no time in fresh potting the plant, getting rid of the sour soddened soil, saving all the roots you can, and making rough sandy peat and charcoal a component of your compost.

ACHIMENES (Ibid.).—The leaves sent are just as we should expect to find them. They will always be so at this season, unless, indeed, you have started them late for winter blooming. The appearance indicates either that the season of growth has approached its termination, or that you have scalded them with the sun while the foliage was wet. In either case, your best plan now is to keep the plants in an open, airy place, withhold water gradually, and then turn the pot on its broadside, anywhere, so that the temperature does not fall below 45°. When you want to set the plant growing again, in the new year, turn out the pot, break the soil, and separate and plant the tubers afresh.

GREENHOUSE AND VINERY (Carrig Cathol.).—We do not say anything about the "third time breaking the charm," but beg to assure you that no previous two separate inquiries have come in our way, as, sooner or later, every correspondent and inquiry receives attention. We think that, in the present case, your own judgment and views of economy must decide. You have already got your 7½-foot-long sashes; two of which, joined together, is to form your fixed sloping-roof of fifteen feet. But, as this will not enclose enough of width to suit you, you propose having a glass-roof at the back, so as to widen the house some three feet more, and ask us how long we would recommend such sashes to be. Now, if we possessed the purse-strings, we should have both sides alike—in other words—a span-roof; and then we would have an opaque part in the centre, where all the airing at top would be given. But, waiving the span, and fixing on the short hip, we would recommend the sashes to be about four feet in length, more if you liked it; and now come the other difficulties. You are told that this hipped-roof would make the house colder. Undoubtedly so, every inch of glass will radiate so much heat. You are recommended, therefore, not to discard these short sashes, but to place them at the top of the others, movable, so as to give air thereby, making thus a sloping-roof of 19 or 20 feet; but we do not see how this would greatly economise your heat, farther than having more wall as a retaining power. Were vines, however, your chief object, this, in the circumstances and the size of your sashes, would be the recommendation we would, without hesitation, give. If plants are your chief object, then, if you cannot have a span, then have the hipped, and have it movable, so as you can have abundance of air, unless, indeed, you have other means of giving air in the back wall. This will also be essential in the front wall or front sashes. As economising heat is an object, your house will thus be less exposed to the wind than if the glass had all been of one slope. It is quite true, that you will economise heat and gain width by having a hipped-roof of slate or other opaque substance; but if you put plants in your house, then this, under the opaque-roof, would be of little use, unless as a pathway. If plants are your chief object, would it not be best to compromise the whole matter, by having a hipped-roof, and covers made of wood, asphalt, or tarpaulin, to go over them in all cold weather, and even over part of the roof in front likewise. If laths are placed for such covers to run upon, neither paint nor wood would be injured; and in all places at a distance from the coal-pit, the saving would soon pay for the covers, while the plants within would flourish more.

DISEASED BULLFINCH.—"Your correspondent's (F. L.'s) bullfinch I fear is past a remedy. If it be asthma, linseed is recommended to be given with its food, and soft bread and milk. The linseed is supposed to be demulcent; liquorice-root steeped in water for its drink. But I believe nothing will relieve it. I suspect it is infested with a small parasitic worm, which attaches itself to the wind-pipe or tubes of the lungs by means of its sucker-like mouth, leaving its body hanging loosely or undulating, as it were, in the tubes; this produces excessive irritation, ulceration, wasting of the body, atrophy, and death. The only remedy for this, is shutting the bird in a close box, and subjecting it to tobacco smoke, when, it is said, the worm will be detached from its hold and thrown off; but I must tell you most of the patients die from the treatment, so that it is questionable whether the remedy is not as bad as the disease, as they die from both." WILLIAM RAYNER.

WHITE CINERARIA (W. H. L.).—If it does not produce better blooms in its natural season it is worthless. The petals were thin, notched, and starry, in the bloom you sent.

RABBITS (Philo-Leporidae).—We do not know of any separate work relating to them. We should be very much obliged by any of our readers sending us the results of their experience in the breeding and rearing of these beautiful animals.

HOUSE SEWAGE FOR DAHLIAS (A New Subscriber).—This, mixed with earth, and applied to the soil in moderate quantities, will be beneficial.

POULTRY HOUSE (N. R.).—We shall have a drawing of one published before the year closes, and will give the dimensions, &c.

WHAT IS HEMONY? (Hester S.).—Milton in his *Comus* has these lines:—

"Amongst the rest, a small unsightly root,
But of divine effect, he cull'd me out.
The leaf was darkish, and had prickles on it,
But in another country, as he said,
Bore a bright golden flower, but not in this soil:
—More medicinal is it than that Moly,
That Hermes once to wise Ulysses gave:
Unknown and light esteemed, and the dull swain
Treads on it daily with his clouted shoon:
He called it *Hemony*, and gave it me,
And bade me keep it as of sovereign use
'Gainst all enchantments."

Some think that Milton merely adopted the name from Ovid's *Metamorphoses*, lib. viii., lines 264-5, where the poet speaks of a plant *Hemonia*, its roots, and other parts. Others think with Coleridge in his *Stateman's Manual*, that Milton intended to allegorise the sacramental wine; deriving the name from *aima*, blood, and *ainos*, wine.

CROSS-BRED FOWLS (A Rooster).—It is possible, but not probable, that superior birds may be produced by crossing the varieties, but the pullets so raised must be coupled, we think, with a cock of the same variety as their hen-parent. Your failure in producing superior specimens of a pure breed arose, probably, from your breeding in-and-in—that is, the cock and hens were from the same brood; and then again, to insure further degeneracy, the old cock was coupled with the pullets, his own progeny. The first rule in all stock-breeding is—*Never couple relatives together.*

REMOVING SMELL OF HOUSE SEWAGE (A House Agent).—Mixing gypsum (sulphate of lime), with it as you propose, will partially effect your purpose, which is called "deodorizing;" but a more effective addition would be peat-charcoal. We should recommend you to add some gypsum also.

ADVICE (Grumbler).—We believe that almost every one of your suggestions have been attended to, which is the best evidence that we should not have quarrelled with you, even if we had not anticipated your wishes.

SPANISH AND OTHER POULTRY.—Semper Vigilans says.—"Let me just speak as to my own experience, this being my first year of the above breed. From nine eggs in April, I got seven chicks; nine in May, eight chicks; cut of both, fourteen now live, and one was killed by the mother of the other hatch; being a game hen, the cock setting up his feathers paid the piper. Wanting chiefly eggs, yet combining good fowls for table use, I was led to choose this breed from reading Richardson's work, and also seeing them so highly spoken of at the Birmingham and other shows. My step was at once to get eggs of the best breed then known; as such, half came from Mr. Hornby's stock, half Mr. Peck's, which I intend to cross, and at stated intervals procuring a good cock of fresh blood. It is my intention to see the show at Birmingham, to judge, from observation and opinions gathered, how my birds contrast. Now, in the first place, they are confined to a space eight yards by three yards, wired off, taking in the stable dunghill. My pullets have regularly began to lay in November, if not October, and are still laying; but my Spanish do not promise to lay before December. The cocks of May 3rd weigh 4½ lbs. to 5½ lbs.; pullets, 3½ lbs. Although never a day's sickness, they strike me as far short of what "Richardson" gives you to expect in size. Next: I have anxiously been looking for proof how to breed for table use; as yet, my own plan strikes me as best for such result. Along with the Spanish hen and cock for layers, I think of putting one Cochon and one Dorking hen, of the best breeds, and so allowing them to sit their own eggs for killing. All three being pronounced best, must surely result well. [Quite the contrary; the mixtures will be generally odious]. If, when parties write of weight, they would also give age, and when most suitable for table, the result might be more correctly attained. Should this opinion of quality not be settled before next autumn, the price of my birds shall not prevent me and my friends giving you our candid opinion."

ADVERTISEMENTS (Rector).—We are as anxious as you are to avoid having these bound up in the volume, but we are at the mercy of the advertisers in this respect.

MISTLETOE (B. R.).—To raise this on the tree you wish it to grow upon, cut *underneath* a branch, quite down to the wood, a tongue of bark in this form, **A**; raise up the point of the tongue, and squeeze into it the seeds from a ripe Mistletoe berry, and then let the tongue close down, but do not press it. The best time for this sowing is February.

GRAFTING CRAB STOCKS (Crab Stock).—It is not good practice to remove the stocks now which you propose grafting upon in the spring. Why not let them remain where they are, and remove them after they have been grafted? You may graft upon them any varieties you may prefer.

RHUBARB FORCING (A. B.).—Any of the varieties will do for this purpose, but the *Victoria* being the largest is preferable. Put a chimney-pot, with a piece of board upon its top, over an old-established plant, and whelm over the pot fermenting stable-dung, or leaves, two or three feet thick; or you may make a frame of laths three feet high over a whole row of Rhubarb, and heap the fermenting materials upon that. The time to commence forcing is December. There is no permanent mode of driving away worms from a lawn. Occasional watering with lime-water, and sprinkling with common salt, will keep them from coming near the surface.

PEARS (Verax).—There are three Louise Bonnes, viz., Louise Bonne, Louise Bonne d'Angers, and Louise Bonne of Jersey, all different. *Yellow Calceolarius* shall be attended to.

GREY-SPECKLED DORKINGS.—The Rev. R. E. Morres, Ashcott, Glastonbury, Somerset, will be glad to know where he can obtain these true, and at what price?

GREENHOUSE WITH WEST ASPECT (S. R. W.).—You may grow both vines and plants in this.

LONDON: Printed by HARRY WOOLDRIDGE, Winchester High-street, in the Parish of Saint Mary Kalender; and Published by WILLIAM SOMERVILLE ORR, at the Office, No. 2, Amen Corner, in the Parish of Christ Church, City of London.—November 11th, 1852.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last twenty-five years, the average highest and lowest temperatures of these days are 49.2° and 36.2° respectively. The greatest heat, 59°, occurred on the 18th in 1844; and the lowest cold, 18°, on the 19th in 1841. During the period 83 days were fine, and on 92 rain fell.

LARGE-FLOWERED GRINDELIA.

(*Grindelia grandiflora*.)

THIS is a good addition to *Grindelia*, a well-known Mexican genus of Composite plants (Asteraceæ), with showy yellow flowers. It was discovered in Texas by Dr. Wright, whence he sent seeds of it to the Botanic Garden at Kew, where it was reared, and proved to be no more than a hardy biennial in our climate, reaching from three to five feet high, and blooming till very late in the autumn. There is another plant in this country, erroneously called *Cineraria tussilaginoïdes*, with large yellow flowers, the counterpart of those of this species. The genus was named by Willdenow, after a German botanist called Grindel. The species is well represented in the *Botanical Magazine*, t. 4628, where it is named and described by Sir W. Hooker.

It belongs to Syngenesia Superflua Class and Order of the Linnæan system. Each stem branches into three or four; each branch leafy, and bearing at its top an orange-coloured flower. Leaves alternate, stalkless, spear-head shaped, toothed at the base only; flowers very large; ray florets strap-shaped, with a tubular base; disc florets yellow, tubular, five-toothed.

B. J.

Propagation and Culture.—This is another addition to the long list of Mexican Composites which have appeared from time to time under cultivation, but which were no sooner on the stage than they disappeared again, for which three distinct causes may be assigned. The first is, that these yellow flowers, like a single yellow *Chrysanthemum*, are considered too common-looking since the rage for herba-ceous plants has subsided. Secondly, that seeds are not ripened with us when these bull-eyed plants flower late in the season, as is the case with this *Grindelia grandiflora*, which was in bloom at Kew till the frost of November, 1851, put a stop to them; and, thirdly, that their roots are not sufficiently hardy for our winters.

There are none of the *Grindelias* more deserving of cultivation than this, because it flowers so late in the season. By far the easiest and surest way to increase and keep it would be to make cuttings of it every season in July, under a hand-glass, out-of-doors; and to give the after-culture exactly as for cuttings and young stock of *Penstemon gentianoides*. In the spring, planting six or seven plants in a patch at the back of the mixed border. Any good garden soil will suit it very well, if it is well worked, and is not robbed by the roots of stronger plants.

We are not yet half alive to the benefit that we might derive from hardy subjects in this extensive order, by turning them into double varieties, of which they are, by nature, more capable than any other race. Some one will yet make a fortune and a name out of the *Michaelmas Daisy*, which we almost despise. The *Cineraria* itself will not be of more varied or gay tints in-doors in the spring than the common *Asters* will be then right out in the open air. This *Grindelia* would be an excellent plant to begin experiments upon. The fact that we must keep it in stock from cuttings is as likely as not to change the nature of it, so far as to cause it to throw off a double-flowering seedling some day or other, for this very reason, that we always make a better bed for a plant that requires so much care than for another, even with a better flower that will take care of itself. Another reason is that a plant from a cutting has not so strong a constitution for the first year or two as a seedling plant of the same sort; and we have great reason to believe, that by reducing the constitutional vigour of a plant, and at the same time giving it a higher degree of culture, is as likely to cause its flowers to turn double. That is, if we can sow seeds from it, if ever so few. No one is now so ignorant as to believe that the art of man can ever turn a plant double otherwise than by seedlings.

D. BEATON.

At page 264 of our last volume, we brought down our tracing of Poultry literature to the time of Gervas Markham, in 1631, and we may pass from thence over the whole of the eighteenth century without finding one author whose works deserve quoting upon the subject. We have referred to Mortimer's "Whole Art of Hus-

bandry," published in 1708, and to many others, and find that where they are prolix, they borrow from the ancients, and where they write from their own experience they are brief and unsatisfactory. Thus, Mortimer says, "As for cocks and hens, I shall not enter into a description of the several sorts of them, only advising

you to choose those that are the best breeders and the best layers;" and similar off-hand, half-contemptuous sentences might be quoted from other writers of that century, showing how little was the value placed upon this kind of stock, and that no attention was bestowed upon its improvement.

The first work that we know of shewing the dawn of better attention to this description of farming stock, is Mr. Bonington Mowbray's *Practical Treatise on Breeding, Rearing, and Fattening, all kinds of Domestic Poultry*. This first appeared in 1816. Between which date and the present, we believe it has passed through nine editions; at all events, the eighth, dated 1842, is now before us. The author understood his subject, wrote from experience, and gives us this first evidence of care and system that we have met with in relation to this branch of rural affairs. He says—

"I have, throughout my life, been a breeder and keeper, and also an amateur of domestic poultry, pigeons, and rabbits; at some periods, upon rather a considerable scale; and have, for many years together, kept a register of the results. I have further done that which, I believe, no other man has taken the pains to do—kept a regular stud book for those breeders, scarcely one of which was so poor as to be without a name; and Regulus, Samson, Flea-catcher, Selima, Moreau, Isaac, and Tom Paine, shine with peculiar lustre on my poultry and pigeon list; whilst Corney Buttercup, Adam, Beelzebub, Lucifer, Carolina, Heecuba, make a figure equally splendid and equally useful, among the rabbits. I think *Montaigne* says somewhere, that if a man would sit and describe that which he has known practically, upon almost any subject, he could scarcely fail of being useful. Just so far my ambition extends. Nor is the world entirely without need of advice on this subject, notwithstanding its antiquity, and the multitude of counsellors."

Every page of his volume testifies that he wrote down only the results of experience, and from these, as from other authors, we shall place before our readers a specimen. In speaking of raising early broods, he says:—

"The number of hens to one cock, four to six, the latter being the extreme number, with a view of making the utmost advantage. Ten and even twelve hens have been formerly allowed to one cock, but the produce of eggs and chickens under such an arrangement will seldom equal that to be obtained from the smaller number of hens. Every one is aware that the spring is the best season to commence breeding with poultry, and, in truth, it scarcely matters how early, presupposing the best food, accommodation, and attendance, under which, hens may be permitted to sit in January; but the attempt to rear winter chickens in this climate, even in a carpeted room and with a constant fire, would, in all probability, be found abortive. I have repeatedly made the experiment with some scores, without being able to preserve an individual through the winter, and nearly the same has resulted with respect to pigs, on a damp clayey or marshy soil. This I request should be understood with some grains of allowance in respect to the soils on which my stock of both kinds was reared, in three counties. They were clayey, wet, and benumbing, and my neighbours were in a similar predicament with myself. It is a mere statement of facts. I have referred in the sequel to those dry soils, better adapted to breeding of poultry, as they are also to breeding and keeping of sheep. I give merely my own actual experience, without doubting that many breeders more fortunately situated have succeeded with winter stock, though, in the best situations, winter may bring with it considerable risk. A record, however, of the experimented fact may remain, as a caution to breeders upon unfavourable soils. The following is a remarkable instance of attention and success in winter breeding.

"The late Mrs. Adams, of Ditchford Farm, near Shipton-on-Stour, in Worcestershire, for many years devoted her

time and attention to the breeding and rearing of winter chickens and spring ducklings, with which she constantly attended Campden and Shipton markets, where her poultry was sought by the neighbouring gentry with avidity, and generally fetched good prices; the superiority of this good woman's poultry was proverbial: as a breeder and fancier she stood pre-eminent; her chickens were always ready for the table by New Year's day, and her ducks were earlier in the market than those of any other person in that neighbourhood. This is given, not as a novelty, but as an example of merit and successful perseverance. In the vicinity of most cities and large towns, chicks and ducklings are reared in the autumn for the Christmas market. The business is done by the aid of artificial heat, by stoving, and with covered floors."

Next appeared, in 1845, *Poultry; their breeding, rearing, diseases, and general management*, by Walter B. Dickson. This is far superior, as a compilation, to any other work we know on the subject. There are gathered together, and arranged in its pages, all the information that is scattered through our county Agricultural Surveys, the French works of M. M. Réaumur and Parmentier, &c.; and he includes in his extracts many from Markham, and, indeed, all his English predecessors who wrote of the same subject. The following is a favourable specimen of his writing—

"THE COLOURS OF FOWLS.—The varieties in the sizes, forms, and colours of fowls, are sufficiently striking to attract the notice of the most indifferent observer; while, to those who can find subject of reflection in every production of nature, they may be made an ample source of interesting remark, as well as of amusing experiment. 'If people,' says M. Réaumur, 'are affected with the kind of pleasure so transitory to the most enthusiastic florists, who procure it but for a few days by a world of care and toil continued through a whole year—if they are affected by the variety and fine combination of colours in their favourite flowers, the poultry-yard, when well managed, may be made to offer them endless pleasures of the same description.'

"The greater number of cocks, even those of the commonest breeds, when exposed to the play of the sun's rays, exhibit the brightest colours, in extraordinary beauty, and varied mixture; and even the hens, if the breeds have been select, are often no less worthy of admiration. Some, for instance, have spots distributed with great regularity, and so brightly white as to look silvery; others are termed golden, because they are spotted or speckled with a fine golden orange colour; while the more common colours are varied in a manner almost endless; and, upon the whole, domestic fowls offer a multitude of colours, the several shades of which would be found with difficulty, if they were sought for amongst the birds of the woods or the waters.

"Another peculiarity in the colour of fowls is, that they frequently change in a very surprising manner, from the time when the chicks cast their down to the annual moult of the full-grown fowls. It is, no doubt, the regular process, at least after the second and third moults, for the colours to continue much the same. I have, at present, a hen of the Spanish breed, which has been of a uniform black for two successive moults, but has now her neck, wings, and tail feathers tipped with pure white. I have another which was all over of a silver grey, but has now her head and neck coal black, with a ring of fine white at the base of the neck, while the rest of the body is finely speckled with black and snow white. It is remarkable also, that this change took place in a few weeks, without any obvious moult, so as to cause her to appear anywhere bare of feathers.

"We are told by M. Réaumur, that one of his hens which his poultry-woman distinguished from the rest by a crooked claw, when her coat began to be taken notice of, had feathers of a ruddy colour mixed with the brown so common among dunghill fowls. A year afterwards, this hen was observed to become almost black, with here and there some large white spots. After the second moulting, black was the predominant colour on every part of the body; but strange to tell, upon the succeeding moult, white was the pre-

dominant colour, and only a few black patches about the size of a crown-piece could be observed. Upon the succeeding moult, all the black spots disappeared, and the hen became uniformly of a pure white like that of a swan. As she was at this time old for a fowl, that is, not less than ten years, it might be thought that old age, which whitens the human hair, likewise whitens the feathers of certain birds; but, in that case, M. Réaumur says, the transition from the ruddy to the white ought not to have been made, as it really was, through the black; and he was of opinion, as the hen was still vigorous and healthy, that she might again change her colour, if she lived, to brown or black.

"M. Réaumur makes some interesting remarks on a cock which he observed with more attention than the hen, so as to establish proofs, that the white colours of the feathers were not, at least in that instance, caused by age. The owner of the cock was struck, the first time he moulted, with the singular change in his colour; and for five successive moults, there was always a considerable change of colour. In his first year, he had some of the ruddy brown, mixed with white, so common in dunghill cocks; in the second, he was all over ruddy brown, or rather red, without any white; in the third, he became uniformly black; in the fourth, uniformly white; and in the fifth, when he was presented by the prior of Bury to M. Réaumur as a curiosity, he had white feathers mixed with a good deal of ruddy colour and brown, bordering upon chestnut, his neck, back, wings, and belly, being ruddy; and even where there were white feathers, they were mingled with ruddy ones. During the summer vacation at Paris, M. Réaumur was two months without seeing the cock; but in this period he became so changed as not to be recognisable, his feathers having become all over of the finest white. The following year he had partly white feathers, but the greater portion was ruddy, or rather of a fair red. Here, then, was a transition from white to a light brown, indicating that the whiteness of his feathers was not owing to the number of his years.

"It has been remarked by several scientific observers, that hen birds of various species, but more particularly hen pheasants, put on, under certain circumstances, the plumage of the male. The celebrated physiologist, Mr. John Hunter, in his work on the "Animal Economy," is of opinion that 'this change of character takes place at an advanced age of the animal's life, and does not grow up with it from the beginning.' Mr. Butler expresses a similar opinion still more strongly, namely, that 'all hen pheasants, as well as common fowls, would assume the plumage of the cock, to a certain degree, if they were kept to a certain age.'—(*Mem. Werner. Soc.* vol. iii.) Though this, however, to some extent may be true, the reasons, or rather the accompanying circumstances and changes of constitution, were first pointed out, it is believed, by Mr. Yarrell, who seems to have determined that the change of colour depends on disease, or removal of the ovarium of the fowl. Among seven hen pheasants, whose plumage more or less resembled that of the male, he found the organ in question diseased, with some variation as to extent, and the progress of change observable in the plumage bore a corresponding analogy. At the commencement of this internal disease, the plumage does not seem to be affected, for 'hen pheasants in confinement, and female of the common fowl in the poultry-yard, had been known to have ceased producing eggs two years before any change was observed in their plumage.'

We have yet three or four modern works to notice, and must, therefore, defer our concluding remarks to a future week.

COVENT GARDEN.

It is astonishing how many subjects are suggested to the mind during our observations on the produce offered for sale in Covent Garden Market, and in the preparation of these reports; subjects both of historical and economic, as well as financial interest. There are many articles produced here which recall the names and experience of names honoured in some department of

horticulture, and others which suggest systems by which we may improve and increase our internal resources. Among these last, we have often thought that a great deal might be done by an extensive and judicious planting of the best varieties of fruits. The importation of Apples, Pears, and Plums is every year becoming greater; and, surely, fruit of our own growth, produced in market with all the freshness of recent gathering, must be far more acceptable than that which has been stowed, and heated, and mouldy, and, in many instances, gathered before it is nearly ripe. There was a great outcry, some years ago, when the duty was taken off foreign fruit. Our growers, like a boy flinching under a threatened blow, hung down their hands, at what they thought was an approaching calamity; and, instead of planting more extensively, and withstanding the approach of the foreigner, they cried out for help, and in the midst of their despair quite forgot to help themselves. Within the last few years a re-action has taken place. When the foreign fruit was admitted, prices fell, and the mechanic who had an apple-dumpling only once a week before, had it three times then: the demand and consumption increased; the home-grower had not enough to supply it, and the foreigner, of course, reaped as great an advantage as he did. Our growers began to find this out, and they set to planting more extensively. Still, however, the demand increases; the prosperity of the country, and the increasing comforts and luxuries of the working classes cry, "give, give." Railways bring town to country and country to town, and year after year we find consumption on the increase. Now, the first object to be kept in view in planting new plantations is the varieties of the fruits. The sorts in general cultivation twenty or thirty years ago will not do now; and it is our intention, next week, to allude more particularly to the varieties which we consider best adapted for this purpose, and which will be most remunerative to the grower. Meanwhile, we shall proceed as usual to record the state of the market for the past week.

FRUIT.—The supply of APPLES during the week has been rather short. Many of the growers are holding back in expectation that the supply will be short. There is no doubt that the crop this year is much shorter than last, and prices will be higher, but we question if it will be judicious on the part of holders to overstand the market while they can realise a fair price. The consequence of holding back will be, a considerable rise, and also a large importation, and then comes the usual reaction—a fall. And it ought, also, to be borne in mind, that there are many feeders to London now; fruit is brought from districts in England in the present day which either consumed or destroyed the crop in the olden time for want of an outlet; and a high price will pay to send from great distances. The prices which have been made during the week are, for cooking Apples, 3s. 6d. to 6s. per bushel, consisting of *Yorkshire Greenings*, *Kentish Broadends*, *Catsheads*, *Beauty of Kent*, and *Flower of Kent*. Dessert Apples are making 4s. to 8s., and are *Ribstons*, *Blenheim Pippins*, *Fearn's*

Pippins, Golden Pippins, and Braddick's Nonpareils. PEARS of the common kinds are not so plentiful; the early orchard varieties are getting over, and what come now are chiefly the finer varieties, such as have been planted of late years. The most choice are *Duchesse d'Angoulême, Passe Colmar, Glout Morceau,* and we have observed a few parcels of *Beurré de Rance.* These are making as much as 3s. and 4s. per dozen. Some very fine *Duchesse d'Angoulêmes* make as much as 6s. per dozen. What few there are of the more common kinds make 5s. to 7s. the half-sieve. GRAPES are plentiful; *Black Hamburgs* realise from 1s. 6d. to 5s. per pound, and *Muscat of Alexandria,* 6s. MELONS are plentiful, at 2s. 6d. and 6s. per pound. FILBERTS, 60s. to 65s. per cwt., or retail at 10d. and 1s. per pound. ORANGES are now beginning to come more plentifully; they are, however, rather of a greenish tinge, and make from 6s. to 12s. per hundred.

VEGETABLES.—There is no alteration in the supply of vegetables, and the prices in consequence continue much the same. CABBAGES, 6d. to 1s. per dozen. BRUSSELS SPROUTS, 1s. 6d. to 2s. per half-sieve. CAULIFLOWERS, 1s. 6d. to 2s. 6d. per dozen. GREENS, 1s. to 2s. per dozen bunches. TURNIPS, 1s. to 1s. 9d. per dozen. CARROTS, 2s. 6d. to 4s. per dozen. ONIONS, 2d. to 4d. per bunch. LEEKS, 1d. to 2d. per bunch. CELERY, 9d. to 1s. 3d. per bundle. SCARLET RUNNERS, 2s. to 2s. 6d. per half-sieve. ENDIVE, 1s. to 1s. 6d. per score. MUSHROOMS, 9d. to 1s. 3d. per pottle.

PLANTS AND FLOWERS.—The usual sorts of EVERGREENS in pots are offered, and seem to meet with a ready demand. Plants in pots consist of *Chrysanthemums* of all kinds, *Heaths, Cinerarias, Chinese Primroses,* double and single, *Mignonette,* and *Ficus elastica,* or *Indian-rubber Tree.* The CUT FLOWERS are abundant, and consist of *Scarlet Anemones, Roses, Trachelium cœruleum, Pinks, Heliotropes, Scarlet Geraniums, Stocks, Camellias, Cereus speciosus, Double Chinese Primroses, Jasminum grandiflorum, Gardenia radicans,* and last, though not least, *Orange Flowers!* H.

GOSSIP.

No fact is more certain—and this certainty gives us great pleasure—than that even farmers are becoming more awakened to the importance of *Poultry* as a portion of their stock. Lord Ducie was a considerable buyer of Shanghai fowls at Mr. Sturgeon's sale; other practical agriculturists are following the example of Mr. Moody, Mr. Sturgeon, and Mr. Punchard; and we have no doubt but that within five years the breed of *Poultry* will be so improved, as to make both farmers and poulterers smile over the remembrance of the weedy mongrels prevalent at the present time. The desire to obtain first-rate birds is not confined to one variety; and, as a proof of this, we may state, that a correspondent informs us, that he knows Captain Hornby refused to take thirty-five guineas for three Spanish fowls which he exhibited at Cheltenham. The same

correspondent, writing from near Liverpool, adds this account of another convulsion—

"It may interest you to know, that after a very hot day and evening (very oppressive) we were all roused by a sharpish earthquake at twenty-five minutes past four this morning (Nov. 9th). From the shaking of the windows when I awoke, my impression was that thieves were breaking through the windows. I jumped up, and struck a light, when my wife showed me the bed and curtains heaving and shaking, and the things on the washing-stand were clattering. I think it lasted near two minutes, with a disagreeable rumbling noise. It was felt at Roby, Seaforth, &c.; but a party of keepers, who were out about four miles from here, did not feel it. It was sharper than most I have felt abroad."

Privation and want bring with them so much of suffering, not merely personal but relative, that the heart softens, and the hand is stretched forth to save from them those accustomed even in their infancy to hardships and deprivations. Still more impressive, still more exciting of every benevolent feeling, comes upon us the information that the great in learning and in virtue are similarly pressed down and benumbed by poverty, and such information has just come to us concerning the celebrated German naturalist *M. Nees Von Essenbeck.* Our contemporary, the *Gardener's Journal,* says that the professor,

"On account of his liberal opinions incautiously expressed during the revolutions of 1848 and 1849, was deprived of his professorship, and is now living in a low suburb of Breslau, in a place called a room, over a cow-shed, and without companion or attendant. He is said to be in his 76th year, and literally starving from want. It is further stated that, some time ago, his library was sold to pay some debts; and his dried plants, which are now his only property, and which, although in some branches they are unequalled, he has nevertheless been unable to dispose of.

"It is a melancholy fact, which we would look past and beyond if we durst, but the fact is patent to all, that science does, with rare exceptions, exact this severe penalty from her true and genuine disciples, as a test of their true devotion. Poverty, indeed, often deep and distressing, would seem to be all but an unalterable condition imposed upon those who unreservedly follow the leadings of science.

"It may, perhaps, be urged that Von Essenbeck suffers not for his devotion to science, but for his meddling with politics. Let us even grant that it was quite competent for the government of his country to supersede him in the Chair of Botany, which he had so long and so ably filled, surely his grey hairs and the invaluable labours of his life ought to have secured him, if not a reasonable competence in his retirement, at least sufficient to make the remainder of his life bearable. Instead of this, however, the man who had so long occupied a leading position among the *savants* of the continent—if we are to believe our authority—'is literally starving from want!'"

The fate of *William Gardiner,* whose death we noticed some months since, leaving one orphan boy, is a painful testimony that poverty and science are too often mated. We mention this, however, more especially for the purpose of making known that Mr. G. Lawson, Curator to the Botanical Society, and Lecturer on Botany at Edinburgh, having undertaken to prepare a Biographical Sketch of *William Gardiner,* with selections from his unpublished papers and letters, and notices of those other self-taught naturalists in humble life, who were his local contemporaries, will be obliged by parties in possession of original MSS. and letters bearing upon the subject, favouring him with the use of the same. It is intended to add, in an Appendix (from unpublished

MSS.), Contributions to the Fauna of Forfarshire; also, additions to the Flora of the County, embracing those Plants not recorded in Mr. Gardiner's "Flora" (now out of print), as well as additional localities, &c., for the rarer species. In this department assistance is invited from local naturalists, whose contributions of facts will be duly acknowledged in the work. Communications may be addressed to Mr. Lawson, 7, Hill Square, Edinburgh.

It is too usual to turn from *Rabbits* as profitless animals, and to associate them with the remembrance of various unsavoury smells. Both these arise from mismanagement, for we know of instances where they were most profitably kept; the yard in which they were was perfectly unoffending, and their manure was the best fertiliser of the adjoining garden. That the breeding of rabbits might be made still more remunerative we have no doubt, for the consumption of them is very large, and the importation from Ostend so extensive, that a deputation from the poultry trade recently stated to our government, that the traffic in rabbits from that port finds employment for from 180,000 to 200,000 persons.

Very recently has been published two very unpretending volumes by Andrew Hamilton, Esq., entitled "*Sixteen Months in the Danish Isles.*" We shall only give from them two short quotations, adding the assurance to our readers, that they will find the work one of the most amusing that has been published this year:—

"From the cemetery, the road goes at once into the country. 'Tis a pleasing change, partly, perhaps, because not a sudden one, to come from the burying-ground to the fields where they are sowing the grain for autumn's harvest. There are plenty of nice land-like farms in the immediate neighbourhood of the metropolis; large comfortable establishments, with apparatus fit for laying in provision of all kinds for the longest winter at a hundred leagues from any town, yet they have the chief town at the very door. And now husbandmen marched o'er the furrows, and scattered their precious seed, in the dull bleak afternoon of a cold spring day, when it needed some faith to believe that the season of budding and blossoming was at hand. But in the trees and about the grass there was now a tendency to burst forth and shoot, that gave notice the time of earth's verdure was about to return. Spring is the time when the sower soweth his seed; it happens also to be the time when most human bodies are laid in earth. The fates of the two are wonderfully similar. As I leaned over the paling and looked at the husbandman's field, I knew that, in a few months, the seeds he planted there would have burst forth, renewed and multiplied, and that the scene, by the blessing of Heaven, would be one of redundant life and beauty. And when I turned my head towards the dead wall I had lately passed, and thought of the more dead enclosure within, I knew that there also, one day, would be a similar scene of revivification, even 'there,' as Bishop Taylor saith, 'where the field of God is sown with the seeds of the resurrection.'"

"Harvest was all past save the fruit harvest. This year there happened to be an unusual abundance of apples and pears, but the quality was inferior. The season had, on the whole, not been genial enough to ripen the fruit; but the spring had been peculiarly favourable to its formation, and the quantity was quite prodigious. Owing to these two circumstances, many people did not think it worth while to gather their fruit at all; they took as much as they might be likely to want, and allowed the rest to rot. In many of the gardens and orchards of our neighbours, we trod on walks covered with fallen apples,—a not very desirable or dry kind of gravel. The plenty was so enormous, I did not

wonder at people becoming hopeless of ever housing it, or using it if they did. And it appeared that there was no market for so much fruit in Copenhagen.

"There was no such scene in the garden-walks of my host, who considered it as a despising of God's gifts to take no pains to reap the kindly fruits of the earth. Whatever might eventually be their fate, they were meantime to be husbanded.

"For many days, nay, for weeks, there was no cessation in the plucking, bearing in-doors, and stowing away of apples. The trees in the garden were, many of them, inhabited by one or two human beings, busy from morning to night, filling large baskets. Two men did nothing but carry the fruit to the house. Many times did I marvel at that constant carrying. Come down stairs when one would, and look through the window whatever time it chanced to occur to one, it was impossible to fail seeing the same two men marching from the garden-gate across the court-yard to a door on the other side, and bearing between them the same large hamper piled high with apples. It was as if the men, on reaching their destination, were transported back to go over the same ground again. I used to think it must be a pastime the mansion owners got up for their guest's amusement, or that it took place by enchantment. I remembered the American superstition of Jumbieback,—the evil spirit who assumed the form of a vast plain or prairie. When travellers essayed to cross the seeming muirland, he allowed them to get on very well during the day, but at night, when they stuck up their tents, he would give a quiet hitch, and transport them back to the self-same spot they had left in the morning, so that they might traverse the treacherous prairie till the day of their death, and never advance one step. I was ready to think my two apple-bearers had got upon Jumbieback.

"Up, above the highest floor of the mansion, it seemed there was a series of attics which were used as store-rooms. There, one of the ladies presided for many days over the disposition of the fruit, until she announced that she abhorred even the smell of apples.

"There was proportionally a like plenty of pears which were the only fruit we thought worthy of being eaten. In the forenoon and in the evening, we used to consume them as heartily as we could; but we made little progress. Each day saw large loads afresh brought in; so we fell upon a clever plan. In the morning, when we took our walks, it was resolved to bear a moderate-sized basket filled with ripe pears for distribution among such of our humbler neighbours as we might meet, or whose cottages we might pass. I carried the basket, but when a cottager hove in sight, I delivered it to one of the ladies, knowing that she could dispense its contents more wisely than I, and that they would be more welcome from her hand. In the course of our round, of whatever length it might be, we always contrived to empty our basket. The attention on the part of the gracious Misses was evidently very well received by their dependents. The first morning of this arrangement, we met, not far from the gates, a large-built peasant girl. "Will you have some pears?" quoth one of the ladies, taking the basket from me, and emptying a good share of its contents into the apron that was at once held out to receive them. The girl spake not a word; but when she had bundled up her apron again about the fruit, with a somewhat theatrical air, as if her gratitude was too great for language, she seized the lady by the arm with her large fist, so that I thought she was going to put Miss's hand into her mouth; but it turned out she was only going to imprint a kiss on it, after which she went on her way.

"One Sunday, when we drove across to afternoon service at the parish church, owing to some error of the clocks, it turned out we had come nearly an hour too early. The clergyman had not yet arrived from his annexed church, at which he had been performing morning service. Coachman was bid to put up the horses, while the Major's asked me whether I would accompany her and her family to call upon the pastor's wife; I acceded.

"In stepping through the garden, I was made aware of the peculiarity in the good lady we were going to see, that, in spite of apparent perfect prosperity, and the absence of all outward calamity, she nevertheless found the world go evermore grievously against her, and her lot full of crooks,

of which she was apt to complain bitterly to all who came within ear-shot. Sometimes she was in such a sea of troubles, that she would hardly admit a visitor.

"We were, however, admitted.

"How do you do, Madame ———?"

"Oh! very middling! Will you sit down, Majoress?" (Here the foreigner was introduced, and made sadly welcome.) "I have just been in Copenhagen; returned on Friday. I ought to have staid longer for my health, for I have been suffering dreadfully from rheumatism; but the weather became so cold after I had been away two days, and as I had left no word here for lighting the stoves, I knew—" (here she mentioned her husband), "must be sitting in the cold, for they could not get the stoves heated without me, and I was obliged to come back to see it done. I was so vexed when I thought of his sitting without fire; I assure you when I thought of him sitting in a cold room, I grew so angry—I was so enraged—I could have—I don't know what I could have done."

"Here the good woman wrought herself into a frenzy, and rolled about on her chair, while we thought she might have spared herself much of the suffering by allowing the servant (or her husband) control enough over domestic matters even to light a stove on personal responsibility. But the pastoress did not suffer any one to rule or even advise in the house,—certainly not her goodman.

"We tried to lead her from the painful theme of the stove, and talked, of course, of the weather, as a gentle change, and other cognate things.

"It has been an excellent harvest," said some one; "there is a remarkable plenty of fruit."

"Fruit!" cried Madame ———; "oh, such an unheard-of quantity of fruit! Did you ever know such a plague? I never saw anything like it. I am sure, before I went to Copenhagen, I did nothing for days together but get the apples and pears taken into the house and put up in the attics; I was so sick of them! And while I was away the pears all rotted, and when I came back the juice had run down through the seams of the floor, and stained all the roof of the room below, and raised such a smell! We have three great pear-trees in the garden, and they bore such a quantity this year. I wish they were cut down;—I wish they were pulled up by the roots. Those wretched pears have spoiled all the ceiling of my room; I wish I had never seen one of them! And all when I was away from home!"

The following is a list of the *Horticultural and Poultry Shows* of which we are at present aware. We shall be obliged by any of our readers sending us additions to the list, and giving the address of the Secretaries.

HORTICULTURAL SHOWS.

BURY ST. EDMUNDS, Nov. 26 (Chrysanthemums). (Sec. G. P. Clay, Esq.)

CALEDONIAN (Inverleith Row), Edinburgh, Dec. 2.

HAMPSHIRE, Nov. 23 (Winchester). (Sec. Rev. F. Wickham, Winchester.)

LONDON FLORICULTURAL (Exeter Hall, Strand), Nov. 23, Dec. 14.

NORTH LONDON, Nov. 23, Chrysanthemum.

SOUTH LONDON (ROYAL), Dec. 9, 16.

POULTRY SHOWS.

BIRMINGHAM AND MIDLAND COUNTIES, 14th, 15th, 16th, and 17th December.

BRISTOL AGRICULTURAL, December 7th, 8th, and 9th. (Sec. James Marmont.)

CORNWALL (PENZANCE), January 10th, and 11th. (Secs. Rev. W. W. Wingfield, Gulval Vicarage, and E. H. Rodd, Esq.)

DORCHESTER, Nov. 24th. (Sec. G. J. Andrews, Esq., Dorchester.)

HITCHIN, Nov. 20th, 22nd, and 23rd. (Sec. S. Goodwin.)

HONIFON, January 12th. (Sec. H. K. Venn.)

WINCHESTER, December 1st. (Secs. G. W. Johnson and J. Colson.)

† For seedlings only.

PINE-CULTURE.

(Continued from page 59.)

It will now be necessary to pursue the subject of after-culture; we will then, if time and space permit, recapitulate the chief features. Before offering any comment of our own, it will be well to take a leaf out of Mr. Hamilton's book, and we may at once turn to page 31 of his truly practical work. He says, as to planting-out Pines: "On February 26, 1828, I planted forty-eight pine plants in the tan-bed, all of which, except one, fruited the same year. The process which I adopted was as follows:—The pit in which they were grown was twenty-seven feet long by ten feet wide inside; two feet of which were occupied by the flues and cavities, which left a width of eight feet for the tan-bed. After all the plants were taken out of the bed, the old tan was levelled, well trodden down, and smoothed with the rake; the whole bed was then covered with fresh tan to the depth of ten inches, the plants were immediately turned out of their pots, with *their balls as entire as possible*, and planted in the bed; they were then *beaten tightly* about the ball, and covered to the depth of one inch only. It will be necessary here to observe, that if the ball, with the roots, be covered too deep, *they will be in danger* of being *burned*. The tan used for this mode of culture must be from British bark, as it undergoes a slower fermentation than foreign tan; and I have always found that as it decays it is rendered less fit for supplying the plants with food. I have tried planting in old decayed tan, but the plants made very little progress; the fruit, also, was of inferior size. Foreign tan is objectionable, as it soon decays. I have been informed that it is mixed with the bark of some of the pine trees; if so, the resinous matter contained in such trees may be injurious to the roots of plants. I am of that opinion; for I have *never found foreign tan answer* for the above system. Plants turned out into fresh British tan, as described, will grow more in four months than in six by any other treatment. The plants, when turned out of their pots into the tan, were about eleven months old. The sorts were principally Montserrats, Black Jamaicas, and a few old Queens; the progress they made during the first three months was really astonishing, and all, except one, ripened their fruit from September to the 1st January. The year following, January 6, 1829, I tried the following experiment. The tan-bed was managed, as I have stated, for those planted out in February, 1828; the sorts were Montserrats, Black Jamaicas, and three or four Queens; and stronger than those of the preceding year, being about thirteen months old when planted in the tan. The same care was taken when turned out of their pots to preserve the ball of earth *with its roots undisturbed*. They were also planted the same depth, and the tan beat tightly about their roots with the hand when planted. In this state they were allowed to remain until the last week in March, at which time *every plant was carefully lifted out of the tan with a long-pronged fork*, by which means the primitive ball was preserved. The roots of some had extended nearly two feet along the surface of the fresh tan, from which they were *carefully disentangled*, and immediately planted in pots *one size larger* than those they were turned out of in the January preceding. After the tan was watered and forked over to the depth of two feet, they were again plunged up to the rims of the pots. *The check* the plants received by being disturbed whilst growing so vigorously may be easily conceived; and they, consequently, all showed fruit in the three following months, and ripened in July, August, and September. Not at all satisfied, on account of *the fruit being smaller* than that of the former year, I tried a third experiment, which indeed varied very little from the first. In the latter end of October, 1829, the same pit was again prepared, by

levelling the old tan, &c., and fresh bark to the depth of eleven inches was spread all over the bed; in this I turned out fifty plants, *out of their pots*, with their balls entire, and all perfected their fruit from the beginning of August to the end of October. Thinking, however, a great improvement might be made in this method of planting out in the tan, I tried the following experiment, which *fully answered* my expectations. At the time these plants were showing fruit, I added *two or three inches of fresh tan* all over the roots of twenty, beating it down with the spade; and the beneficial result was shown in the swelling of their fruit. When these were cut, the suckers growing on all the plants were of a prodigious size; and had I then *known the value of their produce*, by letting them remain *attached to the old stools*, their second fruits might have been ripened by the following October."

This is a long extract, but we do not feel called upon to offer an apology, seeing that it is Mr. Hamilton we would fain represent, and it is, perhaps, well that he should speak for himself: our comments thereon will be at least harmless, and the public will be in a position to judge freely for themselves. Before proceeding farther, we would beg attention to the italics, which we have superadded to the original text, in order to direct the eyes of the uninitiated to the chief features of the Hamiltonian plan. And now a few words to illustrate some of these matters before farther details. It will be seen, that the experiments here related were undertaken for a double purpose, viz., to test the productive powers of the pine grown in tan, and to ascertain if pines could be compelled to "show" through the medium of a check, without loss of size in the fruit. The tan matter appears to be established beyond dispute, although, of course, the question still remains whether it is the most desirable medium. This, it appears is, in a great degree, negated by Mr. Hamilton's subsequent practice. Mr. H., however, says in a note, "I used tan at Thornfield, but none in the new house here; but they like the smell of tan."

As to the check producing fruit, this is what, indeed, might be expected; in most fruits with which we are acquainted, a check on a healthy subject, after a fair amount of liberal growth, generally produces this result, light being in due proportion. The tyro may here learn, that in the case of the pine such was not accomplished without deterioration of size; this, indeed, agrees with the experience of all our most celebrated pine growers: the breaking up of the disrooting system some years since was the signal for an abandonment of the "check system."

Again: Mr. Hamilton gives this caution—"I wish also to observe, that when pine plants are turned out in the winter season, their growth is so rapid, that except they have plenty of air and light, the young leaves are apt to blanch. For several weeks after planting, the surface of the tan ought to be frequently stirred with a rake or long stick, to prevent any fungi breeding, to effect the escape of superabundant bottom-heat, to allow the atmosphere to have free access to the roots, and to keep the tan in a clean, pure state."

It may be here asked, why so much about the *tan*, if Mr. Hamilton has ceased to use it? This is a fair question, and we answer, because we think *tan-culture* still an open question; and also, because localities differ so much. Those who live next door to a coal-pit will hardly care for tan; but we can imagine cases in which parties would be justified in making a liberal use of it; moreover, Mr. Hamilton himself has never, as far as we are aware, totally repudiated its use, whether as a heating medium or for planting in.

We have been speaking all along of "notes" received from Mr. Hamilton, but we find it expedient to have recourse to his most useful little book; which, indeed,

should be well read by all about to embark in Pine-culture without any previous practical knowledge. Candid readers will readily allow for any little "slips of the pen" for the sake of the breadth of Mr. H.'s views; for no sooner is he studied carefully, than those hard fetters imposed by a time-honoured routine, seem to fall off one by one; and the would-be pine grower speedily acquires an amount of freedom before unknown. This, arising from a perception of its simplicity, makes us fancy that pots, crocks, shifts, composts, &c., are passing away like a dissolving view.

Pages 40 to 48 in Mr. Hamilton's second edition, now on the table, are occupied with experiments strongly corroborative of the planting-out system; in which, of course, pots, potting niceties, with other time-consuming matters, are dispensed with: and it is evident that if even Pine-culture were for the million, either this or some other high amount of simplification must be put in requisition. Of course, space will not permit many more quotations from the book, and we will proceed to finish our observations about cultural matters on the planting-out plan; and in a succeeding paper will just skim over the great essentials; or rather skim the very cream from Hamilton's dish, in order to leave the main features strong on the mind of the reader. After this, we do hope to hear of Pine-culture becoming a necessary portion of every gardening system with the middle classes. This, with the Orchard-house, are, perhaps, the two most prominent features in modern fruit-gardening; and surely THE COTTAGE GARDENER may fairly lay claim to having "performed its mission well" in these things.

We last week thought it necessary, in order fairly to elucidate the subject, to pop a few questions to Mr. Hamilton chiefly on the subject of after-culture on the planting-out system. We will give the enquiries and answers verbatim.

"1st. How long after planting before they require culture?"

Ans. All kinds would be better by a little soil on the surface once a year.

2nd. Do you advocate the use of tan up the stems?"

Ans. I used tan at Thornfield, but not now; they, however, like the smell of tan.

3rd. How about leaf-stripping?"

Ans. Be very careful of cutting your leaves.

4th. How about choice of suckers?"

Ans. Should never destroy a ground-sucker unless the plant was already too low in the bed.

5th. What number retained when plenty?"

Ans. I never leave more than three.

6th. Are they chosen by succession or quality?"

Ans. By quality.

7th. When are they removed or thinned out?"

Ans. I tear all superfluous suckers out when six or eight inches high.

8th. How many to a stool, on the average?"

Ans. Three; two stem-suckers and one ground.

9th. Do you ever water at root?"

Ans. I have watered at root twice this summer.

10th. Any plan for checking size in the crown?"

Ans. They want none."

Our readers will see how much I have to thank Mr. Hamilton; indeed, had he not been a very old and well-known friend such liberties could not have been taken. As it is, the only thing to regret is that we could not have the benefit of a regular chit-chat over the affair: distance, &c., precluded the possibility. Still, it is to be hoped that enough will have been stated to prove a pretty good guide to those seeking information. In our next paper on the subject, which may be deferred for a week or two, we shall work up some useful facts, which will throw farther light on the system: in the meantime, we invite young beginners to put what questions they

deem necessary on neglected points: they best know their own wants.

R. ERRINGTON.

MEETING OF THE HORTICULTURAL SOCIETY.—NOVEMBER 2, 1852.

WERE it not for the novelty of seeing a grand struggle for the prizes offered by the Society for the growth and improvement of the *Chrysanthemum*, no one, round London, would be tempted to go out-of-doors on such a day as this was—dull and dreary, with rain pouring down in torrents the whole day. The spirit of the *practicals*, however, was up to the boiling point, and, rain or no rain, they must see and enjoy the battle like true Britons as they are. So they mustered in great numbers; but, alas! the council of our Society are not of practicals, and of course they can hardly be blamed for not knowing the right time of the year for the *Chrysanthemums* to be in a fit state for competition. They knew that *Chrysanthemums* usually bloom in November, and that was all; and a show on the 2nd or 22nd of the month was the same in their unpractical brains. The editors of Moore's Almanack managed much better than this, by keeping snow out in the dog days! This blundering could not have happened at a worse time in our progress. The *Chrysanthemum* has lately become a fit subject for the gamblers in flowers, who, if they could but cook one prize flower up to the mark, would not hesitate to sacrifice twelve of their best plants; and, what is worse than all, their evil practices, to my own personal knowledge, go a long way to sacrifice the credit of the best gardeners in the country. We have had, lately, excellent treatises on the proper cultivation of this useful flower, in defence of practical gardening, and the Horticultural Society steps in, just at the nick-of-time, to second these attempts, and to stamp their value, and the character of our best gardeners; and, as if to prove their zeal, one of the best-grown collections of *Chrysanthemums* in England may now be seen in their own garden, but all to no purpose; and now it is of no use to try to back out of the scrape by saying that gardeners did not understand the rules. Gardeners did understand the rules, and blame me very much for tempting the Society to offer prizes for things out of season. Well, as I have taken a great deal of interest in the shows and meetings of the Society, enjoyed them myself, and endeavoured to make them useful to others, I must pocket this rebuke, and explain how we may get on better in future. Upon the average of seasons, *Chrysanthemums* are in their prime about the 20th of November, or say from the 15th to the 25th, and one week sooner, or one week later, affects *them* more severely than any other flower that has ever been exhibited; all *practical* men know this. It is true, that in large establishments in the country, flowers are very much in request late in the autumn, when ladies cannot go much in the open air, and that October is the worst month in the whole year for house flowers. As a kind of compromise, therefore, gardeners in such places sacrifice some of their earliest *Chrysanthemums* by a slight forcing, and then all that they will bear is only a cold house, such as a peach-house, or vinery at rest, and the doors open at both ends, day and night, and also the top lights a little open at night and on dull days. On very sunny days the top lights and one of the doors may be shut close, but not during the long dark nights. There is no way that a man could think of but I have tried to get in some *Chrysanthemums* by the first of November, and this is the only way in which I ever succeeded; just the reverse of what one would do late in the spring. I have had the *Queen*, *Bicolor*, and three other old varieties, not now well-known, in bloom by the 25th of October by these

means, but none of the others before the end of the first week in November; therefore, I trembled when I first heard of the Society's resolve to open a competition for them in the first week of the month, but concluded, that, as my practice lay at a distance from London, I might be mistaken, and that the flowers come earlier up here than with us far in the country. To make sure of how this stood was my first aim as soon as I saw the failure of this meeting, and there was no lack of London growers on the spot to consult. After exchanging notes with Mr. Chandler, of Vauxhall Nursery, the best authority in London for this flower, and other growers and exhibitors, it turns out that none of them would expect so early a bloom as myself, and some of them maintain that if even very slight forcing were attempted here, mildew would be the consequence and reward in many places round London. This settled, and knowing that "we must all live and learn," the next *Chrysanthemum* exhibition or competition in Regent-street must be held somewhere between the 15th and 20th of November. Now, I think I need not blush for saying that we had only one solitary plant of the common *Chrysanthemum* at this meeting, and that ought to be noted down as a very early one, and I can say it is a very good one—the name is *Madame Derreux*, a fine-shaped flower, flat and imbricated on the face, and of a buffish-yellow colour.

The value of the pretty *Pompones*, the grand, and great-grand-children of Mr. Fortune's Chusan Daisy *Chrysanthemum*, was never better exemplified than on this occasion. All kinds of *Chrysanthemums* are ten days later this season round London than usual; and we have seen already that we can now depend on these *Pompones* from the middle of October, beginning with *Hendersonii*, which was a brownish-yellow on the last occasion (19th October). The same plant was in fine bloom to-day, and age turned the blossoms to a clear yellow. *Hendersonii* should, therefore, be held in great demand for a mother breeder till we get seedlings that will flower from the first of October. Another peculiarity, and a valuable one, appeared in this race, for the first time, on this occasion—sweet-scented flowers. A beautiful little, light lilac flower, called *Le Maine Bété*, has a delicious scent, something between that of orris root, and violets. It was in a collection exhibited, but not for competition, by Mr. Chandler, of Vauxhall Nursery. He had another one called *Ninon*, which will be a great favourite with the ladies in their nosegays and wreaths, for evening head-dresses. It is as flat as a looking-glass, the first essential for a wreath *Chrysanthemum*. The size is half-way between *Bicolor*, the only one of the old sorts that did not look vulgar in a wreath, and a Bachelor's-button. The colour is a delicate French-white. No flowers are more suitable for making regular nosegays than these button *Chrysanthemums*, particularly the pure white, as *Argentine*; French-whites, like *Le Maine Bété*, the sweet one; and the mottled rose, as *Bouton de Venus*; but the great bulk of them are yet of different shades of yellow and buff. We expect a large muster of them at the next meeting on the 7th December, and then I shall take the names of the best varieties, and mention the most distinct colours.

The great lion at this meeting was a *Hybrid Æschynanth*, from Mr. Pince of Exeter, called *Splendidus*, a well-bestowed name. It is by far the best of the family, and shows what can be done with judicious crossing, for which the genus seems to offer great hopes. I did not hear the parentage of this beautiful cross stated, but it ought to have been told. A practised eye could see that *Grandiflorus* was one of the parents; and when not in flower, the cross might easily be mistaken for that species; and that will sufficiently explain the aspect of the plant. The flowers stand more upright than in *Grandiflorus*; they are also much larger, a

greater number of them in a head, and they all open at the same time in each head. The top part of the flower is a rich, soft, crimson-scarlet, lower down, fading into orange-scarlet; and the bottom of the tube ending in a shaded orange colour; altogether making the richest cross that has appeared since the purplish-crimson water-lily at Chatsworth, called *Nymphaea Devoniensis*. There were twelve plants of it in bloom, all from cuttings this summer; and all in 60's, or three-inch pots, showing what a free bloomer it is. Their heights might be from six to eighteen inches; and the largest heads had from ten to twelve open blooms each. Now, as it is lawful, by common consent, to make large specimens of *Achimenes* from a collection of plants, individually small, by planting so many of them in one pot just as they show for bloom; and knowing that some of our best gardeners cannot flower the stronger *Æschynanthus* but indifferently after they come of age; being also quite familiar with the fact, of which Mr. Pince seems to be well aware, that all *Æschynanthus*, whether strong growers or otherwise, flower much better and with greater freedom on single shoots and in the smallest pots; why might not the law be extended to these beautiful *Æschynanthus* as well as to the *Achimenes*? I mean for competition plants. I recollect very well when the parent of this cross, *Grandiflorus*, first appeared, that I made a large number of cuttings of it about the middle of May, and before they were out of their first shift. They all flowered exactly as did the plants now exhibited by Mr. Pince; but before they were allowed to be seen I made two fine specimens with them, in No. 12-pots, and they were much admired that autumn in the conservatory. The two pots were more than half-filled with drainage, so as not to overwhelm the roots with too much soil; about two inches of very rough peat were put over this; then the little plants with very firm balls were turned out of the small pots, No. 60's; the balls were placed on the rough peat, and the spaces between them filled in with equal quantities of peat, sand, and leaf-mould, without any lumps, the surface of the balls being covered half-an-inch. The tallest plants were put in the middle. When the whole were staked, and had a week or two's growth, they were fit for the Queen; but the upshot of the thing was, that in after-years, my worthy employer, Sir W. Middleton, pretty nigh pulled my ears because I did not, or could not, make him such fine specimens with old plants. The like had happened before that time with *Æschynanthus ramosissimus*, for which I paid five guineas to Mr. Tate, of Sloane-street, or at the rate of one guinea an inch. All this I had forgotten till I saw how cleverly Mr. Pince got up his beautiful cross to surprise the Londoners. But I am perfectly sure that this is the grand secret for amateurs and for many gardeners to make the best of all the species of the genus. It is also by far the easiest, as there is no risk, provided that the plants are not turned out of the little pots until the flowers are near their full size. This will not do, however, for competition, as it is against the law to have more than one plant in a pot.

From Mr. Veitch we had a fine plant of the *Vanda cœrulea* in beautiful bloom; and, as is usual with this liberal firm, they always tell the easiest and best way to manage their new plants. They sent to say that the degree of richness in the flowers of this new orchid is according to the heat applied—the more heat the fainter the colour, and the reverse. This may account for what we saw at the last meeting, two growers having each a different variety of *V. cœrulea*, one with a deeper blue lip than the other. If this can be traced to temperature, this orchid should be treated as a Mexican. At any rate, it always gives pleasure to hear how such things have been managed.

We had also a large plant of *Calanthe vestita*, from

the Messrs. Veitch, having large spreading white flowers on long shoots trained on sticks, each flower having a scarlet eye, so to speak. Also a new stove plant, belonging to the order of Cinchonads, and putting one somewhat in mind of *Pavetta caffra*. Mr. Weeks, the celebrated hothouse builder of Chelsea, and whose name has reached the ends of the earth for his success in flowering the Victoria water-lily in an open pond, sent *Zygopetalum crinitum*, a closer growing orchid, and with smaller flowers than those of *Z. Mackayi*, but otherwise not unlike them. Also *Maxillaria picta*, with flowers as strongly scented as those of *M. aromatica*, and, therefore, very desirable; and *Oncidium ornithorhynchum* with small purplish flowers of no great account.

There was a nice *Hybrid Begonia* from the Society's garden, with a wrong parentage given. No one who has the smallest idea of how the pollen tells in this genus, could go so far wrong as to call this a cross between *Manicata* and *Cinnabarina*. There is not a drop of the juice of *Manicata*, or of any species belonging to that section of the genus, in this cross. Nevertheless, the cross itself is a very desirable *Begonia* flowering at this late season, and it looks as if it were much easier to manage than *Cinnabarina*. I saw some splendid crosses from this genus this autumn, in the west of England, and I know of no plants more easy to cross, or from which better results may be expected.

There were two good specimens of late *Achimenes*, from the Society's garden; the old *Coccinea* and *Liepmanni*, and some good plants of the perpetual *Tree Carnation* in three or four varieties. Every body ought to grow these *Tree Carnations*, as they are called, as they flower late and early, and almost all the year round. They were from the continent a few years back, and very little heard of in country places. *Veronica Andersonii*, with five racemes of lilac and blue flowers, after the manner of *Speciosa*, was also from the Society's garden, and samples of the little carpet-plant, *Cochlearia acaulis*. Everybody is now asking where seeds of this little wonder can be had, but I cannot tell. Most of the Fellows of the Society ought to have it by this time, as well as all the London seedsmen. *Bilbergia Moreliana*, a late acquisition from the continent, is as good as any in this genus, the beauty being more in the broad scarlet bracts which accompany the flower. And, lastly, *Cactus truncatus*, a fine plant in good bloom, telling how close we are on the winter.

Of *Fruit*, we had Pine Apples, Grapes, Pears, Sweet Limes, Mandarin Oranges, Citrons, and white Alpine Strawberries, with a Clingstone Peach, which was sent as a Hybrid between a peach and an apricot!

No wonder that gardeners, after a change, or confusion of tallies, should make mistakes about crossed *Begonias*, when people of education will entertain such absurd notions as that a peach could be crossed with an apricot—or that any plant on the face of the earth can ever be crossed with any other plant not of the same genus. Those who simper out extravagances about "*bi-generic crosses*" merely use hard words as a veil for ignorance.

There were three beautiful *Queen Pines*, from Mr. Fleming, gardener to the Duke of Sutherland, at Trentham, two of which were exactly of the same weight, 4lb. 6oz., the third one was heavier by 8oz. Every pine-grower in the kingdom ought to have seen these, if only to puzzle them to know how he can grow such pines, with crowns not bigger than the head of a starling. Mr. Fleming has some grand secret for throwing the whole strength of his plants into the fruit. Mr. Dodds, gardener to Sir J. Cathcart, Bart., sent two *Queen's Pines* of the very same weight as those sent by Mr. Fleming, and more ripe, with crowns rather less than usual; but a smooth-leaved *Cayenne Pine*, from another grower, put these beautiful *Queens* to the blush—in looks, in size, and in weight. It was 6lb. 4oz., and

as handsome a fruit as ever went to table. Many gardeners cannot grow this pine at all. If it gets the least too wet or too damp in winter it turns sulky, and they cannot bring it round again. There was a basket of the true *West's St. Peter's Grape*, and one of *Muscats*, neither of which would be quite ripe before next Christmas. This rainy, cloudy, and muggy autumn, must have taught a severe lesson to all those gardeners who maintain that late grapes should not be forced. There never was a greater mistake. Keep them from "breaking" as late in the spring as you please, but when they do come into leaf, they ought to have as much heat and moisture as air plants, until the fruit begins to turn colour. Even greenhouse grapes, as the Hambrough, are improved by a push from the first coming of the bunch to six weeks after the setting of the berries.

The *Citron* tribe were from Mr. Piper, gardener to E. V. Digby, Esq., of Mintern, Dorsetshire, I happen to know them both, but I cannot tell who is the best gardener—the master or the man. They are both bests, and their large Citrons and Mandarin Oranges were very much admired at this meeting. A gentleman in the room told me that they grow the Mandarin Orange, at Mintern, in the greenhouse as freely as gooseberries, and that he had a basketful of them last August. *Citrons*, after they lay twelve months in preserve, make a beautiful dish at table, either whole or quartered; if whole, they will keep I know not how long. Ordinary *Limes* are better than Lemons in the kitchen, and, better still in whisky-punch, or anything good and hot with a spoon in it; but sweet Limes, like those from Mr. Digby, are scarce articles, and are as good as the best oranges.

There was a fine-looking *Yellow Turnip*, called the "Orange Jelly," of which they spoke very highly. It was raised by Mr. Chivas, of Chester. *Celery*, *Spinach*, *Kohl Rabi*, *Peas*, and some other vegetables were shown, with a King or Queen of the *Vegetable Marrow* tribe, weighing 108 lbs.—it looked like Burn's "Great chieftain o' the puddin'-race"—a Scotch haggis. D. BEATON.

OXALIS BOWELL, AND OTHER SPECIES.

ENQUIRIES as to these not blooming; and complaints as to their not growing, not forcing, and producing fine foliage but indifferent flowers, I hope will be met by the following short outline of culture.

For this beautiful species, as well as for others the most charming of the family, we are indebted to that land of bulbs and heaths, the Cape of Good Hope. The whole have more or less of a peculiar acid taste, which, when not in excess, is very agreeable. Even the most uninitiated may form some idea of the form of the leaves and flowers of the group by examining those of the little *Oxalis Acetosella*, found often so plentifully in woods, but no idea could thus be formed of the magnificence of the present species, with its large crimson flowers. It is generally described as a plant only a few inches in height, but, though it has no stem, it is no uncommon thing to see the flowers rising on strong stalks to from twelve to seventeen inches in height. Few things will beat it, either in a greenhouse or window, on a fine bright day in autumn. It is generally considered an autumn-flower, but, like many other Cape bulbs, the time of *blooming* depends upon the time of *resting* and starting into growth. By successions, I have had it in bloom for seven or eight months out of the twelve; a *clashing* of the bulbs carelessly together destroyed the arrangement. They can only be brought into this succession mode gradually, as each bulb requires the greater part of a twelvemonth to start, grow, bloom, mature, and rest itself. Forced they may

be, but they do not like it; an anxious amateur would, however, soon get over the little difficulty. Even should his bulbs start much about the same time, yet the keeping of a part as cool as to be safe, and giving the others extra heat, will make in the first season a considerable difference in the time of blooming; this first lot may be then kept separate, and treated in the same manner another season. Thus we have seen it bloom from May to December; the medium between these two extremes is the period when it will bloom best with little trouble. In sheltered situations it might then do out-of-doors. I will confine myself to the growing it in pots.

1stly. *Choosing Plants*.—Prefer growing plants, or even plants finished flowering, but with the foliage green; the reason is, that thus you may be sure of well-ripened bulbs by such treatment as will presently be recommended. Failing such plants in pots, choose the *largest*, *firmest*, and *brownest* looking bulbs you can find. If soft, or bagged with watery juices, the consequence of cutting away the foliage too early, you may get foliage, but your flowers will be weak and scanty.

2ndly. *Starting into growth*.—Unless particularly wanted, I would not advise this being done during the dark months of winter. If growth commences in March, bloom may be expected in June and July. It is best to place the tuberous bulbs, with their small ends uppermost, in pans or saucers covered over with earth, rather dry than otherwise, and just kept in that state. A moist, warm place will cause them to shoot sooner; but in the early part of the season I would not advise an average temperature produced by fire heat above 50°. It is better to hurry growth by closeness, warmth, and yet plenty of light afterwards. As soon, however, as the bulbs begin to shoot, before roots commence to form to any extent, they should be placed

3rdly. *In their flowering-pots*.—These should range from six-inch pots for windows, to those from eight inches to twelve inches for greenhouses. Drainage of course must be attended to. Over the drainage a layer of old dried cow-dung, in small hard bits, mixed with charcoal, will be an advantage. The *soil* should consist of equal parts of sandy fibry loam, and fibry peat, with a little charcoal; but fine plants may be produced from sandy well-aired loam and a little rotten leaf mould, or old cow-dung. The soil should be neither wet nor dry. I must try and explain what I mean. "Oh, something about minding pennies, and pounds will take care of themselves." Well, just so; I am no advocate for the contracted and miserly; but, somehow, without these *littles* we cannot get on in gardening. But to the soil: take half-a-handful and close your fingers over it firmly; if on opening your hand the soil remains all in a piece, shewing the marks of your fingers, but falls to pieces when you lay it gently down on the potting bench, it is just in the right state; if it will not remain in one mass in your hand, it is *too dry*; if, when you place it on the bench, it remains without falling to pieces, it is *too wet*. In the one case, you must damp with a fine rose; in the other, you must dry; and either operation will save you future labour and uncertainty. Fill the pots with this soil to within about two inches of the surface, firming it a little; then place the bulbs, small ends upwards, equally over it; about eight bulbs will fill the largest pot well, and yield a large mass of flowers; but if the bulbs are small, add a few more. Sprinkle in the earth amongst them, and over them so that their points are covered. By-and-by, when the flower-stalks are showing, and the leaves are getting the size of a half-penny, the soil will have sunk a little so as to afford room for a top-dressing of old cow-dung, and over that the fastidious may throw a sprinkling of fine soil just to hide it.

4thly. *Watering*.—Of course you will water none

when the bulbs are not growing; but as they are started and potted moisture will be requisite. Here now will appear the importance of what was just now said about soil. If dry, with common watering when would you get it equally moist? If wet, it would dry and crack on the surface; and ten to one but the first wielder of a water-pail that passed that way would render bulbs and soil alike as comfortable as if they had been sunk a foot beneath the surface of a plashy morass. But use the soil indicated; take the precaution, in addition, to place your pots in a pit or frame where thorough air is admitted, the atmosphere is somewhat close and moist, and if the pot is plunged in ashes, &c., all the better. Then the soil will just be in the position for roots to ramify in; and you may safely lock up the water-can until the leaves, getting to the size of a shilling, begin to show that they need a refresher, and by that time roots and everything will have gone also well, that it would require a peculiar clumsy knack indeed to be able to sour or sodden the soil. As the leaves increase in size, and the flower-stalks shew themselves, more air and water will be needed. Pouring it over the dressing of cow-dung will give strength to the flower-stalks after they have fairly started; and after the first blooms appear, manure-watering may be given twice a week in addition. When the flowering is over and the first withered leaves appear, water must be gradually lessened; but some should be given so long as the leaves are green, giving them during this period a good open position, and allowing the plants to remain in the pots several weeks, if not altogether after the foliage has decayed.

5thly. *Position and Temperature.*—As now indicated, when in a dormant state, they cannot be better than in the pots in which they grow, and turned on their broad-sides to keep the soil dry. But, if for economy, the pots should be otherwise wanted, after the bulbs are thoroughly ripened and partly rested, they may be carefully removed, and packed in dryish earth, and kept anywhere where neither wet nor frost can reach them. The earth, in either case, will prevent the juices of the bulbs being evaporated, which, though it might not oppose the production of flowers, would be apt to deprive them of strength, and the foliage of healthy luxuriance.

The plants grow freely where the average night temperature does not fall much below 50°, with a good rise for sunshine; but when flowering, or advancing towards it, enjoys the clearest sunshine and the highest temperature of our summers. A cold pit may, therefore, be said to be its chief delight from May to the middle of September, where it may have full light and air when blooming, and a slight shade and a closer atmosphere when growing. In October the plant will do best in an open warmish greenhouse. I have never seen it better than in sunny days in November and the beginning of December; but then it stood in a rather dry house,—a combination of a plant-stove and a greenhouse, where the temperature at night was seldom below 50°. Even then, at that season of the year, though the bloom opened in clear days, they never became fully expanded, unless during sunshine. These facts will show our greenhouse and window friends the importance of blooming this plant in summer and autumn.

6thly. *Training.*—I have allowed the flowers and leaves to droop; but, unless the plant was elevated above the eye, nothing was gained by the mode, if even then. The simplest, and perhaps the best plan is to place a number of small slender sticks round the inside of the pot, and also several in the centre; connect these together with fine thread; the leaves and flower-stalks will grow through and among them, and will thus be held fast, while the supporting medium will soon be entirely encircled.

It would have been out of place to have said so much

about *O. Bowiei*, at this season, in this department, were it not that a similar mode of management is applicable to the whole bulbous group of *Oxalis*, with, perhaps, the exception of using more peat for the tenderer kinds. They are mostly all such beautiful things, both for greenhouse and window, that I should be glad both to see and have a collection of them; and most of them can be well grown in six-inch pots, and take up but little room in comparison with *Bowiei*. What, for instance, at this season, in a warmish greenhouse or window, can be more beautiful than *O. lobata*, with its lobed leaves, and large yellow flowers; or *O. sericea*, in spring, with its glittering silky foliage and pretty yellow flowers; or *O. tricolor* during the winter and spring, especially in clear sunny weather? As I have already mentioned, many in time may be made to bloom at any period, according to the time they are rested, but it is not advisable to have many in the dead of winter, as it requires a fair temperature and good light to cause the blooms of the best to expand freely. How interesting might many become in autumn and spring to those friends who have but little space at their command. I will, therefore, conclude with a short list of dwarf kinds that bloom freely in autumn and the first months of winter, in spring, and in summer.

In Autumn.—*Lobata*, mentioned above; *Asinina*, ass-ear-leaved, yellow; *Carnosa*, flesh-coloured; *Fulgida*, crimson; *Hirta*, yellow; *Rosacea*, rose-coloured; *Variabilis*, white and red.

In Spring.—*Sericea*, already mentioned; *Canescens*, hoary-leaved, purple flowers; *Flava*, yellow; *Incarnata*, flesh; *Multiflora*, lilac.

In Summer.—*Fuscata*, brown; *Miniata*, vermilion; *Tenella*, lilac; *Rubra flava*, red and yellow; *Darwalliana*, crimson.

Without adding more, I might recommend *Fruticosa*, a yellow semi-shrubby one, to those having the heat of a cool stove at command in winter, and a greenhouse herbaceous one named *Floribunda*, which is easily increased by suckers and division of the roots; the flowers are simple and pink in colour; but the singularity about it is twofold; first, as the plant grows it produces its flowers and leaves in a bundle at the point of the shoots; and secondly, as years roll on this habit gives to the stem of the plant more of the character of a miniature *Palm* than an herbaceous plant. I have had these stems from a foot to eighteen inches in length, and as smooth as a mop-handle; in fact, altogether the plant was too like the mop, handle and all; but still, in a common greenhouse, with rough treatment, it was scarcely ever destitute of flowers.

Oxalis Crenata, once lauded for its edible tubers, and which seemed driven out of the field by *Oxalis Deppei*, but of which little has been seen or heard lately; so difficult is it to get *artistes* of the kitchen, or gentlefolks either, to patronise new-fangled things, IF OF HOME BRITISH GROWTH; though certainly the flowers and points of shoots were nice and pretty too in a salad; the stems made no bad tart; and the tubers, well dressed, being destitute of acid, were immeasurably better to simple tastes, than many of those unpronounceable *kick-shaws* which epicures make so much of, because they pay so nicely for them. These, no doubt, at the right time will be introduced to the notice of those desiring it, by our able fellow-labourer, Mr. Robson. R. FISH.

CONIFERÆ.

(Continued from page 87.)

JUNIFERS.—A large genus of handsome, mostly hardy shrubs; the commoner kinds are grown in almost every garden, and are well suited for that purpose, both on account of their beauty, and being perfectly hardy;

but they grow best about midway between the mountain-top and a low boggy valley. As might be expected, they were well-known to the ancients, and are mentioned in the Bible in the history of Elijah, who hid himself under a tree of this genus when persecuted by the King of Israel. It is mentioned, also, by Pliny, who says that it grew in Spain to a large size. Large quantities grow in the north of Europe. Some species are found in the same locality as the *Cupressus torulosa* in Asia, on the Bhotan Hills, and some are found in North America, so that few plants of any genus are more widely distributed. Many of the species produce timber, which, though small, is remarkable for its durability. The wood has a strong aromatic smell, and when burnt in rooms is said to be fatal to noxious insects. It is used, also, to give hams and bacon that peculiarly smoky flavour so much esteemed by epicures. It is well-known that Juniper berries are used to flavour the spirits called gin and Hollands. To all these uses the plants of this genus can be applied, hence they are interesting, both on account of classical associations, as well as the various uses to which they are applied. I well recollect one use to which the young branches of *Juniperus savina*, the Common Savin, was applied, namely, to destroy worms in the intestines. I had to swallow a tea-cupful three mornings in succession for that purpose, and it was a good remedy, though a dangerous one, at least, I have been informed so since I grew up to manhood, I, however, never felt any ill effects in taking it, the worst was its (to me) very nauseous taste.

The family of Junipers are well adapted to plant in front of taller-growing Coniferæ in the pinetum. They thrive best in a sandy loam, moderately dry, but will grow in almost any soil not absolutely wet. In the beautiful valley near to Alton Towers, there is, or was, a beautiful avenue of the *Juniperus communis*, var. *Seucica*, or *Swedish Juniper*, on each side of the walk leading to the Chinese Temple. Few plants to form an avenue could have a finer effect. This valley was originally a rabbit-warren, but the late Earl of Shrewsbury had it enclosed, broken up, and formed into pleasure-grounds with the finest effect. On the south side, he built a range of ornamental plant houses, with a terrace-walk in front, overlooking the lower part of the valley; and on the north side he built a Swiss cottage, of considerable size, in which there is, or was, rooms for visitors to sit down and refresh themselves. From the platform, in front of the cottage, the visitor had a fine view of the valley—its walk, avenues, conifers, plant-houses, and a lofty Chinese pagoda in the bottom. When I was there, a real, *bona-fide*, aged Welsh harper lived in the cottage, and favoured us with several ancient airs on his harp. This part of the grounds has always most deservedly been greatly admired. At the head of the valley is a fine marble bust of the earl, with this inscription, "He made the wilderness to smile." It is now nearly fifteen years since I had the pleasure of visiting Alton Towers, and I enjoyed such a gardening treat, that the scene is as vivid in my "mind's-eye" as if I had been there only a few weeks ago. I hear the present earl has improved (?) the place much, and, if all be well next summer, I will go and see, and take some "jottings by the way." Two things I should be glad to see there—a good collection of orchids, and an extensive pinetum. The sides of the valley would just be the site for the latter. This digression was brought about by the Swedish Junipers, so let them bear the blame, whilst I escape by turning to describe the species, individually, of this interesting and beautiful tribe.

JUNIPERUS ALBA (Whitish Juniper). There is, or was, a plant of this name in the Gardens at Chiswick, and that is all I know about it. It is not mentioned in any catalogue; at least, I have not seen it.

JUNIPERUS BERMUDIANA (Bermuda Cedar).—One of the few species of this genus that is not quite hardy in this country, introduced so long ago as 1688. It has lived in the open air, in Devonshire, and probably would exist in Ireland. It is the tree that produces the wood from which the cases for black-lead pencils are made. It is also used largely as partitions for rooms in the West Indies, because insects will not attack it.

JUNIPERUS CANADENSIS (Canadian J.).—A hardy, very low shrub, seldom exceeding three feet.

JUNIPERUS CERNUA (Drooping J.).—This is the *J. flagelliformis* of gardens, and is a drooping, curious tree from China.

JUNIPERUS CHINENSIS (Chinese J.).—A native of China and Japan, perfectly hardy and very handsome, growing, in its native country, to the height of thirty feet; but the tallest I have ever seen here was ten feet. It forms a pyramidal tree, densely clothed with branches and foliage, and ought to be in every collection. It should be planted in a conspicuous situation by itself, so that the eye could see it on every side, because there is no coniferous plant that grows so symmetrical, even, and compact.

There are two varieties, both handsome trees, named respectively *Juniperus femina* and *J. Smithii*, but they are rare.

T. APPLEBY.

(To be continued.)

THE PETUNIA.

(Continued from page 107.)

Soil.—In cultivating plants, the most important point is to procure the proper soil. Formerly, the directions given for most plants in this particular was "good garden mould," but in these days the enterprising and zealous grower of plants requires something more explicit and precise; for most growers are aware that soils suitable and health-inspiring for one plant would be death if given to another. Thus, rich compost, used to pot Heaths in, would soon destroy them, whilst, on the other hand, the soil proper for Heaths, and similar fine-rooted plants, would starve, and very likely kill such plants as Carnations, Auriculas, Polyanthus, and, lastly, Petunias. But then, in order to give a suitable soil for such plants, several kinds of soil must, according to the rule of experience, be mixed together; and this mixture is very properly designated by the word compost, the constituent parts of which are many, to suit the various and numerous plants called florists' flowers.

I think, however, the various composts might be much simplified. Some of the older florists, Emerson particularly, recommend such things as seem absolutely monstrous to pot such delicate plants in,—such, for instance, as sugarbaker's scum, blood, night soil, and other strong stimulants, all of which, he says, should be exposed for such a long time to the atmosphere that I opine very little would remain any way different or more nutritive than well-rotted simple hotbed dung, or, what is still better for more delicate plants—such as Auriculas, for instance—well-decomposed tree leaves, usually called leaf mould. With these few remarks on soils, combined under the name compost, I shall proceed to describe what I have found suits the Petunia as well as need be desired. Loam procured from the surface of a pasture, the grass to be taken with it, and the upper layer two or three inches thick only; to be procured in the earlier part of the autumn. This should be laid up in the compost yard for twelve months, and be turned over three or four times during the year. And here I feel it is my duty to digress briefly to state, that the turning over loam, or any other ingredient in a compost, should never be done in wet weather, and for this

reason—the upper surface being full of moisture, and buried at the bottom of the heap in that state, hardens or runs together into a close, lumpy state, into which the beneficial gases of the atmosphere cannot enter, and, therefore, the turning over the heap is positively injurious, and that to an extent that few amateurs are aware of. Turn over these composts, or the more simple soils, loam, peat mould, vegetable mould, or even dung itself (unless it be stable litter in a very dry state), when the surface is moderately dry. A very good time or season to turn the various compost heaps is in a dry frost, without snow. If during such a time the heaps can be turned over till every part has been frozen in its turn, the soils will then be, when a thaw takes place, in beautiful order, and the work of decomposition will have progressed wonderfully. By having this done properly, and at the right times, I have had tenacious loams mellowed and pulverised, and made fit and in good condition to mix with other lighter ingredients in one winter's exposure. And I have also had tree leaves mellowed and decomposed by such attention, in one year, quite as much so as without such care during frost the same material would have taken two years to bring into a state fit for use. The old proverb, *Procrastination is the thief of time*, applies, perhaps, more to gardening operations than any other business.

The loam for the *Petunia* should be rather light, and should be used whilst the roots of the grasses are visible, that is, about one year after it has arrived into the compost-yard. Of this, as a gardener would say, beautiful loam, take one-half, add to it one-quarter leaf mould, one-eighth well-decomposed hotbed dung, one-eighth sandy peat, and as much sand (river would do) as would give the compost a sandy character. These component parts may either be mixed two or three months previously to the time of potting, or be mixed the very day it is wanted. In both cases, let the mixing or compounding take place when the materials are moderately dry. If there should be a continuance of wet weather, let a sufficient quantity of each be brought into the potting room, or some other place sheltered from wet, a month previously to the potting season, in order that it may dry gradually, and so become fit for use.

T. APPLEBY.

A CHAPTER ON PEAS.

NEXT in importance to the potato, and certainly not less thought of when they first make their appearance, "a dish of green peas" forms a sort of epoch whereby we date the advent of summer, and the introduction of the various products common at that time. Besides, the first dish of green peas is a no less remarkable addition to the table fare than the first game of the season; and though the appearance of the latter may be counted on with a certainty as being forthcoming on a particular day, defined by statute, the introduction of green peas is not in any way secured by such protective laws. Acting, therefore, in the spirit of such liberal enactments, the skilful cultivator of late years has endeavoured to hasten on this crop by all the means he can command, and one of the most important things he looks to is the possession of a good, useful, early kind of pea, to sow at the fitting time. Now, though in this case, as in all others, when anything like a demand exists, there is no lack of variety of names, pandering to the capricious taste of an unsteady public, seedsmen have met their views (or attempted to do so) by multiplying varieties to an endless extent. Of course each succeeding new one is said to be so many days earlier than any that preceded it, which, if they had all proved true, we ought by this time to have had green peas before the usual time of sowing, if we were allowed

to reckon these respective days backwards! It would be as absurd to expect these accumulations of utility realised as it would be to look for railway speed increasing so as to land a passenger safely at the end of a long journey some time before he started from the other, although we have been told of an American who maintained the probability of such a thing happening, from *calculations* he had made of the rapid increase of speed of late years, yet I do not deny that some advance has been made in the right direction in the matter of green peas, and probably further progress may be made that way, so as to induce them to hasten their period of usefulness. At all events, enterprise must be directed that way in some shape, otherwise a retrograde movement will be the consequence. I cannot report any very material change in the earliness of the best variety of pea of the present day, with those in use some twenty years ago, yet they may be a trifle; besides which, unless some new varieties be introduced, the extreme old ones degenerate, the same as fruits and other vegetables; but this anxiety to produce new kinds has gone too far: sorts have been puffed upon us differing in no respects from those preceding them. While this has been done by the careful and conscientious trader, less scrupulous parties have been coining high-sounding names, and issuing half-a-dozen kinds out of one bag, with an avidity which none but John Bull would tolerate. However, there are numerous honourable exceptions to this rule, as well as careful and enthusiastic cultivators who spare no pains to increase the utility of this and other vegetables. To this party we are mainly indebted for the position we stand in as regards quality, earliness, and the other improvements imparted to the objects of their attention, still it must be admitted that peas have not benefited much.

The *Early Frame* of a quarter-of-a-century ago was often found in pod, and fit to gather, about as early as the most fashionable-named kind of the present day; and why not?—the seasons have not changed so much for the better yet, and they are of much more importance to the well-being of a crop than all the horticultural skill of the world, however well directed and applied. The season, by which term I mean the state of the atmosphere, has not undergone any material change; and though we now live in days of steam and galvanism, yet Nature's operations develop themselves in a way which alike baffles our skill to hasten or retard, when the ordinary agents by which she works remain unaided and unchecked.

In the case of peas for the first crop, our object is to promote their earliness; and, in doing so, one of our first duties is to supply them with a piece of ground containing as much warmth as the means we have at command will allow. Now, it unfortunately happens, we cannot do much that way; we cannot impart heat to any great amount, but we can, to a certain extent, prevent its being absorbed or withdrawn. An undue amount of cold stagnant water is at variance with the early production of any crop whatever, therefore, whenever that threatens to prevail, means must be taken to remove it. Ground for early peas must be well drained, either naturally or artificially; if by the former means, so much the better. Shelter, again, tends to warmth. A wall reflects back a considerable number of the sun's rays thrown upon it, therefore, what is called a south border is preferable to an open square, these requisites being at command, and the ground having, by previous digging, &c., been rendered as fine and open as possible.

No time must be now lost in sowing the seed, as, by a number of experiments, I have found the middle of November the best time to sow peas to stand the winter. In doing this, observe to sow them thicker than the usual spring or summer crop, the many mishaps they are

liable to rendering a few more necessary to meet emergencies. This, however, must not be carried into excess, I have seen the fatal results of this—sickly seedlings, rising up as thick as small saladings, become an easy prey to the various enemies they have to encounter in their untoward growth. In sowing in wet weather, or when the ground is very wet, it is very good practice to sow the respective rows as the ground is being dug; and if they are sown a little deeper than usual it is all the better, and the seed being covered with coal ashes is some protection from the enemies they will hereafter meet with, a little soil being added likewise, which, moreover, is often covered with a mixture of soot and ashes when the plants make their appearance—this is to make them more distasteful to the enemies preying upon them. Rows about three-feet-and-half apart are at a distance sufficient for the first crop, which ought not to consist of any tall-growing kind, unless strongly recommended by some one who has had experience in its growth. For my part, I prefer those having the habit, &c., of the old *Early Frame*, as being the best for winter; this useful old sort is evidently the parent of the many kinds now before the world. The last few years I have found *Warner's Early Emperor* the earliest of any that I have sown, and I generally sow some three or four sorts at a time, to test their qualities that way. *Isherwood's Railway* I have heard spoken favourably of, but have not tried it; but the *Racehorse*, *Warwick*, and *Prince Albert*, are all behind the *Emperor*. One thing is to have the seed genuine to its kind; if one-half the kinds we have are taken out of a bag of "Charltons," which, it is feared, is too often the case, we may look in vain for that difference in growth, &c., which constitutes a separate variety.

Observe, that in my attacking the dealer in seeds, I am dealing a blow likewise at those whose rage for novelty or variety prompt them to such a course. What occasion has any one for a dozen kinds of peas? A good early sort, followed by one or two good bearing ones, which had better be of the blue or green varieties, as they are more esteemed at table in a general way, is quite sufficient. Now, in making the above remarks on peas to stand the winter, I am perfectly sensible that in some very cold and exposed situations, the injuries they are liable to, from the elements and other sources, render it a more safe course to sow some in pots, boxes, or other contrivances, in heat, in February, to plant out when the weather admits it. But in all cases where a well-sheltered dry border is at liberty, in a latitude anywhere south of the Humber, it is advisable to sow a good breadth at once. In dry situations, in Kent and other counties bordering London, whole fields are sown at this period to pick for the market of that great metropolis.

In conclusion, I may add, that a few *Beans* may also be sown at the same time, and under circumstances similar to the above. The *Long-pod* or *Hangdown* is more esteemed than the *Mazagan*—though, perhaps, scarcely so hardy or early. J. ROBSON.

"I WANT FOR NOTHING."

By the Authoress of "*My Flowers*," &c.

ONE of the most interesting cases of cheerful and happy affliction that I ever witnessed became known to me a very short time ago, and I wish I could transport some of my readers to the "cottage of content," that they might learn a lesson of thankfulness for the lighter trials they may have to bear, and, at the same time, see what may be done under very adverse circumstances when the heart is right with God.

I was walking a few days ago through part of another parish, when I met a respectably-dressed young woman, with a walking-stick in her hand. I was passing on without taking any farther notice, when she stopped me by saying,

"If you please, can you tell me whether I have passed Mr. Wallis's gate?" I replied, that I did not know who lived in the cottage we were standing near, but that she had passed the gate some little distance; "but," I added, struck by a sudden idea, "are you blind?" "Yes, ma'am," she said, "quite blind."

There is something that touches the hardest, stoniest heart on seeing a person who is blind. Helpless; cut off from so many enjoyments of life; dependant on others for everything; defenceless, and exposed to a thousand perils, the blind are endowed with an interest in the eyes of man that is their strong protection. He who dimmed their sight, gave them another boon in place of it; and when He wills, who can resist the power? On questioning this poor blind woman, I found she lived but a little way from where I met her. She said she knew the roads just about her home so well, that she could venture short distances alone, "and I always find one or another, ma'am, to help me along when I want to go farther; every body is very kind to me." She had, on this occasion, met "One" to help her, for, had she gone a little farther, she would have come to a plank thrown across a stream, which might have caused a fall. But it was ordered otherwise, and I took her safely home. On entering the cottage, a boy about six years old, or, perhaps, more, was seated on a low bench in the corner of an old-fashioned, wide chimney. The poor child was swelled in a most distressing manner with dropsy; and his mother told me the "doctors" had done all they could, but he was no better; he had been so for years, and she believed he would never get well. He sat all day long just as I saw him, his eyes fixed on the ground, seldom moving, never complaining, and not often speaking at all. While I was pitying this poor afflicted child, another bright-eyed creature, younger still, came in with an elder girl. This animated child was deaf and dumb! It was scarcely possible to conceive anything more affecting than this cottage scene! The mother blind; the child almost helpless from bad health; another deaf and dumb! But the mother was so cheerful and contented! so rich in faith! so full of peace and joy, and spiritual consolations, that she seemed, indeed, to be dwelling in a "house not made with hands," and to be fed with meat which the world knows not of. She gave me a sketch of her little history, blessing God continually, as she proceeded, for His abundant mercy to her and hers. She is the mother of eight children, five of whom are living at home. Of these, one boy "keeps himself;" another earns eightpence a-week; and the elder girl receives a loaf and a shilling from the parish, to wait upon her helpless mother and little brother and sister. The father is a steady, sober man, who has worked twenty-seven years for the same farmer, and earns seven shillings a-week, one of which is kept back for rent. They all live upon bread, with a scrape of lard upon it, and sometimes, but very seldom, a morsel of butter. Now and then they can buy a "bit of tea," or coffee, which is the cheapest, and an ounce of coffee lasts them, she said, "a great many times!" With quiet, beautiful thankfulness, the blind woman said they wanted for nothing; sometimes they went without a meal; but she had never been in debt! What they could not pay for they never got; her children never asked for anything more than their mother gave, not even the sick one, "and, bless the Lord," she added, "what a merey that is to me!" The most affecting circumstance of all, is the fact, that the little dumb girl generally leads her mother about! "But," I said, "you are blind, and she is deaf and dumb, how do you ever understand each other?" "When I want to go to the shop, ma'am, I take down the basket, and she knows the meaning, and then brings me safe home again." Can any one of my readers imagine a more touching sight than a blind mother led by a little deaf and dumb child? If they can even read this poor description of it without a throbbing of the heart, they must be less than human beings!

This poor blind creature has lost her sight about two years; but such is her deep, unaffected piety, that she appears as accustomed to her painful affliction as if she had never known what it was to see. It is wonderful what religion does for us; I mean religion of the heart, not that which the world understands. It is one thing to talk; another thing to act; and another thing still to suffer joy-

fully what the will of the Lord appoints. I called one day, and found her suffering from illness. She was sitting without a fire, in a cloak and bonnet, and looking very ill; but her heart-happiness was the same. "I want for nothing, ma'am, bless the Lord. I am not drowthy, and I am not hungry; I want for nothing." Oh! how fully did this show forth the faithfulness of the promise, "he that cometh to me shall never hunger, and he that believeth on me shall never thirst." It is impossible to look in her face, sightless as she is, and not see the evidence of a "peace which passeth all understanding;" and the quiet, simple expression of her feelings is exquisite to hear. Here is no excessive "talk of the lips;" no display to catch the eye and deceive; you feel it is real, and it goes to the heart at once.

The cottage is not one to gratify a tasteful imagination; it is situated in rather a wild but pretty spot,—a sort of green, through which passes a cartway; but the scenery on all sides is lovely, and the neighbouring hills always give a sort of grandeur to the valley at their feet. The inside of the dwelling is not attractive either; the air of the little kitchen is not clean or comfortable, as one would wish to see; but a child of ten or twelve cannot be expected to do exactly as she ought, unless innately clean, which few children are; and the poor blind mother can do little. Still they are better than very many others, and their clothes are neat and mended.

Let us all lay to our hearts the lesson taught us by this cottage scene. Let us look round upon our mercies, our food, our raiment, our possessions. Let us consider our health, our eyesight, the sense of hearing, the power of speech; let us dwell a few moments upon all these things, and then ask ourselves whether we can say as the blind mother does, "I want for nothing."

What is the secret of her abundance? What fills her basket and her store? She quietly makes answer, "The Lord is my shepherd: I shall not want;" "Thou preparest a table before me in the presence of mine enemies: thou anointed my head with oil: my cup runneth over." This is the secret, ever-flowing spring of her peace and plenty. She has *nothing*, and yet she "possesseth all things." This is the secret of *all* peace. We may have plenty in the world; but we cannot have peace *out of Christ*. We may turn and twist the matter a thousand ways, but we shall never get at it, never obtain real peace, until we are "one with Christ," until we can experience, in all its truth and richness, that glorious prerogative, "The Lord is my shepherd." Then we shall be sweetly led to say with the poor blind woman, "I want for nothing."

VISITS TO SOME OF THE CHIEF POULTRY YARDS OF ENGLAND.—No. 3.

(PENZANCE).

[The following has appeared in the *Cornish Telegraph*, but was obligingly communicated to us by the author.]

PENZANCE contains several collections of poultry, which would do credit to places where their several merits have long been subjects of emulation.

Among those whose ardour has been specially kindled in this pursuit is Mr. A. Blee; and the result of his observation at Birmingham leads him to regard the Cochinchina race as those most deserving of his care. It would be difficult, indeed, to point out any better lot of pullets than those he now possesses, excellent both as to colour as well as figure. As regards the former, they are mostly fawn and light buff; the neck-hackles in some cases being slightly pencilled, and the legs of all feathered throughout with the same tint. In shape they are robust and compact, with a fine head, and well-proportioned legs. A pullet hatched February 27th in the present year weighed 7lbs. 2oz., and many others were above 6lbs.

Mr. Blee's enclosure is divided only by slight wire net three feet high, which proves that the Cochinchinas have one great merit, viz., that of being retained within bounds by fences which would be altogether disregarded by other fowls. Opposite to this goodly bevy, and in full view, appear the cockerels and their sires, the two latter being admirable

specimens, the one bred by Mr. Sturgeon, and the other by Dr. Gwynn; of blood, therefore, as pure as any fancier can desire. The birds of the year would warrant expectations of their attaining even greater size than their parents; for while the cocks, which are about 16 months old, weigh each 10½ lbs., a young cockerel hatched in February last had already reached 8½ lbs.

Some prettily marked golden spangled Polands, with capital tufts, and fortunately, as we think, *unbearded*, make an agreeable contrast to the lighter colours of the Cochinchinas.

Mr. Blee has given great attention to the original selection and subsequent management of his stock, which promises, however, amply to repay all his care. The following list of the respective weights of some of his Cochinchinas, cockerels and pullets, hatched on February 27th, in the present year, and others in March, speaks favourably for their early maturity.

COCKERELS.		lbs.	oz.

" 4	7	2
" 5	6	4
" 6	7	12
" 7	7	0
" 8	6	12

A hen of last year was now taken off her nest, and put into the scales, which gave 7lbs. as her weight. At Christmas last she was well up to 9lbs., and this would probably be about an average loss after laying any considerable number of eggs and then sitting.

A singular instance of the good qualities of the Cochinchinas as layers occurred in the case of a Punhard hen, sold by Mr. Blee to a gentleman at Illoggan. Having reached her new home, she laid the next day, and continued to do so, till in ninety-six days she had laid ninety-five eggs; in twenty more days she laid ten more eggs, making in all 105 eggs in 126 days. She then took her nest, sat well, and reared a large and healthy brood.

About 100 head of poultry at present form Mr. Blee's collection, and this is in course of almost daily reduction, from a general desire of amateurs and others to avail themselves of so good a stock. They are certainly well cared for, a four-roomed cottage, with commodious lofts attached, being devoted to their accommodation, with a large exercising area railed off for them in an adjoining field.

Mr. Blee gives it as his decided opinion that, in proportion to their weight, the Cochinchinas are not larger consumers of food than other fowls.

Mr. Lawrence was another of the early members of the Penzance Society, and resolving to decide for himself on the competing claims to excellence of different varieties, he is now enabled to decide on their several merits from personal experience. His Cochinchinas came from the stock of Mr. Andrews, of Dorchester, a most successful exhibitor. The parent birds are certainly worthy of their origin, but their progeny we think bid fair to surpass them.

WEIGHTS AND MEASUREMENTS.—COCHIN-CHINAS.

		lbs.	oz.

" 2.	Ditto, hatched April 8th	7	8
" 3.	Light Cockerel, hatched March 28th	9	8
" 4.	Pullet, hatched April 8th	6	8
" 5.	Hen	8	2

Somewhat more compact in form than the larger varieties, Mr. Lawrence's older birds are distinguished by great symmetry, and a more prevailing tint of cinnamon in their plumage; but the chickens from them have given colours as light as could be desired. It is a curious circumstance respecting Cochinchinas, that the offspring of a dark cock and light hen, or *vice versa*, constantly produce colours as light, or even *lighter*, than when the parents are both of them light-coloured birds.

Mr. Lawrence is fortunate in the possession of a run for his birds in a walled garden near the Roman Catholic Chapel, in addition to his poultry-yard at home. But other claimants now demand our attention, and with good cause. Some *Spanish* are before us with the perfect white cheek, so characteristic of their breed, and the graceful carriage so peculiarly their own. Their character, in an economical point of view, standing so high, no wonder they come into competition with Cochin-Chinas and other favoured races. But, meritorious as are the specimens it now contains, Mr. Lawrence's poultry-yard, we are given to understand, is about to receive a valuable addition in this class from the hitherto unrivalled stock of Capt. Hornby, R.N. We wish him success with them, such as his past efforts have undeniably merited.

But our catalogue of Mr. Lawrence's poultry-yard is yet far from completed. Here are *speckled Dorkings*, as good as we need desire; and the Malays, which although first-class birds, must, we fear, share the fate of their race by gradually yielding to the greater merits of their oriental neighbours, the Cochin-Chinas. Here also are specimens of the birds that excited our admiration at Truro—the *White Indian Game* fowls, the beauty of whose form we cannot but admire, though altogether ignorant as to their possession of the courage of their English relatives.

The meaning of the word "*pencilling*," so often used in describing poultry, cannot be better illustrated than by referring to a pair of *silver pheasants* belonging to Mr. Lawrence. With a touch more delicate than the finest camel's hair brush is equal to, is each single plume of its feathers marked—clear and distinct as the choicest specimen of the florist's most cherished bloom. Thus gloriously clothed, its crest of crimson velvet, confirms our belief that of all the feathered race none can boast of greater symmetry of form, or a more striking combination of colours in its apparel. In courage, also, it takes no second place to the game fowl itself, and thus strict seclusion becomes necessary where more than one male of these birds are kept in aviaries however extensive.

Mr. Lawrence's stock, like some of his neighbours, has of late rapidly decreased, so many, both of this neighbourhood and elsewhere, being desirous of possessing stock selected with so much judgment. To those who think favourably of Cochin-Chinas, it is satisfactory to hear that the experienced owner of so many varieties of fowls has it in contemplation henceforward to limit his attention to Cochin-Chinas and Spanish; and wherever facilities exist for keeping them distinct, his example is, doubtless, worthy of imitation.

Mr. W. C. Pennington also has a portion of this garden, where we saw some good Spanish and grey Dorkings, principally, we believe, from the stock of Mr. Lawrence. These, though as yet young, may still do much before Christmas next, and heartily do we wish success to Mr. Pennington, who, from the first formation of the Penzance Society, has given it his best assistance in every way. His pen of *golden pheasants* at our last exhibition will long be remembered, and most deservedly were they then distinguished by a medal. Mr. Pennington had also purchased some of the best specimens of *Malays* that were shown at Birmingham, but an unfortunate catastrophe occurred, and they are no longer in existence. An aviary of bright-plumaged canaries shows that Mr. Pennington's partiality for the objects of natural history is not limited to poultry alone.

We are all aware of the indefatigable zeal and industry by which so perfect a collection of *British* birds has been formed by Mr. Rodd. The peculiar character of our district has probably afforded greater facilities for such a work than any other part of England would have given, and the Scilly Islands have also contributed many rare specimens. But, however interesting a task to enumerate the various treasures that have been here accumulated, our present task is with the living, for Mr. Rodd's patronage has been shared by them as well as by the fortunate occupants of his glass cases. Some white Dorkings, which, passing into other hands, won a first prize at the Penzance Exhibition, were the first inhabitants of his poultry-yard, but their plumage was better suited to a rural than a town abode; they were therefore succeeded by grey Dorkings, birds that fully bore out the reputation of Mr. Baily, the

dealer from whom they were obtained. Mr. Rodd is also in possession of some very handsome game fowls, whose martial carriage is, probably, a true criterion of the courage they would manifest were the barbarisms of other days ever likely to be renewed. The Penzance Poultry Society has been greatly indebted to this gentleman for the continued assistance which, as Secretary, he has always bestowed upon it.

(To be continued.)

W.

SUFFOLK HEATHS.

I CAN scarcely conceive a greater treat for the lover of nature than a ride or walk over one of our Suffolk Heaths in the month of June, when the Furze or Whin is in full blossom. These heaths extend along the coast, with slight interruptions, from near my residence for upwards of thirty miles. In some places, as far as the eye can reach, scarcely is anything to be seen but Whins with their yellow flowers waving like a sea of gold. They vary in height from two to eight feet; and a person no sooner enters amongst them, than he is struck with the beauty and variety of their fantastic forms. There is hardly any ornament or order in architecture which cannot be recognized; domes, columns, pyramids, broken arches, &c., all gilded, appear to be scattered around, like the ruins of some ancient city. There is one narrow gorge in particular, about a-mile-and-a-half in length, and where no two persons can well pass, up which I often ride, literally buried in flowers, the sprays being above my head. Their perfume is that of the cocoa-nut. These wild and beautiful places were much resorted to formerly by smugglers, who there secreted their booty. If a run of spirits or tobacco was landed and found its way into these heaths all chance of discovery vanished. "There were three gangs of smugglers here," said an old shepherd to me the other day; "I knew all the fellows well; and often have I driven my flock of sheep to and fro in the early morning over the wheel-marks of the previous night to obliterate their traces, and my reward for this service was a bottle of brandy." Smuggling is not so much carried on now.

Whins are largely used for fuel, fencing, and draining. The parishioners in our parish have a right to cut Whins at pleasure; and the farmers who reside near the heaths have the liberty of using them by virtue of their occupations. The latter employ a labourer, to whom they give 1s. per load of forty faggots for cutting and binding; the load sells for 3s. on the spot to the carters, who retail them round the neighbourhood at 4s. a load. Fires sometimes occur on the heaths, and then the church-bell is rung, and all who can repair to the spot provided with various missiles to extinguish it; when this is accomplished, men are left to watch, for the smothered flame will often break out afresh and run in different directions. Acres of Whins are by this means sometimes consumed, and a bright greensward springs up in their place. Notwithstanding their great annual consumption, Whins are still on the increase.

There are two sorts with us, the *Ulex Europæus*, which blossoms in the months of May, June, and July; and the *Ulex nana*, or Dwarf Furze, which blossoms in September, October, and November. Between these periods, the purple *Ericas*, or Heaths, come into flower, and form, with the Hawkweeds and Harebells, an interesting link in the floral chain. Thus Nature, on the wild heaths, crowns barrenness with beauty. Among the *Ericas* grow the *Ferns*, and both together cover large tracts; they are principally used as litter for farm-yards and cattle-sheds, and tread down into excellent manure. Partridges nestle in the *Ferns*, hatching there their young broods; and for this reason they are mostly preserved. *Lichens* and *Mosses* furnish a varied and elastic carpet. Crabbe, of whom Byron has said that he was "Nature's sternest painter, but the best," has given us in his Poems many faithful pictures of our Suffolk coast; he writes:—

"I loved to walk where none had walked before,
About the rocks that ran along the shore;
Or far beyond the sight of men to stray,
And take my pleasure when I lost my way;
For then 't was mine to trace the hilly heath,
And all the mossy moor that lies beneath:
Here had I favourite stations, where I stood
And heard the murmurs of the ocean-flood,

With not a sound beside, except when flew
Aloft the Lapwing, or the gray curlew,
Who with wild notes my fancied power defied,
And mocked the dreams of solitary pride."

The farms on the outskirts of the heaths have mostly a right of pasturage attached to them, and their occupiers are generally flock-masters, and keep from five to twenty and more score of sheep. It is a beautiful sight to see these flocks approach their feeding-grounds from different points, and separate into lines among the furze bushes, looking at a distance like so many net-works of silver. A shepherd and dog attends each. The latter is shaggy, large, and docile, very useful in keeping the flock apart, very expert in singling out intruders, and he will collect the sheep together, and follow his master wherever he may incline to lead them.

Shepherds themselves are generally morose and taciturn, they are also long-sighted, as is the case with sailors, and most persons accustomed to view distant objects. I remember, a few years since, when some North American Indians were on a visit at Plashet House, the residence of the late Elizabeth Fry, of Upton, they descried minutely objects in the rigging of the vessels passing up and down the Thames, when no other persons present could discern them, and it was not till a telescope had been procured that the facts could be verified.

Hares are not numerous, but rabbits abound, and do much damage to the crops of the farmer; indeed, so rapid is their increase, that it is necessary to have occasional battues to destroy them. They usually sell from 1s. to 1s. 2d. per couple. A pair of these in "a ship-pie" is a welcome treat after a walk on a frosty morning. By virtue of the game laws, game is preserved on our heaths, greatly to the annoyance of the public, to the injury of the agriculturist, and to the demoralisation of the labouring classes. Hawks are often shot or entrapped by the game-keepers. Rooks and starlings frequent in flocks the more open tracts, to feed on worms, insects, and larvæ; they mix with the sheep, probably because the tread of the latter disturbs what they are searching for; but should a crow make his appearance, the shepherd becomes alarmed, as he thinks that this bird portends death or disease among his flock; certain it is that during the lambing season, he is sure to be hovering about. Lapwings congregate in numbers, but a single pair will often separate from the rest to hatch their young at a distance, and should a stranger approach their haunt they will sail around him, and greet him with their wild cries. Plovers, redwings, and fieldfares, are to be met with. The fern-owl or goat-sucker, frequents the hedge-rows; cuckoos, in the spring, are calling to each other throughout the day, and larks are abundant, often damaging the young corn by drawing up the blades and feeding on the sprouted kernels. There is no lack of the smaller birds, as stonechats, whinchats, yellowhammers, greater and lesser redpoles, greenfinches, goldfinches, &c. Our village boys capture these by means of a bird-lime which they make by chewing the bark of the holly-tree.

The configuration of our heaths is undulating; the soil, sand and gravel; and there are abundant evidences of their having once formed the bed of the ocean. The history of the gravel is a desideratum. Its colour, for the most part, is red, and abounding with flints, which are small and rounded, showing them to have been waterworn. Where in the world so many flints could have come from, is a puzzle yet to be solved; certainly not from the beds of chalk in our neighbourhood, for these are free from them. The belief that they were originally marine vegetables seems probable, not only from their exterior form, but also from their interior structure—numbers, if broken, display the stem, branches, and organised parts of plants in great perfection, and sometimes the plant itself will separate entire from its matrix. A diligent and scientific investigator might soon collect a series of these fossil plants, and perhaps be able to name and classify them. And if to the study of these he would add that of the various rounded fragments of rocks, and could decide on their original habitat, he would go far to establish the laws of tides and currents. The veins and markings in many of the red flints, prove that the colouring-matter must have entered them when they were in a pulpy state; these flints, if polished, often vie in beauty with more costly gems. The sifting of stones from

the gravel is the work of our unemployed poor; and the materials thus raised are used for the repair of the public roads. Gryphites, echinites, belemnites, madrepores, coals, &c., are found in the gravel. The sands vary in colour and texture. Bog-earth is found in the water-courses and round the margins of ponds; and the most interesting, if not the most useful strata of all, is the crag, which lies under the gravels, at various depths, being of different thicknesses, and often cropping out on the surface. This is a shell deposit, formed, apparently, at two distinct periods, and consists of the upper, or red crag, and the lower, or coralline crag. On entering a crag-pit (which is generally formed by cutting down a foot of a hill) you have before you a perpendicular wall from ten to fifteen feet high, bristling all over with the projecting points of shells; and here an Owen, or an Agassiz, might dive and delve to his heart's content. It furnishes amusement for the visitor, specimens for the collector, and matter for the scientific inquirer. About four hundred species and varieties of these fossil shells have been already discovered. My own collection consists of about that number, besides a great variety of other organic remains, as corals, zoophytes, foraminifera, teeth, &c., all of marine origin. The shells vary in size from a pin's-head to that of a pony's hoof; and the teeth, from a barleycorn to that of a man's hand. In addition to these, there are occasionally to be met with the teeth of the elephant, rhinoceros, and bear; and it is a curious fact, that out of every hundred of the marine fossils, sixty of them are now extinct, or their representatives are to be found only in tropical seas. The corals must have been produced under a like temperature; thus proving that, at the time of their formation, a totally different order of things prevailed. What secrets, then, does this single drawer in the geological cabinet unfold to us? It is a page in nature, written in physical characters on the earth's changes, itself not being obliterated by time. A careful investigation of these phenomena, and a comparison of extinct with living species, would serve to correct theory, and enlarge the bounds of our scientific knowledge.

S. P., *Rushmere.*

SPANISH *v.* SHANGHAE FOWLS AND GOLDEN PHEASANTS.

THOUGH my experience did not lead me to the conclusion to which you had arrived, viz., "That two or three fowls by themselves will consume proportionately more food in a day than when a great number are fed together;" yet, "as fair play is a jewel," and as you considered this an objection to the fairness of my trial, I have lost no time in putting the things to the test, and the results which I now enclose you, prove that your's is theory and nothing more. You will see, that in confinement the fowls eat rather less than when with a free range; and I think this is natural enough, as in confinement they are not as healthy as when they are able to find insects, and grasses, which they know assist digestion, and promote health. The Gold Pheasants were in the moult, and did not lay.

As for your second objection, I certainly did not weigh all mine, nor can I send you the weights of the "full grown" fowls, but I know that the weight of the Spanish Cockerels I quoted, varied from 5lb. 14oz. to 6lb. 3oz.; with the Pullets just under 5lbs., which even, with the argument lately adopted "in proportion to size," will give a greater weight than that of the fowls on which your trials were made, the average weight of which, I find to have been 3lbs. 9oz. Many of your's must, therefore, be *mere chickens*, at least according to the weight of my Spanish chickens.

I cannot end this discussion better than by quoting a letter from a friend of mine (a man of strict veracity), written from Devonshire, where the fowls do not probably enjoy the over "keen appetites bestowed upon their brethren in the north," relative to a Cochinchina Cockerel, hatched March 3rd; and mind, this is the opinion of a former C. China fancier.

"Fine fellow as he is, however, he certainly does eat enormously. One day I weighed his food, which was chiefly barley-meal mixed with milk and water, of which he

ate in one day about $1\frac{1}{2}$ lb., or to about the value of $1\frac{1}{4}$ d., which I think quite enough "in proportion to size."

I give you these facts; I think they require no comments.

GALLUS.

TRIAL OF COST OF SPANISH AND GOLD PHEASANT FOWLS.

Time of Experiment—Oct. 28 to Nov. 4.

Lots	Description	Age	Weight Oct. 28	Weight Nov. 4	Quantity of food consumed		Cost	Weekly average	No. of eggs	Weight of eggs
					lb. oz.	d.				
1	Gold Pheasant Cock	1851	Not weighed.	Not weighed.	Corn	3 0	3	1½		
	Gold Pheasant Hen	1851			Meal	13	1			
	Gold Pheasant Hen	1851			Bran	1 0	4			
					4 13	4½				
2	Spanish Cock	1850	Not weighed.	Not weighed.	Corn	3 8	3½	1½	6	18½
	Spanish Hen	1851			Meal	1 3	1½			
	Spanish Hen	1851			Bran	1 0	8			
					5 11	5½				

[We are glad that "Gallus" has settled the question, that a few poultry do not eat more in proportion than when many are fed together, because, though our limited experience on this point seemed to indicate the contrary, yet we have never tried the experiment so accurately as has been done by our correspondent. He has proved also, by his experiments, that a Spanish Cockerel, weighing on an average 6lbs, and two Spanish Pullets, weighing rather less than 5lbs. a-piece, can be kept for seven or eight farthings per week each; whilst a Shanghae Cock, weighing 10lbs., and two hens, weighing 7lbs. (we speak within their actual weight), cost each from fourteen to fifteen farthings. We should not be far out, we believe, if we stated that the experiments of "Gallus" demonstrate that Spanish fowls, weighing half as much as Shanghae fowls, only eat half as much food, whilst they lay as many eggs, and one-third larger. Those, therefore, who look to eggs only, will do well to keep Spanish fowls. Those who are limited in the space they can devote to Poultry; those who must have birds that cannot fly over a low fence; those who wish for eggs during the winter, and for chickens for the table when only twelve weeks old, and for full-grown fowls that will fill a dish like a turkey; those who admire gentleness of habit, elegance of form, and beauty of colour; and who would have no objection, as did Mr. Sturgeon, to sell 172 birds for £608, will keep Shanghaes. The result of that sale gives the verdict of the public without requiring a jury to be impanelled.—Ed. C. G.]

THE BEST FUCHSIAS.

ALLOW me to recommend a few of the best Fuchsias to the notice of your readers, and in doing so I would state what I consider the properties of a good Fuchsia.

First, the *tube* should be stout, and in due proportion to the breadth and length of the *sepals*, which should be broad, retaining their breadth for at least half the length, well reflexed, but not turning round like a ram's-horn, but standing boldly out, and the tip turning up with a gentle curve; the *corolla* should expand well, so as to form a bell-shape, and be quite even on the edge.

The following varieties, taking all points, come nearer that standard than any others I know. For *dark varieties* take *Nil Desperandum*, *Champion of England*, *Mayle's Game Boy*, and *Turner's Standard*; these, if well managed, are not to be beaten by anything yet out. For *light varieties*, *Bank's Expansion* and *Princess*, and *Kendal's Beauty Supreme*. I know of no Fuchsia, light or dark, having a tube or corolla to equal this. It is rather bad to manage, it requires a light soil, not much manure, and a little heat to bring the sepals up. *Mayle's Bride* also requires a light soil. *Mayle's Diadem of Flora* is a fine greenhouse flower, but rather too coarse for exhibition purposes; every cottage gardener should grow it. Mr. Harrison, of Darlington, has a first-rate light one called *England's Glory*, if cut blooms form any criterion, and I think they are, any one may purchase this without fear of being disappointed.

Any one who may purchase the above-named, and grow them well, will not regret the advice given by

A LANCASHIRE FUCHSIA GROWER.

BRITISH SONG BIRDS.

THE TITLARK, OR TREE PIPIT.

INSESSORES DENTIROSTRES. ANTHIDÆ.

Alauda trivialis, Pipit Lark; *Alauda minor*, Tree Pipit; *Anthus minor*, Field Titling; *Anthus arboreus*, Tree Pipit; the Titlark.

THE Tree Pipit appears to be not so generally known as to be readily distinguished by unpractised eyes from its congener, the Meadow Pipit, while the two are often confounded with each other, each being called the Titlark. The Tree Pipit, however, which is the true Titlark (that is, if you were to request a bird-catcher to send you a Titlark, he would, on receiving such order, send the Tree Pipit), is a summer visitor, one of our migratory birds, arriving here about the first fortnight in April, and is instantly known by its constant, never varying, but cheerful song, which it commences immediately on its arrival. It is usual to observe it perched on the topmost branch of the highest trees, when every few minutes it uprises into the air some distance, uttering a pretty twittering note till it arrives at a certain height, then, with outspread wings and tail, it gradually descends singing its strain, as much like those of a canary as it is possible for one bird to sing like that of another; this in a few minutes is repeated, in like manner ascending and descending, and by a careful observer may be noticed every five minutes, or even more frequently. Now, the bird with which it is often confounded seldom or never perches on trees, and as for its song, I can say very little in its favour. It may be distinguished from the Meadow Pipit, also, first from its being of a lighter colour in its plumage, not so green a cast; next, in being a larger bird; and, lastly, from its hind claw being shorter, and for that reason better enabled to grasp the branch on which it perches. Its gait, too, is more stately than the Meadow Pipit, it walks along the grass more slowly, and moves its tail in a similar manner to the Wagtails, while it differs from the Larks in being a *washer*, and not a *duster*; though in washing itself, it does not perform this operation so vigorously as other birds, but cautiously sprinkles itself with the water. In its habits it is solitary, only to be seen in pairs.

In its natural or wild state, the food of the Titlark mainly consists of insects, such as beetles, grasshoppers, flies, and their larva, and worms. It may be readily and easily kept in confinement. I have, however, never attempted to keep a wild caught bird, as I so much prefer to bring them up from the nest, they then become exceedingly tame and familiar, feeding from the hand most readily and pleasingly. The food upon which I bring them up is bread and milk boiled together, and formed into a stiff paste, with which some coarsely powdered hempseed has been well mixed; chopped egg, white and yolk together, and crumb of bread mixed together or separate, and when able to feed themselves, they usually partook of the food common to all. If placed in an open aviary their habits are well developed, and they may be seen singing on the topmost branch of a tree or perch, and occasionally from thence catching insects on the wing. Its nest may generally be found on the ground, always well concealed, and formed of such materials as best corresponds with the spot selected, but is usually composed of dried grasses and fibrous roots, lined with similar materials of a finer quality, and mixed with hair. The female is a close sitter, and is not readily frightened from her home; but if

she once catches sight of your eye watching her, she stealthily and quietly creeps off her nest, and running along the ground some distance, at length takes to flight. The male bird is usually singing on a tree very close to the nest, which I have often discovered by observing the male bird, after singing, descend to visit his mate. They will breed in confinement, which has been the case with me; this I attribute to my having brought the birds up by hand.—
WILLIAM RAYNER.

DISEASES OF POULTRY.—LAYING SOFT EGGS.

SOME time since I noticed in your paper a request for any information respecting the Diseases of Poultry, and their treatment. For some years I have relinquished the use of the lancet for that of the pen, but when opportunity offers I employ my medical experience (now getting somewhat rusty for want of use) in alleviating the disorders of my domestic pets. I need scarcely say, that all empirical remedies, such as Rue-pills, &c., &c., meet with no encouragement from me; but that I endeavour to treat any disease on ordinary general principles. My medical experience with regard to Poultry is rather limited, my stock consisting of the progeny of two hens, and a cock of Baily's grey Dorkings, which I have found to be as hardy and healthy as it is possible for fowls to be; I have not lost this year a single chicken, although some of the breeders of Cochins in the immediate neighbourhood lost scores of their birds. The only disorder that I had to treat was the laying of soft and partly-formed eggs, which occurred in one Dorking hen, and in a half-bred Cochin. It appears to me that the laying of soft eggs must arise from one of two causes; either a deficiency of lime rubbish, or old mortar, for the fowls to peck at, which was not my case; or from an excited or inflamed state of the oviduct. Thus a hen escaping into the street, and being driven, will often lay a soft egg or two. The Dorking hen above alluded to began to lay exactly one month after hatching, and laid very large eggs, some weighing more than 3½ oz.; she then laid several soft eggs when at roost, and others of which the skins were not closed; the feathers over the back were raised; there was great effort made to get rid of the imperfect eggs and general feverishness; all the symptoms betokened inflammation of the egg-passages, and the treatment was evident. I employed the same remedies that would be used to subdue inflammation of the mucous membranes in the human subject,—one grain of Calomel, and one-twelfth of a grain of Tartar emetic, were made into a pill with bread-crumbs, and readily taken. The next day no egg was laid; but on the following day a well-formed hard-shelled egg. Some weeks or months after the complaint recurred, was met by the same treatment, and a hard egg was again laid on the second day. The half-bred Cochin hen was treated in the same way, and with precisely the same result.

There ends my poultry medical experience. Should I at any time have any extension of practice, or any *post mortems*, I will, if you think my notes worth inserting, send you the result.

As I have the pen in hand, I may perhaps be allowed to give you *my* opinion respecting the Cochin controversy. As *fancy* birds I admire them; those sold at Baker-street from Mr. Sturgeon's stock were truly magnificent. As table birds, it appears to be very doubtful whether (notwithstanding their great size when full grown) they can be fattened to eight or nine pounds at four or five months, like the Dorkings. Again, their fat and flesh come in the wrong place; their wings are so imperfectly developed that they do not fly; and the muscles which move the wings, and form the mass of flesh on the breast, are slightly developed also. Then, although "*de gustibus non est disputandum*," I doubt very much the delicacy of that palate that prefers a Cochin to a Dorking. As to eggs; the fact that the hens become broody several times during the season must lessen their productiveness below that of the Dutch every-day-layers, who never sit; and it appears to me, that if an equal number and weight of eggs can be obtained from a Cochin and a Hamburg, the latter must be the most profitable; for the larger bird must require a larger amount of food, to

supply the function of nutrition and the production of animal warmth.

Another point, and I will finish this rambling, desultory letter. Will you lend your aid to securing uniformity in the names of the Polish and Hamburg. Baily, in the new edition of his book on Fowls (which, by-the-by, is one of the very best really practical books I have seen), Trotter, Dixon, and Richardson, all agree in terming *all* the top-knots, "Polands," whether they have small combs or not, and they confine the term "Hamburgs" to the Dutch every-day layers and its varieties, which are all without a top knot. If this example is followed, there will be a uniformity of nomenclature, which I was sorry to see one of your recent correspondents endeavoured to overset. It appears to me, that it would add much to your usefulness, if those desirous of exchanging cocks, to prevent breeding in-and-in, were to communicate to you; and, if you permit such a notice, I would say that I should be glad to exchange one or two very promising grey Dorking cockerels for equally good birds, or for either gold or silver-spangled Hamburgs.—W. B. TEGTMEIER, *Tottenham, Middlesex.*

TO CORRESPONDENTS.

* * We request that no one will write to the departmental writers of THE COTTAGE GARDENER. It gives them unjustifiable trouble and expense. All communications should be addressed "*To the Editor of the Cottage Gardener, 2, Amen Corner, Paternoster Row, London.*"

TO ALL CORRESPONDENTS.—In self-defence we are reluctantly compelled to announce that we must decline inserting any announcements of articles to be sold, or required, except as advertisements. We are compelled to adopt this resolution, because we find that a contrary course is misinterpreted, lays us open to the charge of giving preferences, and has led to impositions, not only upon ourselves, but upon our readers. Our resolution is sustained by the following letter, by which we are much obliged:—"Enclosed you have payment for inserting the advertisement herein. Should this not be correct, please let me hear from you. You will, I have no doubt (when I tell you that myself and other gentlemen, your constant readers and well-wishers coincide with me), understand me when I tell you, with the very best intentions and most friendly feeling, that you do not get the support to nearly the extent you would do from gentlemen having a few "spare Cochin-Chinas," &c., to dispose of—(a numerous body now)—in consequence of allowing any one who writes to you to append to his communications an advertisement of this or that sort of fowl, or a few 'Spanish' to be disposed of, &c. In one case an advertisement appeared in the regular character, and on the same page, three or four communications of this very nature, and each appearing in the very article before put before the public. It has been thought that this favour was only allowed to correspondents who were also subscribers, or well known to the editor. But this is not so; in one case, at least, when fowls were purchased from one of these favoured ones, and the purchaser was most shamefully cheated and imposed upon; whereas, not unlikely, the honest advertiser came off without a sale, and minus the money sent for his more expensive, but less favoured, advertisement. It strikes everyone so clearly that this is not the kind of way an honest advertiser should be treated, that I am sure I have only to name this to secure better treatment in future. In conclusion, I wish you every success, and hope, in future, I shall see 'The Country Gentleman's Companion' increases in circulation, and made a medium for advertising to the extent its editor's most sanguine desires can wish." We now state most distinctly and unreservedly, that when we have allowed such notices to appear, it has only been on some plea which we thought called upon us to sacrifice our own pecuniary interest. In future we must be more firm—for the sake of others as well as of ourselves.

SILK FOWLS (*H. S. B.*).—There may be a variety of these in Cochin China; but they have no relationship to the Shanghai fowl. The Silk fowl is a native of the warmer parts of the East Indies. We never heard of a cross between them and the Shanghai fowls.

PINETUM.—*Ignotus* has the following—*Cupressus stricta*, *C. Gonioides*, *C. macrocarpa*, *C. funebris*, *Araucaria imbricata*, *Juniperus communis*, *J. Chinensis*, *J. excelsa*, a deciduous *Cypress*, *Cedar of Lebanon*, *Pinus excelsa*, *P. insignis*, *Cryptomeria Japonica*, *Taxodium sempervirens*, *Abies Canadensis*, *A. Douglasii*, *A. Menziesii*, and wants a few more of the *Abies* tribe, or other *fastigiata* evergreens. A few more desirable additions to your list are—*Abies morinda*, alias *Smithiana*, or *Khutrow*, for the three are the same. Then the Silver-fir tribe, or *Picea*, as *P. Cephalonica*, *P. Fraseri*, *P. Webbiana*, and *P. Pinsappo*. The old Silver-fir is as handsome as any; and, where the soil suits it, the Balm-of-Gilead-fir, or *P. balsamea*, the same. *Pinus pinea*, or Stone-pine, *P. Sabiniensis*, and *P. Lambertiana*; *Cupressus torulosa* and *C. Uhdiana*; and of the very newest, if you can spare a guinea for it, *Fitzroya Patagonica*—a fast-growing and beautiful tree, after the manner of the *Cypress*. Of *Junipers*, plant *oxycedrus* and *thurifera*. The Virginian *Cedar* (*Juniperus Virginiana*), and Chinese *Arbor vite*, are not in your list; neither are the *Deodar* and *Mount Atlas Cedars*, all of which should be in every selection of the order.

HINTS AND ANNUALS (*S. S.*).—We quite agree with you that it would be desirable to have monthly lists of Annuals and other things

that might be sown in heat or cold, and now that we have more room we shall keep your "hints" in mind. Nothing of this sort, however, will be in season before the middle of next February. Meantime we should like to hear of any other "hints" which our subscribers think would improve our pages. One of our chief recommendations has been to fill all the spare places between bedders as soon as the beds are planted; but whether "one sort, or colour, should be planted in each bed" is a matter of taste with which we never interfere. We prefer three colours in some of the beds, two in others, and one only in the greatest number. At other times, the stock of Annuals governs our choice; the truth is, we can hardly do amiss if the soil is all covered as soon as possible. It is out of our power to say at what distance bedding-plants should be planted, for each kind cannot be persuaded to be of the same size all over the kingdom at the time of planting. We have planted *Verbena* at six inches apart; *Calceolarias* and *Petunias* the same; *Geraniums* from nine inches to a foot from plant to plant, and so on; but all these we have put in at twice or three times such distances. The *Kilkenny Anemones* are the same as the common border ones all over the kingdom.

BACK GARDENS (Grumbler).—Mr. Robson will tell you how to make the best of the back garden, 200 feet long and from 35 to 40 feet wide. We shall also give a plan or two to convert such enclosures into flower-gardens; still we have no sympathy with "grumblers."

CATERPILLARS ON HAMBURGH GRAPES (C. W.).—"The Caterpillar which feeds on the outer skins of the berries of Grapes is that of the little moth *Cochylis Amphaciella* of Andouin's 'Memoir on the Insects of the Vine.' Fumigation and a sharp look out seem to be the only serviceable remedies."—J. O. W.

OXALIS BOWENI (M. D. P.).—We suspect the dull weather has lately been against the flowers expanding. Give it the openest and lightest position you can command, and a temperature little below 50° at night. See an article to-day by Mr. Fish.

POULTRY-KEEPING.—A *Poor Man's Well-wisher* writes thus:—"When will this question be set at rest concerning which is the most profitable breed of poultry for a poor man? I cannot wait any longer, for have a pair of some sort I must; for what I have read about them in THE COTTAGE GARDENER has put me so much agog for some of these fine birds, that I can hardly sleep in my bed for thinking about them. What profitable things they must be to live upon little more than a penny per week, and to lay six eggs in a week that are worth one shilling each! O dear me! but I must have some of them, you may depend upon it. If I was not a poor man, there would be Cochins-Chinas, Dorkings, Spanish, and Malays, to be seen at my house in less than a month; but, as it is, I am hardly able to purchase one pair, and this makes me so desirous of knowing which would be the best; but I think I may make myself quite satisfied that there is no one going to tell me, so I must purchase one pair at a time, and prove for myself. I think I shall commence with the Cochins-Chinas, for I have a friend that has reared five this summer, two cockerels and three pullets. They were hatched the last week in May, and he tells me that the five have not cost him twopenny per week; and I am sure they have not been within half-a-mile of a stack-yard, or a barn-door, neither have they seen a field of grain of any sort. What will Mr. "Gallus" say to this? They have a good walk on grass, and they are now living, and have been for this last month, upon acorns, which they pick themselves; and when they come home at night they would not thank you for a bit of barley, although Mr. "Gallus" says they are never satisfied. Now all this I know; but about Dorkings, Spanish, and Malays I know nothing; but I don't care how soon I do, for I long to be in possession of some of these profitable birds. But my wife is quite angry to think about me giving a guinea for a pair of fowls, when I have to work hard all the week for the one-half of it; for I must inform you that I am nothing but a poor day labourer, and gold is a thing that I see but once a fortnight; and besides, I shall have to pay for every grain that they eat, for I have nowhere to turn them out, neither on grass nor gravel; but it is no use, for this whim has got hold of me so fast that I must have some of them. But woe-betide you, Mr. Editor, and Mrs. Anster Bonn, if I do not find some little truth in your writing, for I know my wife will comb my hair for me if I do not get some little profit, after spending so much money. So now I hope, instead of telling me which is the best sort to keep, you will tell me which is the best and cheapest way of feeding them, and tell your readers to follow my plan, and get a pair of each sort, keep them separate, and judge for themselves which they think are the most profitable; or, if they do not like to venture into quite so deep a water that I am venturing into, why all that I can say is, there is a good time a coming, so they must wait a little longer till I am got safe ashore, and then I will tell them exactly the way that I got over, if ever I do get over at all, and if I sink I will hold up my hand; but the worst of it will be to them, if there is sound land on the other side, I shall be a mile-and-a-half ahead of them, for you may depend upon it if they waited to see me safe over I shall not wait for them afterwards, for I shall be boldly on the road, for I know very well that there will be poultry shows in our country shortly, where prizes will be given for the best breeds of poultry, and then how I shall laugh at them if, the whilst they are dabbling in the matter, I am in the field gaining the prize. But I must stop, for I dare say you will not think this lot of stuff worth a place in THE COTTAGE GARDENER; but, Sir, I hope you will encourage your cottage readers to press forward. I will tell them anything that I know with the greatest of pleasure, if they would like to hear it, and you have no objections against printing it; there is always something to be learned of the ignorant."—A POOR MAN'S WELL-WISHER. [We shall readily insert more of your "ignorance."—ED. C. G.]

MASTERS AND THEIR GARDENERS.—We well knew when we inserted "A City Friar's" letter, that he had run his pen into a hornet's nest. We have received many replies, but can find space but for one, and with this the discussion must cease:—"I hope you will pardon the liberty I have taken in writing a few lines to you on the subject of a gentleman's letter, who styles himself 'A City Friar,' in your number of October 14. He considers gardeners as 'droll dogs,' and as having the bump of conceit. Now, it is all very well for the masters, such as 'The City Friar,' to be

talking like that; but what would be the consequence if they were to listen to all that is told them? They would be led astray and blamed for carelessness, or for want of a little more of 'the bump of conceit.' If a master wishes to be as master, let him be one, and let the gardener be a gardener; or, else let the master have a common labourer, and himself may be the head-gardener. There are a class of people who are very conceited—masters as well as servants; but you will not find there gardeners who understand their business. They know what wants doing as well (in my opinion, better) than their masters. There are many things a gardener can see want doing that a master does not see, and it grieves him because he cannot do it; why is this but because there are other things that want doing at the same time? This I know by experience; and my opinion is, that if such masters as these were to allow more strength, and leave the managing to the gardener, their gardens would be kept in better order, and things that the master sees undone would be done, and it would be more to the master's interest as well as the gardener's credit. It makes a man careless when a master comes ordering a thing one way, and, perhaps, that thing ought to be done diametrically another way. They would find it quite a different thing if they could but exchange situations."—A CONSTANT READER.

CELERY (J. R. K.).—Nutt's *Champion* and Cole's *Solid-Stalked* are the best varieties we have grown; but we see that at the last meeting of the Horticultural Society, in Regent-street, *Whittington's Red* carried off the prize. Let us add, however, that Celery is so much influenced by cultivation, that almost every variety can be grown to a very large size and to a high degree of excellence; rapid unchecked growth secures both those good qualities. We cannot name dealers.

OUR VOLUMES (Clericus).—You can have the two half-yearly volumes about bound together in one volume, with the fitting Indexes, by applying at our office. We are enquiring about the seed, and will send it if we succeed; we have none left.

SEWAGE FROM HOUSE AND STABLE (E. C. S., Beccles).—Probably about four buckets of water to one of the liquor will make it sufficiently weak for both fruit-trees and flowers; but this is not the time to apply it to them. Why not give it to *growing* kitchen-garden crops, such as cabbages, celery, &c.

DRAIN FROM STABLE (B. J.).—To convey the drainage from this, the piggery, &c., to a tank, nothing will answer better than the sewer pipes now made of coarse stoneware. If they are not less than six inches diameter they will not be liable to choke, if laid with a moderate slope to the tank. A common cast-iron pump is the best for emptying the tank.

HEATING SMALL CONSERVATORY (E. C.).—As your conservatory does not contain more than twenty-five cubic yards of air, and you only wish to exclude the frost, we should have two four-gallon stone bottles, and if one of these was kept with hot water in it during the day, and both were kept so filled at night in the conservatory, you would effect your purpose. To prevent their appearing unsightly during the day, it is very easy to have a wooden case perforated with holes to put over them.

SHANGHAE FOWLS (A Poultry Fancier).—If you cook the cockerels when three or four months old, accordingly as they have thriven, their legs do not appear awkwardly long when roasted. Nor do they at any time appear too long, in proportion to their size, if true and well-bred specimens are kept. It is a libel to call the gangling, half-Malay creatures, which are so common, by the aristocratic title of "Shanghae."

TRAINING POTS.—Mr. J. H. Horsley justly observes: "I have often thought what an assistance it would be if we could get some pots made with small holes round the rim to pass the matting through, instead of crooks and all other contrivances. I have written to Mr. Phillips, potter, of Weston-super-Mare, who informs me he will get some pots made immediately for the trade; and I am sure Geranium growers, who are desirous of making good specimens, will find those pots very useful."

LOUISE BONNE PEAR.—Mr. Hogg says:—"It is a very old French variety, and originated about the middle of the 17th century, in Poitou, on the property of a lady whose christian name was Louise, but whose surname I have never been able to discover. There is, I believe, no good ground for calling any other variety by the distinctive name of "Bonne;" but the old Louise Bonne, being for upwards of a century and a half a popular variety in France, other varieties received similar appellations, either from fancied resemblance to the old variety, or as recommendation of excellence, merely distinguishing them with the name of the places where they were raised, or whence they came. The Louise Bonne of Jersey is a misnomer, and has no claim to the 'Bonne.'"

NAMES OF PLANTS (Rev. R. M. E.).—You send us such small specimens, that you give us much needless trouble; why not send larger ones? We cannot say, from such a specimen, which of the *Geraniums* your's is. The variegated leaf is of *Phlox suaveolens*, var. *variegata*. The other small leaf is, probably, of *Swainsonia galegifolia*. We really have not time to ponder over such specimens. (W. X. W.).—Yours is not a *Helichrysum*, but *Helianthus altissimus*.

NAMES OF FRUITS (A. B., an Old Subscriber).—The apple is *Dumelow's Seedling*, and the pear is *Easter Beurre*.

LONDON: Printed by HARRY WOOLDRIDGE, Winchester High-street, in the Parish of Saint Mary Kalendar; and Published by WILLIAM SOMERVILLE ORR, at the Office, No. 2, Amen Corner, in the Parish of Christ Church, City of London.—November 18th, 1852.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last twenty-five years, the average highest and lowest temperatures of these days are 47.1° and 35.5° respectively. The greatest heat, 60°, occurred on the 28th in 1828; and the lowest cold, 16°, on the 29th in 1846. During the period 85 days were fine, and on 90 rain fell.

BRITISH WILD FLOWERS.

WATER-LILIES.—NYMPHEACEÆ.

(Continued from page 95.)

NUPHAR. YELLOW WATER-LILY.

GENERIC CHARACTER.—*Calyx* below the seed-vessel, of five or six large, leathery, concave, coloured, permanent leaves. *Petals* numerous, oblong, much smaller than the calyx; furrowed and honey-bearing at the back; proceeding, like the stamens, from the receptacle. *Stamens* very numerous, unconnected with the germen, line-shaped, bent back. *Anthers* line-shaped, of two parallel cells, closely attached to the inner surface of the upper part of each filament. *Germen* nearly stalkless, egg-shaped, with an elongation at the summit. *Style* none. *Stigma* stalkless, orbicular, convex, entire or notched, with many central radiating clefts. *Berry* leathery, smooth, pointed-egg-shaped, of as many cells as there are rays, finally pulpy within. *Seeds* numerous, smooth, egg-shaped, in several rows in each cell.

NUPHAR LUTEA: Common Yellow Water-lily; Water-can; Brandy-bottle.

Description.—It is a perennial. *Leaves* slightly egg-shaped, but nearly round, ten or twelve inches in diameter, floating nearly flat upon the water's surface, the edge only being slightly raised as if to keep the water from the upper surface, and the lobes at the stalk lapping over each other, tough, pliant, nerves or veins much raised beneath, upper surface bright green, but under surface paler; leaf-stalks smooth, three-sided, and their length depending on the depth of the water. Dr. Martyn had them 5½ feet long. *Flowers* an inch and-half in diameter, smelling like wine or

brandy, which, connected with the shape of the seed-vessel, has given occasion for one of its popular names. *Calyx* larger than the corolla, its sepals being almost an inch in diameter, roundish, erect, quite entire, slightly waved, smooth, tough, yellow, except at the base outside, where they are green. *Petals* fleshy, golden yellow, half-an-inch long, notched and grooved, from ten to twenty in number. *Stamens* very numerous, amounting from 100 to 165, pressing closely on the germ when the flower first opens, but falling back after shedding their pollen; filaments yellowish, thicker than the anthers, which are yellow, and two lines in length. *Germen* egg-shaped, blunt, smooth, terminated by a small roundish hollow. *Style* scarcely any, with a stigma yellow, unequally and slightly notched, rather convex, but depressed in the centre, and with eleven or twelve rays. *Seed-vessel* bottle-shaped, smooth, divided into twelve or more cells, and irregularly subdivided, so that each seed seems in its own cell. *Seeds* pointed egg-shaped, smooth, shining, and angularly-keeled. *Flower-stalks* nearly cylindrical, long in proportion to the depth of the water, always elevating the flower above its surface, but after impregnation bending down and ripening the seeds under water.

Nuphar differs from *Nymphaea* in having its petals and stamens inserted into a disk at the base of the germen. In *Nymphaea* the disk adheres to the side of the germen.

Sir J. E. Smith considers there is another species, which he describes as *Nuphar pumila*, or Least Yellow Water-lily, but we think with Willdenow and others, that it is sufficient to consider it only as a variety of *N. lutea*. There is no other distinctive character that we know of, than that the flowers are smaller, the petals paler, and the lobes of the leaves do not over-lap each other.

Places where found.—In slowly-flowing streams and pools; not uncommon.

Time of flowering.—July.

History.—Sir J. E. Smith retained for this genus the name *Nuphar*, given it by Dioscorides, and which name the modern Greeks, who make a cordial of its brandy-perfumed flowers, after the example of their forefathers, have but little corrupted, though the Turks have perverted it into *Nufar*. Withering says that the roots bruised in milk destroy the crickets and cockroaches which partake of it. An infusion of a pound of the fresh root in a gallon of water, and a pint of it taken night and morning, is said by the same authority to have cured a leprous eruption on the arm. The root, leaves, and flowers, are also employed in tanning, so that it must contain much astringent matter, or tannin. Swine eat it; goats are not fond of it; and cows, sheep, and horses, according to Linnaeus, refuse it. He also states that it drives away crickets from a house by its smoke when burnt. (Smith. Martyn. Withering. Baxter.)

It has been lately prominently and repeatedly stated in the columns of one of our older contemporaries, that "plants will, under certain circumstances, grow in the absence of leaves." If our contemporary merely intended that plants will emit fibrous roots, or that deciduous species will put forth leaves and even flowers whilst divested of foliage, he would not have given such prominence to his remarks, for these are phenomena

which we see every year among our newly-moved plants and upon our fruit walls.

It is, therefore, intended to be announced as an important discovery that plants which usually perform their growing processes and increase their solid matters by the aid of their leaves, may, "under certain circumstances," be made to increase that solid matter without leaves. One inference intended to be drawn from this

is, that farmers and gardeners may cut off the leaves of their Turnips, Carrots, and Mangold Wurtzel, or Beet, and whilst using those leaves for fodder, that the roots will go on increasing in size.

Now, we warn our readers, without any reservation, against any such practice. It is quite true that you may cut off the tops or leaves of those root-crops, and they will continue to put forth fresh leaves, and to increase in *bulk*, though more slowly than if the tops were left uninjured; but there will be no increase of *solid* matter. The roots will be more spongy, and contain a greater amount of water, but they will not increase in nutritive constituents. If only a portion of the leaves, and those only which age had rendered inactive, are removed; and if a sufficiency of young leaves are left to continue the elaborative functions, we all know that such treatment improves the vigour of the plant; but such judicious culture, for the better admission of air and light to the crop, is no modern discovery, but is to be found in every gardening book published during the last century. On the other hand, so far is the removal of all, or even nearly all, of the leaves of our root-crops from being of any benefit to them, that you may, by repeating the process, gradually render the roots worthless, and even kill them.

A similar delusion once existed, and perhaps still exists, relative to the Potato. It is well known that old tubers of this buried in sand, and kept in a warm dark place, will often produce a cluster of young tubers, without making any attempt to produce leaves. This fact we have seen quoted in justification of the practice which has been recommended of pulling off the stems of the Potato as soon as they showed symptoms of the murrain; the inference being, that the tubers of the crop would continue to grow without the leaves and stems, as in the other case. Such inference is most erroneous. A tuber buried in sand will produce young tubers, but it is entirely at the expense of its own substance; and so far from increasing in solid constituents, we believe that the old and young tubers actually contain more water and less solid matters than the old tuber before producing the young ones. This is easily tested, and we are of opinion that the results of our experiments will in every case be verified. We have weighed six Potatoes, and then had them sliced, and all the water evaporated from them by long exposure to a heat just below 212°. We have weighed three dozen other Potatoes, of similar size, and buried them in sand until some of them produced young tubers. We sliced six of these, and the young tubers they produced, and, having dried them in a similar manner, found in every instance that they yielded less solid matter, in proportion to their original weight, than the six which had not been allowed to produce young tubers.

We, therefore, repeat the warning to our readers, not to be induced to remove an excessive amount of leaves from their root-crops; and we take the opportunity to extend the warning against any extravagant recommendation which at any time goes the length of proving, if correct, that He who created plants was mistaken in

His plans. If experiments are stated which seem to sustain such a recommendation, be assured, beyond all doubt, that either the experiments or the deductions from them are erroneous. Never mind, though the authority which says that plants will increase in solid matter, "in the absence of leaves," tells you that the contrary opinion is "a deeply-rooted prejudice;" it is a prejudice sustained not only by science but by practice.

FORSYTH MSS.

THE projects of SIR JOHN SINCLAIR for turning the soil of Great Britain to advantage were not confined to farming and gardening, but embraced many other arts, foremost among which was extensive planting. These projects he continued after he lost the Presidentship of the Board of Agriculture, and down to the time of his death.

There is no doubt that his Whig politics were the cause, of his being deprived of the Presidentship, yet notwithstanding the castigation he received from Mr. Pitt, and notwithstanding all the government influence, he only lost the office by a single vote, thirteen voting for Lord Somerville, and twelve for Sir John Sinclair. This was in 1798, and in the year following we find a note from him to Mr. Forsyth, containing the following queries. It is dated from 35, Craven Street, Strand, 10th of December, 1799.

QUESTIONS REGARDING PLANTATIONS.

1. If plantations of 500 acres of waste lands were to be made in different parts of England, what do you imagine would be the average price of the land?
2. What would be the expense of fencing the land against sheep and cattle, if 500 acres were included in one plantation?
3. What would be the expense of planting 500 acres with larch; and for how much per acre could they be planted, and upheld for seven years?
4. What would probably be the value of a plantation of larch of thirty years growth, per tree, and per acre?

We must now conclude our notice of this indefatigable, useful, and benevolent man. No man, says one of his biographers, could devote himself with more ardour and perseverance for the benefit of his country, the support of all public institutions, and the reward of merit wherever found;—for the well-being of mankind was the object nearest his heart. How much his sovereign appreciated his merit is testified by his being created a Baronet in 1786, and by his being made a Privy Councillor in 1810. He died on the 21st of December, 1835, at his house in George Street, Edinburgh, aged 82 years.

COVENT GARDEN.

WHEN we entered upon the preparation of these reports, the only object we had in contemplation was to furnish an account of the state of the London fruit and vegetable markets, and of the different descriptions of produce there offered for sale. But, as we stated last week, various ideas force themselves on our mind as we proceed, and it may not be considered out of place to record them here. One of these, as we remarked in

our former notice, is the extended cultivation of fruit as an article of commerce. It is not, however, our intention to enter fully into a treatise on this subject, in what may be called the usual acceptation of the term, but simply to make a few remarks on opportunities which are afforded on almost every property, however small, for introducing some of the best and most profitable varieties, and employing the space which would otherwise be neglected. As regards the systematic planting of orchards, our able coadjutor in the fruit department has done, and will still continue to do, ample justice to this subject.

It has often occurred to us, in our journeyings through the different counties of England, that the hedge-rows and hedge-row-banks, with which the country is so profusely intersected, instead of being allowed to remain as they are, a mass of tangled brambles and bryony, relieved here and there with a stunted old pollard, might be planted with fruit-trees of such sorts and varieties as would not only be useful for home consumption, but which might produce a considerable revenue to the owner. We do not mean that there should be an universal and indiscriminate system of planting, but that it might be carried out to a certain extent, at least in such situations as the proprietors deem best adapted for the purpose. We have ourselves done so, and find, from experience, that it is a system which may be followed out even to a greater extent than we have practised it. We have even done more, for the approach to the dwelling-house is planted on either side with an avenue of Apples and Pears. The varieties we have chosen for this purpose are, of course, all choice as regards the quality of the fruit; but we have also selected them in reference to the habit of growth of the trees. All the *Apples* are of a round-headed habit, and the *Pears* of a pyramidal habit of growth, and in each row there is an apple and pear alternately. This has now been done some few years, and the trees are all well established. We leave our readers to imagine what effect this has produced: how it looks in spring, the Pears dangling with tassels of the purest white, the Apples decked with clusters of red and white, and pink blossoms, with the "little busy bee" humming from flower to flower; how in autumn, "the pulpy fruit with gold irradiate" delights the eye and pleases the taste; and how in winter they look as well as other trees do. If we are to have trees in our shrubberies, and approaches, and hedge-rows, why should they not be of such a kind as will be of some other use than merely to fill up a blank, form a blind, or afford shelter? If there should be a bad fruit year the loss could not be anything, for if the trees had been Ash, Oak, Elm, or Lime, they would have produced as little, and even less. The expense, then, of such a plantation of fruit trees is nothing except the first outlay. It occupies no space which could be appropriated to any other crop, and it answers all the purposes that would be expected from a plantation of timber-trees. And, by-the-by, speaking of timber-trees, we have in fruit-trees *timber* also; for the wood of both the apple

and the pear is constantly in demand, by turners for the manufacture of toys, and by cabinet-makers for inlaying. It may not be generally known that the blocks used by the floor-cloth manufacturers for printing the designs on the floor-cloth are all made of the wood of the pear-tree, so that even when the trees become old, they may be cut down and appropriated to some useful purpose.

We find our space will be hardly sufficient to enable us to enter upon a consideration of the varieties we would recommend for this description of planting this week; but in our next report we shall furnish lists, with observations. Meanwhile, our readers can be "turning the matter over in their minds," as this is now the best season for planting all sorts of fruit-trees, particularly on light soils, and even on those of medium texture, provided they are well drained, which all soils for fruit-trees should be. We shall now proceed to our more legitimate subject, namely, a notice of what has been doing in Covent Garden during the week. As regards prices we have nothing new to communicate. Both fruits and vegetables continue the same as last week, without any alteration. We must, therefore, refer our readers to our last number.

In *APPLES* we have observed an arrival of the *Royal Russet*, a fine old English variety, and a great favourite in many districts. There is one objection, however, to the russets; they are so liable to shrivel. We have also noticed a considerable supply of the *Summer Pearmain*, also a fine old autumn apple, and from its fine striped skin a great favourite in all markets. It is this variety which is generally, indeed we may almost say always, in nurseries under the name of *Royal Pearmain*, a name which by right belongs to what the Horticultural Society in their Catalogue call the *Herefordshire Pearmain*. The *Summer Pearmain* has also had its name changed, and we must allow with some considerable degree of justice too, to *Autumn Pearmain*, for certainly it is much more of an autumn than a summer variety. *Newtown Pippins*, and *Lady Apples*, are much more plentiful than they were last week; the latter particularly make the fruiterers' windows very gay. We find, however, there is an attempt to delude those who do not know better, by substituting a small flat red apple, similar in size and shape to the Lady Apple, for that variety. Any body, however, who has carefully observed the true variety once will be sure to know it again. Its shaded side is of a fine clear lemon-colour; and that next the sun is of the purest and deepest crimson, the whole shining as if varnished. The light and dark colours do not blend so gradually as in most other sorts, for the skin of this variety is so sensitive that even a twig or the slightest shade of a leaf is indicated. It is, in fact, as sensitive as the silverized plate of the dauguerréotypist; and on the red cheek of the little *Lady Apple* any device may be made by simply fastening the device on the fruit before it has received its full depth of colour. *Ribstones* continue plentiful, and there is generally a good supply of baking varieties.

In *PEARS* we have had some new arrivals, such as *Nelis d'Hiver* and the old *Crasanne*, both very fine des-

sert varieties. The others are *Glout Morceau*, *Duchesse d'Angoulême*, and *Passe Colmar*. *Beurré Diel* has also appeared during the week. Of most of these we shall speak on future occasions.

The CUT FLOWERS consist of *Heliotropes*, *Roses*, *Chrysanthemums*, *Scarlet Geraniums*, *Cinerarias*, *Camellias*, *Double Blue Violets*, *Chinese Primroses*, single and double; there were also some rare specimens in this way, consisting of *Euphorbium jacquiniflora*, *Oncidium lanceanum*, *Passiflora cærulea racemosa*, *Dendrobium spectabile*, and some other rare stove plants. H.

GOSSIP.

THE exhibition days at the *Chiswick Gardens* of the Horticultural Society will be, in 1853, on the 14th of May, 11th of June, and 9th of July.

At page 144 of our fifth volume, when giving an account of the *Stanwick Nectarine*, we thus expressed ourselves:—"The Duke of Northumberland having munificently given buds from this Nectarine to raise trees for sale, the proceeds to be given to the Gardeners' Benevolent Institution; and Mr. Rivers, in a similar good spirit, having raised these trees without charge for their propagation, we have thought it right to place these particulars before our readers; but we do no more. Without expressing our opinion upon the merits of the Nectarine, we sincerely hope that both the Institution and the purchasers of the trees may be one and all benefited." For expressing ourselves so guardedly we were blamed at the time, but we were immovable in our resolution not to recommend the Nectarine until its value in our climate was proved by successful cultivation; and those who blamed us must now "eat humble pie." We are sorry to read the following, whilst we congratulate ourselves that we did not aid in ministering to the disappointment. Mr. Ingram, the Queen's gardener, says, "The Stanwick Nectarine is unfit for planting on the open walls of the kitchen-garden;" and another authority says that, even when under glass, it requires fire-heat, and that in flavour it is not superior to the Elruge.

It is very well known that as long since as the time of the Roman emperors, some transparent stone (*Specularis lapis*) was split into thin panes, and used as a shelter for Cucumbers, &c. There can be no doubt, from the description given of it by Pliny in his Natural History (Book 36, Chapter 22), that this stone was the same as our *Talc*. It has been customary to think that this has been quite superseded for gardening purposes. Such, however, is not the case; and since rough glass has been found superior for plants to that which is perfectly transparent, there is reason to believe that talc for similar purposes may be employed. At all events, it is worthy of a trial, for our contemporary, *The Builder*, says, that it may be supplied considerably cheaper than glass, it is much less liable to breakage, and that being lighter, the frames of houses and pits may be less stout. It is added, "Talc has been tried in several places, and found to answer." If any of our

readers have tried it, they will much oblige us by stating the results of their experience.

We have been asked by a correspondent (*Norwich*) whether "soil and temperature" have any influence in rendering one English county less capable of producing *Cheese* than another county more celebrated? and we have no hesitation in saying, that in such cases we believe that soil and temperature have nothing to do with the result. We are quite aware of the old satirical story of the rats eating the millstones and leaving the Suffolk cheeses, yet we are quite of opinion that, with equal dairy skill, and equal richness of pasture, as good cheeses could be made in the east as in the west of England. In confirmation of our opinion, we quote the following from the *Preston Guardian*:—

"So many exaggerated statements have appeared in the papers, respecting the *Gift-Hall Cheese Dairy*, that we have been induced to procure a true statement of the facts, which we have obtained from J. Wilson Patten, Esq., M.P., himself the owner. Gift-hall is a farm in Winmarleigh, North Lancashire, which the proprietor has in his own hand. Cheese-making is a prominent part of farming upon his estate in that district; the dairies of some of his tenants are celebrated, and obtain good prices, while others are sold at inferior rates. Mr. Patten, residing near the borders of Cheshire, and hearing of certain Cheshire farmers getting high prices for the London market, felt desirous to solve the problem, whether the quality of cheese depended on the *land* or on the *maker*, and if on the latter, whether as good cheese might not be made in Lancashire as Cheshire. He proceeded with the experiment in every way so as to give a fair and unbiassed result. He purchased fifty-three cows; and having to buy them off hand, of various breeds, they cannot be considered so select a stock as if he had been farming two or three years. Some calved in January, some in February, some in March, and others later. The first cheese was made on the 18th of April, and up to the 20th of October there were 320 cheeses made. These have not been weighed; but Mr. Patten has no doubt but they will fully average 50lb. each. There are some that weigh as much as 70lbs.; but when they are weighed we will give the exact weight. Of course, in estimating the weight of the whole dairy, we shall have the 'later makes' to add to them. At the estimate of 50 lbs. each, the quantity up to the above date will be 6 tons, 13 cwt., 1 quarter and 10lbs., calculating 120 lbs. to the cwt. No cream was taken off to make butter; but the 'whey butter' has all been kept, and of this there are either six or seven mugs, supposed to average about 60lb. each. We will hereafter give the exact weight of this, and the price it sells for. This celebrated dairy was sold this week to a respectable factor residing at Warrington, and who has a connexion with the London market, and the dairy is intended to be forwarded to London. The price is 63s., taking all together, including the spring cheese, which are never so good as the others, but not including the 'back ends,' which, of course, are also inferior and not ready. The celebrity of this dairy is owing entirely to the dairymaid, Mrs. Dutton, who formerly lived with Mr. Hixley, of Cheshire. Being always noted for making a choice dairy, Mr. Patten engaged her to come to Gift-hall, on purpose to conduct the experiment. The cheese-factor at Warrington had formerly bought Mr. Hixley's dairy when Mrs. Dutton made it, which probably led to the present purchase at Gift-hall. The above are the facts of the case; and we shall be glad to hear of the other farmers on Mr. Patten's estate, or in other parts of Lancashire, being able to equal this experiment. But to prevent disappointment, and to present the matter in a true light, we think a few words of explanation may be useful. And, first, there are certain dairies both in Cheshire and Lancashire that acquire a value by mere *fame*, whilst many others, equally good, cannot command near the same price. Second, the London market, for what is considered a first-rate article, requires a peculiar make, which is not easy to secure; but when a dairy happens to be exactly the thing,

unusually large prices are generally obtained. We do not think that the best Cheshire cheese are at all superior to the best Lancashire; but still fashion or fancy has given them superiority in the London market. And it is this fashion or fancy that has added so large an artificial value to double Gloucester and Stilton above their real merit. To show that it is not the mere fact of a dairy being of the *Cheshire* make that will command a large price, we may name, that while here and there a dairy in Cheshire was fetching as much as the Gift-hall dairy, and some considerably more, the general run of prices at the last Chester fair was from 42s. to 53s., and not a single dairy commanded the prices above named. It is proper that farmers should know that it is not by making *Cheshire* cheese merely that they will get higher prices, but by making that peculiar quality that suits the London market."

The following is a list of the *Horticultural and Poultry Shows* of which we are at present aware. We shall be obliged by any of our readers sending us additions to the list, and giving the address of the Secretaries.

HORTICULTURAL SHOWS.

BURY ST. EDMUNDS, Nov. 26 (Chrysanthemums). (Sec. G. P. Clay, Esq.)

CALEDONIAN (Inverleith Row), Edinburgh, Dec. 2.

LONDON FLORICULTURAL (Exeter Hall, Strand), Dec. 14.

SOUTH LONDON (ROYAL), Dec. 9+, 16.

POULTRY SHOWS.

BIRMINGHAM AND MIDLAND COUNTIES, 14th, 15th, 16th, and 17th December.

BRISTOL AGRICULTURAL, December 7th, 8th, and 9th. (Sec. James Marmont.)

CORNWALL (PENZANCE), January 10th, and 11th. (Secs. Rev. W. W. Wingfield, Gulval Vicarage, and E. H. Rodd, Esq.)

HONITON, January 12th. (Sec. H. K. Venn.)

WINCHESTER, December 1st. (Secs. G. W. Johnson and J. Colson.)

NURSERYMEN AND THEIR FRUITS.

AMONGST the many disappointments which flesh is heir to, few are more annoying than those connected with choice fruits. It is, indeed, exceedingly so for a person to find, after building expensive structures, or garden walls, and having his patience taxed by waiting some three or four years for produce, to find that his supposed Hambro's are Frontignans, or his desired Galande Peach is the Early Anne; yet these are things that happen every day somewhere, and the writer of this has undergone several severe disappointments of the kind in his time. Our nurserymen certainly are not the most negligent tradesmen of the day, by any means; but this grievance happens so frequently as to call on them for increased vigilance in the propagation of their fruits, and in the execution of their orders. Some years since we had determined to have a Galande Peach-tree in a favourite position: this was desirable, in order to furnish a link wanting in the chain of succession. One was obtained from a first-rate nurseryman, and in three years, on fruiting, behold it was a Royal George. Again, soon afterwards it became desirable to plant a very late peach, and a Late Admirable was chosen; and behold, on fruiting, we had another Royal George. Now, this was really infamous, and the annoyance was by no means lessened by a good ground for suspicion that the Royal George had been *knowingly* substituted.

It so happens that nurserymen have not at all times good trees of our more tender peaches; and the Royal

George, being a free grower, might, by a not over-particular foreman, be substituted. We do hope our esteemed friend, Mr. Appleby, will keep a watchful eye on such matters, and this we cannot doubt,—having been a gardener himself, he is keenly alive to the importance of accuracy in such things, and, by thus taking a stand from the first, will be in a position to render the gardening public a service.

Much is expected of all classes in these days, and the nurseryman must use whip and spur in order to keep up with the foremost rank. One of the chief features of our day is the division of labour in our various trades, and this practice has reached the nurseryman in common with the rest. Hence we have rose florists, fruit growers, cultivators of exotics for exhibition purposes, &c.; and we do apprehend that, as the tide flows, this division of labour is destined still farther to extend in the gardening world.

This is as it should be; for the business of a nurseryman was fast becoming of too multifarious a character to be well carried out by one firm in all its branches. We all know, by experience, that much less error takes place with such things as Roses by our rose-growers in these days than by the old mixed nursery system. We do not wish it to be inferred, however, that these rose-growers cannot supply a general order—by no means; but the fact is, they throw their chief strength into the roses, the rest being more of a subsidiary character.

The confusion in the nomenclature of our fruits, hitherto existing, has, indeed, been an enormous grievance, and seems to call either for fresh arrangements, or a far better administration of those existing. We are quite aware that what is called "the trade" is a very sensitive hydra-headed creature; and, doubtless, justly so; for, indeed, its well-being depends, in the main, on its integrity. And it is because we would fain increase even its high character, that we have the tenacity to charge it with the possibility of not being entirely immaculate. Moreover, we owe a duty to the public, whose precedency in this case is indisputable.

Under such circumstances, we rejoice to see a weekly report of that great emporium of fruits and vegetables, Covent Garden market, added to the pages of *THE COTTAGE GARDENER*, and to which the initial "H." is appended; and which letter seems to point to a first-rate pomologist, whose very style and fulness of information seems to betray him. These reports will be invaluable, but country folks would fain have the retail prices distinguished from the wholesale prices. This is, we are aware, a nice task to perform; but who shall say what is impossible in these days?

And here another word to our nurserymen, who certainly in their kind are nowhere excelled: no, not in any country. Since the million will have gardens, and possess the desire, without the practical knowledge, to avail themselves of superior fruits, some means should be placed within their reach of knowing at a glimpse what will suit their purpose. Catalogues they understand not; neither have they time or inclination to collect facts by a slow and tiresome detail, which would put them in a position with the really practical man in adapting kinds to their necessities, or as subordinate to their schemes. Here we must point to the importance of a growing art, the modelling fruits, as well as flowers, in wax. Why not have a cabinet of wax models of fruits as a very proper and necessary appendage to a nurseryman's counter, or shop-window? We are led to suggest this course in consequence of showing the very superior manner in which some of our rising artistes manage these things. Most of our readers have seen the Kew Garden's Museum, or if not this interesting cabinet of models of fruits, they have seen such things in the great metropolis. But we can assure them, that not in the metropolis alone are these matters well carried out, the

taste has fairly beset our provincials. At the last Liverpool exhibition, for instance, Miss Newton, the wax-flower lady, had a case which would not have disgraced the counter of the first seed-shops in Britain. This was mostly composed of pears and apples, and the merest novice would have traced the actual fruits by the lineaments therein portrayed. Incorrectness in colouring seems to be the only charge against these wax modellers; and, doubtless, it is a nice point to hit off the peculiarities of our fruits in this respect; but such difficulties will vanish before that extra perseverance engendered by the increasing demands.

Now, as it appears to us, there are at least two strong reasons why nurserymen might be expected to adopt such a plan: first, its utility to their customers; and secondly, for the information of their staff. As it is, but few of these persons can become familiar with the character of the majority of the fruits they sell; their young trees bear not whilst in their hands; in offering information, therefore, to ignorant purchasers, it is not expected, under such circumstances, to be very complete. But in these days we do hold it essential that every tradesman should be able correctly to describe the character of the wares he deals in. Advertisements are all very proper; catalogues very proper; but none of these will produce that impression on the mind of the anxious purchaser that well-executed wax models would do. For instance, we will here give an extract (descriptive) from the fruit catalogue of one of our most respectable nurserymen—

“GRAPES—*St. Peter's*; black; round; ripens late, &c.
PEARS—*Beurré Bose*; large; good; melting, &c.
APPLES—*Kerry Pippin*; small; first quality; table, &c.”

Now, these taken at random, may serve to illustrate the matter; and we may ask how any novice could form a just idea of the true form, general character, and peculiarly fine bloom of the *West's St. Peter's Grape* from so narrow a description? Then the *Beurré Bose*, which carries such an extraordinary impress on the table when in full size, so peculiar in character; the description would apply equally to a *Beurré Diel*. And to finish: the *Kerry Pippin* Apple; to say nothing of the very superior flavour and peculiarly high-colouring of the flesh, almost an orange colour, no one could picture to himself the handsome appearance on the table of a dish of high-coloured *Kerry's* in the middle of September. And now we will take it for granted that anything which will greatly serve and please customers it is the nurseryman's interest to carry out.

We remember, some years since, when the late Mr. Loudon—who was always aiming at progress—used all the influence his pen could command in trying to improve the character of our nurseryman's catalogues, which had previously been very dry affairs. This, although a somewhat up-hill work at first, at last progressed almost beyond his expectations; and now we have them in the plant way of as high a botanical character as could be desired; and, moreover, through a well-conceived grouping, most useful guides to the purchaser.

Such trays, or cabinets, then, we do urge would promote the culture of fruits, as well as a well-studied and correct nomenclature; and they would be a sort of guarantee that the tradesman was quite in earnest about his collection. They would also lead to increased inquiries on the part of the public; to an enlarged study of fruits, their characters, qualities, &c.; their origin; and, lastly, habits of growth. The last is an important matter, as on a knowledge of such facts must, in a degree, all successful culture be based. To this end we would beg to push the question a little farther, and to suggest that a leaf, a modelled blossom, and a twig of the kind in question, should accompany every

specimen. These, with a tabular card sheet, setting forth, in distinct columns, something like the following: *Uses; qualities; when in use and their keeping; bearing character; eligibilities as to site, &c.; peculiarities as to soil, or otherwise; and, indeed, any other information likely to be needed on the spot.* Now, this well carried out would, we feel assured, speedily raise the character of any fruit grown. The public would feel assured that the mere carrying out the idea would necessarily impose so much real attention to fruits on the part of the vendor, as would of itself lead to that fulness of information requisite to guide the public.

It remains, whilst on this subject, to offer another suggestion, for which we have not the assurance to claim novelty, but we possess a desire to see it made an indispensable qualification of one who aims at being a public purveyor in the matter of fruits. It is this: that every grower plant out a tree, under favourable circumstances, of every kind he receives into his catalogue, in order to let it attain maturity, and fruit if it will; its products tending, of course, to establish or destroy the identity of the wax model. This is surely a wholesome practice, both as to the salesman and his customers: in the former leading to careful selection and a facility of obtaining genuine grafts and buds—and in the latter, engendering that confidence which is the life and soul of all such transactions.

Had we a nursery we should cause these specimen-fruits to accompany all the principal lines or promenades, and every one should have a descriptive label, bearing reference to the model in the seed-shop; as also to the tabular account. R. ERRINGTON.

HARDY AND HALF-HARDY BULBS.

ON the first appearance of THE COTTAGE GARDENER, I promised the Editor, in my haste, that if I could not serve him in any other way, I could “do” the bulbs for him. Ever since, I have found that promises to Editors are like marriage vows—if you once break them, you will probably be out at elbows to the end of the chapter. As if to prove all this, I have now on the table seven folio pages full of the names of hardy and half-hardy bulbs, alphabetically arranged, with their natural orders indicated, all culled, industriously, from the pages of our useful COTTAGE GARDENERS' DICTIONARY by a correspondent (S. S. S.); and I am to give, from the epitome condensed by my friend, Mr. Fish, in the pages of the Dictionary aforesaid, an extended view of their propagation and cultivation, in conformity with my hasty promise.

If I were to do this in a consecutive order, from week to week, and from *Agapanthus* to *Zephyranthes*, I should be called to account; therefore I shall only give a chapter on them now and then, when nothing else is more pressing.

To save repetitions, I shall observe at once, that the different *soils for bulbs* ought to be well exposed for some time before using, so as that all vegetable remains in the compost may be quite decayed, and well incorporated with the mass by frequent turnings; that most bulbs are much improved by beds far deeper than many good gardeners are aware of; that planting with a dibber is injurious to many delicate bulbs, unless good clean sand is used at the same time, and if it is, planting with a dibber is the best practice. The reason of this is, that the sides of a hole made by a dibber will fall heavy on the bulb after the first frost or heavy rain, or, if they stand, will be apt to hold water too long, or make more of it pass down over the bulb than would do so if all the soil over the bulb were free and loose. By making a comparatively large hole for the size of the bulb with a sharp-pointed stick, or dibber,

and then putting in an inch or two inches of sand, then the bulb, after that by filling over the bulb, and all up the hole to the surface of the bed or border, with more sand, all the bad consequences of dibber-planting are got rid of, and a freer passage for the leaves through the column of sand is provided, and the sand, besides lying less heavily over the bulb, is not so apt to injure it as the soil is; besides, the wire-worms, and other grubs, which delight in the mischief they do to bulbs, do not like to work among sand. I suppose sharp silver or river sand tickles them too much to be pleasant. Add to this, that if the mark-stick or tally over the bulb is lost, you have only to scrape a little on the surface till you come to the top of the sand column, and then you are sure of the place.

Almost all greenhouse bulbs, particularly those of them which do not grow actively during our winter, may be grown in a border by the side of a wall, or other building, if they are planted six inches deep, and a slight protection is given from heavy rains and frost. A very small bulb will be able to push up its leaves six inches through a column of sand; and I have seen a *Crocus*, that was accidentally buried two feet deep in trenching a border, come up as vigorously in the leaf as if it were only four inches deep; and I have often seen the *Crocus* flower when the tube of the flower must have been a foot long, owing to the depth of the covering over the bulbs. On the whole, therefore, I shall lay it down as a rule, that all bulbs, whether hardy or otherwise, that grow to the size of an ordinary *Crocus*, may be planted six inches deep, if sand is placed all round them, and straight over them to the surface; and that four inches deep is the safest for such bulbs as do not grow to the size of a common *Crocus*; and that without sand, or very sandy soil, these depths are too much, although they may not show the bad effects for the first few years after planting.

I am rather ambitious that these papers on Bulbs should be as complete and useful as our present knowledge would warrant us to expect; therefore, if I omit anything, or say things that a reader does not comprehend—or if he knows, from *actual experience*, a better way than I shall point out—pray let him write directly, as soon as he reads each paper, and put what he means in as few words as possible.

AGAPANTHUS umbellatus, *albidus*, and *variegatus*, are three forms of the same beautiful plant—the blue African Lily. Some people believe that there are two more forms of it under cultivation, one much taller, and another considerably less than the common one. I cannot decide the point; but I believe the supposed difference arose from different modes of treatment—at least, I never saw any form of the blue one which could not be referred to the common sort. *Albidus* is not such a strong grower as *umbellatus*, and the flowers are of a bluish-white colour. It is a desirable variety, and so is the variegated one. There are no other bulbs that I am acquainted with, except some of the Asiatic great *Crinums*, which delight so much in our very strongest loams, fertilised by the richest manures, as the blue African Lily; and it will bloom and look green in a pot with soil that would stint an *Aloe*, *provided* abundance of water is given. I have known it to look well with the roots immersed in water for four months during the summer. It seeds freely with some gardeners, but is seldom increased that way, as it stoles, or makes side suckers so freely.

The most singular thing that I know of in the whole order of bulbs is, that this, a true evergreen, will flower yearly, for many years in succession, out in the open ground, after the leaves are destroyed every winter by frost: but of the fact itself, I am quite sure, I never knew a frost under 7° injure the leaves, while 10° or 12° of frost will kill them outright. It makes a bold,

fine-looking bed, and it is the most useful pot-plant we have to stand out in summer about the doors, or accompanying architectural works, or in terrace-gardens, as the leaves take no hurt with any wind, and the flower-stems are so stiff that a gale has no effect on them. It can be kept over the winter in pots, with less light and with harder treatment than any other bulb, and very little water will do for it from November to March. March or April is the best time to divide it for increase; but it may be divided any day from that time to October, if not all the year round. It is necessary to use a sharp spade for dividing it, for the roots are strong and much interlaced among each other. A small portion of roots will do with each division, and, in potting them, use strong, stiff loam and very rotten dung, leaving more room for watering than is usual with other plants, as it requires large supplies of water during the summer.

Agapanthus albiflorus is only a variety of the former, and of much less strength. It requires lighter soil, and more care in winter, but is not cultivated nearly so much as it deserves. There can be no question about getting new and useful varieties if the pollen of the blue one were applied to the flowers of this; but I never experimented on this family, and cannot say if this will ever seed.

Agapanthus variegatus also is scarce; but now that a taste for variegated plants is on the rise it will be more run after. Neither of the varieties make such free growth, or produce suckers like the old species; and both of them require lighter soil, and more careful treatment than the old species. I never heard if either could be trusted out-of-doors in winter; probably not. They belong to a section of the order Lilyworts, named after *Hemerocallis*, the day lily. The others best known of this section are the sweet tube rose, the beautiful *Blandfordias*, the splendid *Tritomas*, and the rigid New Zealand Flax *Phormium tenax*.

ALBUCA.—This is a genus of South African Lilyworts, belonging to the section of Squills (*Scillaceæ*), a section which abounds in beautiful bulbs, all of which cast their leaves when going to rest. The species of *Albuca* are numerous, and very ill defined; many of them come here with assortments of "Cape bulbs," but they are soon lost. The bulbs are generally small, light-coloured, and very tender-skinned; and the least mishap causes them to rot, as it does the *Lachenalias*, from the same country. Some of them are the very smallest bulbs at the Cape, and almost defy our attempts at growing them for any length of time; and others throw up stout flower-stalks, two or more feet high, with a crowd of little white flowers on the top. The most of them have white, or creamy-yellow flowers; but the whole family, like the *Alliums*, are more for botanic gardens than for general culture, and, what is singular, I believe they all dislike peat. Very sandy loam seems more favourable to them. I lost nine kinds of them in two years, by putting them in a peat bed, inside a cold frame. They came direct from the Cape in May, and that may have caused the failure, as all of them begin to grow late in the autumn.

We mentioned seventeen species of them in the Dictionary, but I much doubt if half that number could be bought in the trade. *Albuca major*, *fragrans*, *aurea*, and *viridiflora*, would give a good representation of the genus; but *fragrans* is very ticklish to keep. Pot-culture would suit them best; and the moment the leaves turn yellow, the bulbs should be turned out of the pots, and put on a shelf to dry in the sun for a few days, and then to be laid by in silver sand till the end of October. At potting-time, place sand round the bulbs, and do not water them till the leaves appear.

ALSTRÖMERIA, not *Alstromæria*, as some spell it.—As far as we know, all the species of this genus of fine plants have tuberous or fascicled roots. All of them in

our gardens live out the winter with little or no protection; or, if they are grown in pots, they require abundance of air, and large supplies of water while in a growing state. They delight in deep, rich, light soil, well drained, except *A. aurea*, which will do in stiff, damp clay, as well as in common, rich, kitchen-garden soil. The species are exceedingly difficult to distinguish from varieties, as much so as *Calceolarias*; and from one peculiarity common to them all, they are liable to cross each other in a state of nature: hence the great confusion in the names. This peculiarity is in the style, or female organ, which never ripens for the pollen till all the pollen is dead and gone in the same flower; but as the flowers do not all open at the same time, the stigma of the foremost flower gets fertilized by the pollen of the next that opens; meantime, it is as likely as not that strange pollen may find access when more than one kind grow together.

Another genus, called *Bomaria*, is often confounded with *Alströmeria*; but the distinction between them is evident, without any knowledge of botanical points. All the *Bomarias* twine like hops, but none of the *Alströmerias* do. Some of my friends assert that they crossed *Bomaria acutifolia* with a species of *Alströmeria*; but, I am so acquainted with the ways of both, that I would as soon believe in the union of the man-in-the-moon with Diana of the Ephesians. *Collania* and *Sphærine*, two genera of which we have no species in cultivation, intervene between *Alströmeria* and *Bomaria*; and, if any reliance can be placed on their characters, none of them would or could be crossed with either an *Alströmeria* or *Bomaria*. I am thus particular, because, sooner or later, both of them will be great favourites with the cross-breeder.

A. aurea, alias *Aurantiaca* (golden).—Native of the Island of Chiloe; flowers orange, streaked with red, on stalks three to four feet high; quite hardy in England; seeds freely, and increases by the roots as fast as Spear-grass. It ought to be as common as Poppies. I have had it four feet high in clay so stiff that it could not be dug without dipping the spade in water every other thrust; and I believe it would grow in a marsh, or at the edges of ponds or lakes. None of the family like dry chalky soil.

A. Cummingiana.—Named after Mr. Cumming, who first discovered it "on mountains near Valparaiso." It comes nearest to *Hookeriana*; flowers all the summer and down to November, in the open air, and is as hardy, apparently, as a Crocus, if planted six inches deep in rich loamy soil. The stalks are from ten to fifteen inches high, and the flowers of various colours—yellow, brown, and green, chiefly.

A. caryophyllæa (Clove-scented).—This is the proper name for the old *A. ligtu*, a stove plant, which requires light soil, and rest from October till March. It flowers soon after it begins to grow; and as soon as the stems cease growing the plants should be removed into a greenhouse for the rest of the season; without this change it seldom flowers at all, and now it is very scarce. The flowers, crimson and white, are very handsome.

A. hemantha (Blood-coloured).—Notwithstanding the name, the colour of the flowers is not much different from that of *aurea*; but in the meadows near Antuco, in South Chili, it sports naturally into white, vermillion, yellow, orange, and lemon colours. It is also the mother of thirty or forty varieties, called *Van Hout's Alströmerias*; and all of them rest three or four months, from July, and they ought to be taken up every second year, as they bury themselves deeper and deeper at every growth. A tulip bed, or one for hyacinths, made after the old florist school, suits them best, and they should be abundantly watered after they throw up for flower, and they grow slowly from November through the

winter, and, if they appear above ground early in the spring, they ought to have a slight protection.

A. Neillii.—Named after the late Dr. Neil, of Edinburgh, the best friend Scotch gardeners ever had. I am afraid this plant is lost; it was very difficult to manage. The flowers are of a very pink colour, with yellow blotches. I only saw one plant of this. It had all the appearance of being a genuine species, and wanted the twist in the leaf so common in the genus. Some of the species have been seen growing out of the clefts of the rocks, and this appears to me to be one of them.

D. BEATON.

(To be continued.)

AZALEA JAPONICA.—WREST PARK.

THE comparing of notes some time ago, if report spoke true, seemed to be much enjoyed by our readers. None require to be more reminded that there may be *unity* amid the greatest apparent *diversity*, than those who make gardening a pleasant recreation, or a professional pursuit. Often differences are more seeming than real; and the hair's-breadth of advantage that one system possesses over another, can only be demonstrated when, with all their details, they are brought closely in contact. Without this we are too apt, from our imitative faculties, to chime in practically with the dogma, that "what is best administered is best," while all the time there may be some little error in the very thing administered. A striking result so arrests the attention, that to equal the same, most people imagine that they must attend to every iota in a similar manner; while others, more experienced, and generally intelligent, can at once see, that in similar circumstances they can secure the same result with less trouble and expense. It would not be safe for the inexperienced to generalise, as their very ignorance might lead them to regard some apparently trifling matters as of no importance, though these, to the more conversant, would be regarded as the main cardinal points of the system. Hence, I find that the trifles of processes are the things about which young beginners chiefly concern themselves; by-and-by they will find that comparatively a few principles will sustain them, instead of a long calendar of routines. In the meantime, discrepancies in practice sadly puzzle them; they follow our advice this week, the opinion of another the week following, and the counsel of a third afterwards, and then how generally annoyed they are when result-time comes! Had they persisted in any one system all might have been satisfactory. They are told there are many ways to one end; and so there may be, and perhaps not one preferable to the others; but how or when is the end to be gained, when, instead of following out one way to its termination, you keep scrambling from one way across to another? I would meet every doubt if I knew them, and *could* solve them, and reconcile discrepancies if not beyond my ability. We are too constantly needing instruction to imagine we really know very much. Truth has been said to lie deep in a well; hence, few can see her, few find her, and many, with their cumbrous machinery, sink her deeper, and cover her out of sight. I believe she mirrors herself from the smooth surface of the unruffled pool at our feet, and when once we fairly get a glance of her, the only wonder is, not anything about the exceeding difficulty of finding her, but that we had been so blinded by pride and self-conceit as not to see her clearly before. We have all our pet systems, yet nothing would please us more than to be able to improve our favourite plans, or even put an extinguisher on them, and to adopt that which was decidedly superior. What better for this than the statement of difficulties and discrepancies, and the calm, friendly discussion of any differences. Thus,

though living comparatively in retirement, as many gardeners do, and perhaps not free from self-opinionatedness, the usual concomitant of such circumstances, we should, through the pages of our COTTAGE GARDENER, possess many of the advantages alike of the class-room and of congenial society, where thought is met by thought, opinion is tested by opinion, and mind is directly brought into contact with mind.

Azalea Japonica (see p. 82).—Our friend, Mr. Beaton, hoped I might fish out something about this interesting plant. I am at times half-inclined to envy him his present privileges, of being able to see everything that is wonderful, beautiful, and new. In the present case I am fairly upsides with him. I saw the plant before the branch was cut in the evening preparatory to its being taken to London the following morning. I can fully confirm the fact, that the huge panicle was only one of many; and so generally fine were they, that the selecting of the one to be sent was almost a matter of hap-hazard. Even Mr. Snow could not fix upon one that was markedly superior. The plant seemed about seven feet high, and the top nearly as much in diameter. Now for the *position*, as that is the most important matter as to the plant flourishing so well. Imagine you are standing on the east side of a high ornamental wall that runs from north to south. At the south end, a dwarf wall goes at right angles to the west, for the length of somewhere about twenty feet, and then it takes off, at right angles, to the south again for a good distance, constituting, in fact, the eastern boundary of the fruit and kitchen garden. In front of this wall there is a border for shrubs—the exact width of the short wall above referred to—so that the front of the border ranges in a line with the ornamental wall. At the extreme north end of this border, and hence on the south side of the short wall, protected, therefore, from the north and the west, rather freely exposed to the east, but a little shaded by higher things from the south, stands this beautiful plant. The border consists of deep sandy loam; but it is very likely that Mr. Snow gave his favourites a little assistance from leaf mould and peat when young. There are many fine specimens on this border besides, such as *Spiræa Lindleyana*, *Cupressus torulosa*, *C. thurifera*, &c. Whether the plant will thrive equally well in exposed situations, I am unable to say. It was the first time I had seen it in bloom; and I was rather surprised at the colour being whitish, as most descriptions had spoken of it being green. Even though it should be proved hardy enough for exposed places, yet the conservative wall (of which more anon) would be its proper position, as, unless it bloomed *earlier*, it would be apt to be destroyed by frost before the bloom expanded. No doubt we shall hear more about it.

I have mentioned all this the more, because, though *Wrest Park Gardens* lie rather low, they are protected in every direction. A description of the place would at once show this; but this would require considerable space, and I have not got one note on the subject. To give our friends such a slight idea as might incite them to a pilgrim's survey for themselves, I will present them with a few pencil-marks from memory—such as I frequently give, in lieu of a chart, by a few strokes of the pen, to strangers who are going farther, and who complain of a double difficulty: first, that when at a standstill they can find no one to exercise the inquisitive bump on; and, secondly, that when they do find a rustic, they have to stare at each other, like the respective parties in the last recorded miracle; and from the same cause, their respective *patois* being Greek to each other.

The nearest approach to *Wrest Park*, by rail, is *Hitchin*, on the Great Northern; and from thence it is distant somewhere about eight miles. From *Luton* it is

nine miles; and I forget how far from *Amptill* and *Bedford*. The road between these respective places passes the village of *Tilsoe*, where the main entrance is. Here, however, you enter,—I would advise you to go; and this shall be our first pencil *dot*. The gates are beautifully artistic; but what an avenue, or rather triple avenue within—formed of *Elms* and *Sweet Chesnuts*! The central, or carriage one is very unique. Had the Gothic style “loomed in the *future*,” the first architect of taste that had a glance at that avenue would have made it a matter of the *present*. The huge arms of the large trees, mostly naturally, but perhaps a little assisted, span and meet far above your heads, resembling a splendid Gothic cathedral. Ere long, as you go eastward, you soon descry the walls of the garden; Mr. Snow's house at the west corner of the north wall, house and wall being of an ornamental character; and the latter passing eastward until it joins the mansion and offices. The mansion offices, kitchen, fruit, and flower-gardens, are new: the park and main features of the pleasure-ground are I do not know or recollect how old, though constantly being improved. The mansion is in the *Louis Quatorze* style; and as everything connected with it was made from the designs of *Earl de Grey* himself, some conception may be formed of the chaste beauty everywhere apparent, and all impressed with one uniform character, within and without. The whole place may be said to be “self-contained,” that is, though it forms a fine feature in the landscape, when seen from high grounds, to the south-east, south, and south-west, you can, when there, see nothing beyond its boundaries. There is only one exception. Standing on or near the noble stone terrace, on the south side of the mansion, ornamented with statues and vases, you glance along a beautiful glade. First, there is a noble walk, thirty feet in width, proceeding right on, near to a large long parallelogram of water, where the walk parts right and left, and passes along both banks of the water, backed on either side with woods and pleasure-grounds. A pretty temple in the centre terminates the *home* view; but over its top you see bare and rugged and barren heights in the distance, which some might consider an agreeable relief, but which many more would feel to be a *Paul Pry* intrusion upon the soft, mellow beauty and rich luxuriance everywhere around. If such bare heights *could* be covered with wood, with a tower or cottage peeping through it, the effect would be harmonious and enchanting. In the woods and pleasure-grounds, on either side of the piece of water, are many walks, in which hours may be agreeably spent, more especially if accompanied by one versed in local traditionary, and legendary lore. Turning again your back upon the water, and approaching the mansion, you are struck now, if not before, with the vast extent of lawn. A considerable distance to the westward, you will notice a beautiful building, at one time used as a pavilion, or banquet hall. Anon, right and left, you stand opposite another avenue, terminated at either end by commemorative obelisks. Presently, another walk branches off right and left; that to the west leading you to the centre of a beautiful building, standing on the highest of a series of grass terraces. This building is filled with splendid orange trees, imported from the Continent last season, and now encased in *Beck's* beautiful slate tubs. As an architectural fabric, this house presents a fine effect; but as a habitation for plants, the back wall being opaque, the front is decidedly too massive and heavy. This is more apparent when, on entering, you perceive the roof is chiefly opaque, relieved only by upright square lanthorn-like boxes, glazed with glass all round, but from which the rays of light are too diffused before they reach the plants. The whole of the roof might easily, and more economically, have been of glass, without interfering in the least with the architectural effect. This is only one instance added

to the many, that the most accomplished architects are but indifferent gardeners. That such buildings would answer on the Continent, we believe; but have we the sky and the climate of France and Italy?

Retracing our steps, or taking a short cut across the lawn, we again get on the broad walk and approach the mansion. On the east side of the broad walk, and just below the terrace, is a scroll-like Italian garden, ornamented with marble figures, and having some beautiful young standards of Portugal laurels; but we must mount the terrace to see it well. The design seems somewhat intricate; but then every turn and bend are so graceful. Getting to the west end of the terrace, you see the mansion is there terminated by a conservatory. From this, as well as the rooms with which it communicates, a pretty vista is formed, through the opened doors in the divisions of the kitchen-garden. Between them and the conservatory is a wide grass drive, and a beautiful flower-garden, the beds having stone edgings, and the walks of gravel. The south wall, which bounds it to the north, is covered with interesting plants, such as the *Ceanothus azureus*, and the finer *Tea Roses*. The east wall already alluded to, in connection with the Azalea, along with other things, has one of the finest plants of the old *yellow Rose* in the country. I mentioned more than a twelvemonth ago, how fine the Geranium beds, &c., were in this garden.

Of the kitchen-garden I must not speak. I cannot think where I should begin and stop my pencil-marks. If not the best, it is one of the very best kitchen-gardens in England. Its extent is somewhere about five acres, and nicely divided by intersecting walls. The soil is for the most part artificial; Mr. Snow having received something like *carte blanche* to take soil wherever he could find it. The staple, therefore, varies according to the purpose wanted, but chiefly consists of a deep, rich, sandy loam, resting upon gravel. This, and being so fully protected, makes the garden a very early one. All sorts of fruits and vegetables thrive well. In the middle of one of the divisions is the chief range of houses: a plant-stove in the centre, with vineries and peach-house on the sides. In this stove, in addition to many good things, there is a fine collection of the Amaryllis group, most of them hybrids of Mr. Snow's raising. The Vines are very luxuriant. The Peaches have been seen at the Metropolitan exhibitions.

The division of the garden next Mr. Snow's dwelling is none the least interesting. In some particular borders near the house are beautiful old, but rare, herbaceous and bulbous plants. The centre part is chiefly occupied as the pit and frame ground, and here such crops as Sea-kale, Rhubarb, &c., are grown. On the south side, overshadowed by trees, is the fruit-room, a long building, perfectly dry, with double or hollow walls, double roof, means of giving air and letting off vapour at pleasure, a pattern that would please even our friend Mr. Errington, and the excellency of which has been proved in the fine fruit that Mr. Snow has shown for years at the early Metropolitan exhibitions. But in this division, besides some small Fig and Peach-houses, there is a range of small lean-to houses, near Mr. Snow's dwelling, on the east side of the west boundary wall. Here there is always something *nice* to be seen; and among other things, a fine collection of the *Gladioli* group; but what I mention them particularly for, is to remind amateurs that these are the houses I have some time ago chronicled for being heated so economically by small narrow flues underneath the paved floor.

I had no thought of making these dottings until I had finished the few words on the Azalea. If I had possessed notes, or told Mr. Snow of my intention, they might have been more interesting. But that may yet be mended. I forgot to say that the walks in the

kitchen-garden are mostly, and all will be, edged with slate; the gravel is firm and clean. One characteristic of the place is the *neatness ever apparent*, owing partly, no doubt, to the necessary supply of labour; but partly, also, to the innate sense of the neat and the beautiful, and a thorough enthusiasm for his profession, which must be accorded to the respected superintendent.

R. FISH.

JOTTINGS BY THE WAY.

(Concluded from page 106.)

NORTHAMPTON.—Close to the town there are two somewhat extensive nurseries, both well kept, and full of excellent stock, especially of hardy Coniferae, hardy ornamental shrubs and fruit-trees. The oldest one is now occupied by Messrs. Jeyes and Co. In front of one of the hothouses I observed a very fine *Juniperus excelsa*, fully fifteen feet high, and a very unique specimen. In the flower department, I saw several plants in bloom of a tall *Lobelia*, named *Queen Victoria*, one of the best of its tribe. The petals are so broad that they almost touch each other, and the colour a rich scarlet-crimson. I was so much pleased with it, that I purchased some for the purpose of hybridizing. It is a variety that every grower of such things should procure.

The owner of the other nursery is Mr. John Perkins. In it I observed a fine stock of trained Peaches, Nectarines, and other wall-fruit. In both nurseries there were some fine specimens of the best of the *Arbor vite*; the one commonly called the Siberian variety (*Thuja Siberica*). This is hardier than the Chinese (*Thuja orientalis*), and more compact than the American (*Thuja occidentalis*), forming beautiful pyramidal-shaped bushes of a bright green colour all the year. In that pleasing property it far surpasses any other species of *Thuja*.

Courteen Hall, the residence of Sir Charles Wake, Bart.; Mr Gardiner is the gardener at this place. It was the last I called at, and I saw several things that pleased me much. The place is about three miles from the Blisworth Station, on the Great Northern Railway, and is situated in a well-wooded park, very much secluded from the rest of the world. It may be characterised by the term "quiet," in the most exclusive sense. The flower-garden is rather extensive, and well attended to. I was much gratified with what was to me quite a novelty. The flower-beds were circularly disposed, and in the centre of each bed were several *standard* Scarlet Geraniums in full flower. Just at that season, the end of August, the standard Roses were out of flower, the summer-bloomers being past their season, and the autumnals or perpetuals had not come into bloom, but the standard Scarlet Geraniums were fine objects, and made a bright display of rich scarlet, causing no regret for the absence of Roses in bloom. Mr. Gardiner informed me that he first raises young plants, trains them up in pots, dressing off all the side-shoots till they attain the requisite height (four feet) before he allows them to make a head. He then plants them out in June, and they bloom till frost stops them. He then takes them up, pots them, and keeps them through the winter in some dry room till spring, then gently starts them into growth, and when the season returns replants them in the flower-garden. By this management they last several years. To prevent the winds from breaking off the side branches of the heads, he fixes a kind of ring or hoop to the stake that supports them, and fastens every shoot to this ring. I recommended the adoption of this method of growing Scarlet Geraniums, the effect is excellent.* Amongst

* The variety used for forming standards, is that known as *Mrs. Maylor*. What a fine one for that purpose Henderson's *Defiance* Scarlet Geranium would be!

the standard Geraniums I noticed a fine plant or two of *Cassia corymbosa* grown also as standards. This species is neither so well known, nor so much cultivated as an ornament to the flower-garden, as it deserves. Its bright green handsome foliage, and fine golden-coloured flowers, which are produced for a long season, render it very attractive. My able coadjutor, Mr. Beaton, recommends it, and from what I saw at Courteen Hall, I can confidently recommend it also, and in addition to its good properties as a low bedding-out plant, it forms a very ornamental standard, the colour of its flowers being very striking in contrast with the Scarlet Geraniums. Here, also, I noted some beds of the *Zelinda* Dahlia, not more than a foot high, and covered with its purple blossoms. Mr. Beaton would have been in raptures with them. Surely every cultivator of flowers in masses will try a bed or two of this showy, useful plant next year. Sir Joseph Paxton, amongst his 50,000 Scarlet Geraniums in the grounds of the Park at Sydenham, should have some thousands of this showy Dahlia, as an agreeable relief to the glowing colours of *Tom Thumb*, or his *master* either. No doubt he will, and thus bring this fine purple-bedder into public notice.

In the pleasure ground at Courteen Hall there are a few thriving Coniferæ, especially a fast-grown *Pinus insignis*, planted only in 1846, six years ago. It had attained, in that short time, the height of eighteen feet, with a stem as straight as an arrow, and regularly furnished with branches down to the ground. A more unique specimen of its kind does not exist in the kingdom.

This concludes my "Jottings by the Way." I trust, the few cultural hints, scattered, perhaps, too thinly, through them, will be found useful to many. I have yet in reserve a few notes on the *Bagshot Nurseries*, which I took on a recent visit to these celebrated stores of Coniferæ and American plants, on which I may scribble a paper by-and-by.

T. APPLEBY.

THE PETUNIA.

(Continued from page 127.)

Summer Treatment.—The season for this work commences in early spring. I shall suppose a plant to be in a 60-pot, and has passed through winter unscathed. It should be a low, bushy plant, well furnished with branches and healthy leaves. The soil, as directed in my last, should be duly prepared sometime previous, and a sufficient portion placed under cover to become partially dry. A good method to know when the soil or compost is in right condition, is to take up a handful, press it gently, and let it fall upon the bench; if it break into pieces it is fit for use, but if it clings together, it is a sign that it requires more time to dry. I do not approve of *quick drying*, by laying upon flues, for that method drives off the nutritious gases contained in the compost. Let it dry gradually, and, as it were, naturally, and then these gases are preserved. The soil being in suitable condition, let the plants be brought out of the greenhouse to the bench, and prepare the pots to receive them. If old and dirty, let them be clean-washed, and do not use them till they are perfectly dry; then drain them well in the usual way; place some rough siftings over the drainage and upon them place as much soil as will raise the ball of earth the plants are growing in to the level of the rim of the new pots; then turn the plants in succession out of the pots; remove carefully the drainage that may be attached to each ball without injuring the roots; place the plant in the fresh pot, and fill round the ball the new compost till the pot is full; then give a gentle stroke upon the

bench to settle the plants and new earth, and fill up the deficiency; the old ball should then be covered about half-an-inch, and a small space left below the level of the rim to contain water. Proceed thus till all the plants are finished, and then give a gentle watering, and the operation is complete. Return them to the greenhouse, and, if possible, place them close to the glass. As they grow, take care to stop each shoot, to cause more shoots to be produced, and thereby induce a bushy habit. The tops, if required, may be made use of as cuttings. In this stage the plants will require constant attention to keep them duly supplied with water, and plenty of air whenever the weather is mild; and this treatment suits most of the inhabitants of the greenhouse which is so far fortunate for the Petunia. About the middle of April, if all has gone on favourably, they will require a second shift into larger pots, into the same compost, using the same precautions as to drying the soil, draining the pots, and so forth. Most probably the green fly will now make its appearance, and must be instantly checked and destroyed by frequent fumigations of tobacco. It would be an advantage, when the weather becomes warmer, to place the plants in a cold frame or pit, upon a layer of coal ashes. There they will grow much stronger and more bushy than on the greenhouse stage or platform, and thus, as it were, lay in a stock of strength to produce a fine bloom. There is one disadvantage in placing these soft-leaved plants in such a situation, and that is, the mildew sometimes makes its appearance on the leaves. The best remedy I have found for this disease is a dusting of sulphur upon the leaves affected, and a large admission of fresh air on mild dry days. If a weak solution of liquid manure be given to all otherwise healthy plants, more vigour will be given to the system of each, and they will, with the addition of the sulphur, soon grow out of the disease. A third and last shift will be necessary in June; the plants should then be put into pots nine inches in diameter, and in these they are to flower. As soon as the usual inhabitants of the greenhouse are removed into their summer quarters, the Petunias will be in a fit state to take their place. Plenty of air must be given and the roof should be shaded with canvass bunting whenever the sun shines brightly. There, along with Fuchsias, and other summer-flowering plants, they will produce a splendid bloom of fine flowers for two or three months.

Winter Treatment.—As the Petunia is little more than an annual, old plants that have flowered freely through the summer will be so exhausted that it is hardly worth while to keep them through winter; but for scarce kinds or seedlings a winter treatment is requisite. Let such be cut down early in August, leaving all the young shoots that are near the soil; take them to the potting bench, turn them out of their blooming pots, reduce the ball pretty freely, so as to enable the operator to repot them into five-inch pots, give no water, and place them either in a close pit or in a shady part of the greenhouse, where no air can blow upon or over them. Shade closely for a week or two till fresh growth is induced, then inure them gradually; stop the top shoots, and give a small watering. Keep them through the winter as close to the glass as possible, and rather dry than otherwise through that trying dreary season. If these plants can be preserved, they will make fine, strong, early-blooming plants the season following.

T. APPLEBY.

(To be concluded in our next.)

EARLY SEA-KALE AND EARLY RHUBARB.

DIFFERING from almost every thing else, *Sea-kale* is in higher estimation when in a forced state than when

produced under natural conditions. This difference, no doubt, arises from the more complete exclusion of the light and air in the former than is often done in the latter case, as well as in the more timely service it renders at Christmas than it could in May. Leaving, however, a part to furnish fine strong heads in the natural way when spring sets in, let us see what can be done to have some at Christmas, or before, as well as the remainder of the winter and early spring months. Now, to accomplish this no time must be lost; in fact, when this paper reaches the mass of south country readers who have large quantities of this to supply, some progress in the way of hastening it will have been made. Leaving these parties to follow out the practice which their experience has taught them to be most successful, the less-experienced would do well to look over his beds, and after noting down their capabilities and general qualifications, he will see at once which is best to force on the ground it occupies, and which ought to be taken up and hurried into use in some other medium. If the instructions given last year have been carried out there will be a certain breadth of roots prepared expressly for the latter purpose, which ought to be carefully looked to now, as they present the readiest, quickest, and most economical mode of obtaining early Kale. Supposing, therefore, that a quantity of seed had been sown early in spring on some well-prepared piece of ground, had been afterwards thinned, ground-stirred, and every other attention paid to it calculated to encourage its growth, it will by this time have attained a root equal in size with that of most ordinary carrots, and, of course, have formed its buds (which are, in the first year, only one to a plant,) with a degree of strength and plumpness without which it is useless to think of a successful issue, or, rather, it is impossible to obtain fine, strong heads, except from plants which have accumulated a large amount of vital energy in their embryo buds. There may be cases in which the latter produces only a weak, sickly after-growth; and in all cases the forced is below the natural strength in that respect, and, in some instances, goes so far as to present us with a sickly, weak growth from a bud apparently set with considerable vigour; but this anomaly is easily accounted for; the sacrifice it has been called on to make is such as some plants would not live under—let alone flourish. The period of rest so necessary to all vegetation is denied this altogether; and an amount of stimulating heat applied to this with a view to forward its utility—nay, even to drive or hurry it on to the utmost of its speed; it is, therefore, no wonder that it sometimes becomes sickly, and not unfrequently refuses to grow altogether; it is, therefore, imperative on all those who wish to have this production as early as possible, and in good condition, to give it all the advantages that can tend to that result, and, of course, avoid all those evils having a contrary tendency.

Now it is well known that a considerable sacrifice has to be made in all produce hastened to a premature ripeness; and this sacrifice, like many others, differs in the degree of forcible means used; a short period of rest, followed by a gentle heat, gradually applied, is more likely to result in a successful issue, than an application of a moist heat applied to plants whose summer growth has hardly yet ripened. The weary traveller does not like to be roused again into action ere he has retired to rest at all; neither does vegetation, even of the most robust kind, of which Sea-kale is a very good example, as a less hardy plant would be killed outright with one-half of the ill-treatment this is often subjected to. Yet this one has its point of endurance, beyond which it is impossible to go without endangering its existence. Now these dangers are more numerous in the early part of the season than later on; the same amount of trial and hardship that would

produce excellent Kale in February, would either kill plants in December, or only produce a sickly growth at that untoward season. Yet Sea-kale is wanted at both these seasons. Greater care must, therefore, be exercised in the earlier crops, and the plants may be coaxed into producing fair, good, average-sized heads, when everything is supplied them necessary to their wants, and stimulation applied no further than is consistent with their well-doing. In this respect much judgment is required; the plant which, if left until March, could and would endure almost any amount of heat, languishes and dies now, when subjected to only moderate changes of temperature; it must, therefore, be reduced so low, as only to forward vegetation by those gradual means to which alone it is susceptible at this season. The best way to accomplish this, is to have the plants in a medium, over which a perfect command of heat may be attained. When forcing by fire-heat is going on in another department, there is often some odd corner contiguous to the fire-place where a deep box or two might be placed, to be filled with the roots of this plant, then to be afterwards covered with another box inverted over them, and some means taken to keep the atmosphere they are growing in as moist as possible.

A mushroom-house is also a very appropriate place for early Kale, where a shelf or bin may be filled with the roots, placed a few inches apart, and fine soil run in amongst them, with an inch or so of sand or coal-ashes at top. One or two waterings with tepid manure-water will be of service after they have started growth, or even before, if the plant be at all subjected to the drying effects of fire-heat; but either in this case or any other where the plants are so treated, a certain amount of moisture must surround the young shoots, or they will be tough, and not good. Now, if this be difficult to command at all times, it would be better to cover the plants slightly with a something to which moisture may be applied when necessary; moss or litter dipped in hot-water, to which a little salt has been added to kill all insects, will do very well; or it may be that a covering of coal-ashes may be applied, which may be put on so gradually as only to keep the shoots covered as they advance into growth; this, of course, will be best known by occasional examinations, and, with ordinary care, this way Sea-kale of good quality has been produced under circumstances of a very homely and makeshift kind, which every one is obliged to adopt in something or other. And if the amateur, whose means are only limited, be anxious to have Sea-kale at his Christmas dinner, he may certainly accomplish this yet by the means noted above, or he may even produce it by the ordinary method of covering it up on the ground where growing with gentle heating material, of which leaves are the best, and the result in the latter case will be equally good as the former, only not so quick; and when any other heating material than leaves is used, much uncertainty exists as to its overheating, and other contingencies which it is difficult to guard against. The only counter-benefits of the plan is, the little injury its roots derive, compared with those that are taken up and unavoidably mutilated; but the latter should be done as carefully as possible, in order to give the plant every encouragement compatible with the circumstances of its case. Plants, or, rather roots, carelessly taken up, half-broken and otherwise mutilated or deprived of one-half their supplying feeders to the crown of the plant, can hardly be expected to produce heads of any consequence. We, therefore, strongly urge on the amateur to take especial care of this; and in putting them into their forcing quarters not to crowd and injure them to an unreasonable extent, otherwise the produce cannot be expected to be satisfactory.

Although I have not mentioned *Rhubarb* in this article, yet it may be subjected to a similar mode of

treatment to that given for Sea-kale. A few old plants, taken up and planted out in some heated situation, will produce fine useful stalks some time before that growing in the open ground can be urged into action. The deep roots of this plant extending beyond the depth of the heat applied, render its progress more slow than Sea-kale; thus, in most cases, a few roots taken up in November, and put into some warm corner, will produce stalks long before that in open ground, although covered up. So that for all purposes, where an early supply is wanted, the quantity put in as above is attended with better results. It is almost needless to observe, that a well-prepared hot-bed, or one that can be heated by linings, &c., will answer the purpose for Sea-kale, Asparagus, and Rhubarb; but as frames may be all otherwise engaged, a less troublesome mode may serve the first and last of them. *Asparagus* must be accommodated with a frame and hot-bed, as it is important to allow it light prior to its being cut for use. But more of this anon.

J. ROBSON.

FLOWER-GARDEN PLANS. No. II.

THIS plan was only sent to us this week; but it is so appropriate for what a large class of our readers, in the vicinity of large towns, have been asking for, that I made choice of it in preference to another plan I had ready, but for a different class of subscribers.

I had a very sensible letter the other day from "Grumbler"—the last word in our language that I would use for a signature—in which he urged the great demand that is now made for such plans as are suitable for "block buildings," of which there are three hundred now in his own neighbourhood, not far from London, ready to be laid out. Block buildings, it may be necessary to tell our country cousins, are merely the ordinary villas, or suburban retreats; or, if you like it better, the "country houses" of nine-tenths of our great city chieftains, as they would say in the Highlands; every trade and calling having its own chief or chieftains, and among the rest of them our own correspondent, the "Grumbler." Why such villas, &c., are called "block

buildings," is best known to the speculative builder himself. He buys a field one hundred feet wide along a main road, and two hundred feet the other way; he runs a fence down the middle of it, and each division he calls a "block" of fifty feet. In the centre of each block, and twenty feet from the road, he builds a handsome villa, and sells the two to get some money to enable him to buy or lease a larger "field" next time.

Here, then, we have two chieftains and four gardens—two back and two front ones. The front garden is twenty feet one way, and fifty feet the contrary way. The back garden may be about one hundred feet; so that each block needs two plans; a plan for the front garden next the road, and another for the back, for flowers and vegetables, and "all manner of things." The all manner of things are already on the place, standing bolt upright and as green as leeks; the block builder took care of all that to make the best of his bargain; and here we are in a great bustle to put all things straight.

To make anything of a country life we must have flowers, and to show them off to the best advantage we must have "plans;" and while Mr. Robson is working in the back ground, preparing for getting vegetables "fresh and fresh like," here is our No. 2 plan for the front flower-garden, or for the front part of the back garden; and it is the very thing for such places.

Our worthy friend who kindly took the trouble, for the use of our new settlers, remarked, "notwithstanding its simplicity, I venture to send the inclosed plan, as I have a small flower-garden so laid out which looks exceedingly well. The beds are confined by box edgings, and being near the sea-side the walks are covered with shell-gravel." These are the "white shells" which Mr. Robson recommends for the surface-coat of his new walks (page 108), and capital things they are. They are as brittle as egg-shells, and crumble under the tread like "short cake" under the double teeth of a school-boy coming home from a country fair. The best use I ever saw made of these shells was one day last summer, on the spur of the moment. It was at one of the flower-shows at the Regent's Park. Her Majesty was expected, and the ground was soapy under the tents with so much rain, so, instead of laying crimson cloth all over the paths, as they usually do at the entrance when they expect the Queen, what did Mr. Marnock do but set a whole lot of able fellows with large bags of these shells, to strew them along the paths right round the tents, and they scattered them with their hands, just as Anster Bonn would deal out so much barley to a covey of the true Shanghai breed. In less than ten minutes the royal suite passed along, as dry and comfortable as any of you could wish. After seeing all this, and knowing my relish for comfortable walks, you will not be surprised to hear me chime in with Mr. Robson, "I would strongly advocate the use of shells to all who are within reach of them."

After plans for villa gardens, the next greatest demand has been for how to get the best contrivance for disposing of a collection of herbaceous plants, and how herbaceous plants might be made to do the work of bedding plants, for which sufficient accommodation could not be procured; and, last of all, the best shape for a flower-bed has been asked for. Now, it is certain that all these points depend entirely on taste; yea, what we call the *principle* of planting, whether it be flower-beds, cabbage-plots, plantations, or park scenery, is no *principle* at all, if we except the proper distances and soils for the different things we plant; all the rest is, as it ought to be, governed by taste. Therefore, how is it possible that one generation can lay down rules of taste for the next generation, or be itself governed by that of the past? It is just the same with individuals; and an individual who aspires to lead the public in any branches of taste, or branches governed by taste, ought to show no *particular* taste of his own, farther than that certain means are better for certain ends than others; anything beyond this narrows the channel through which taste flows, according to the influence of the leader. If THE COTTAGE GARDENER were to take up a certain notion, and say that such-and-such was the most tasteful way of arranging a garden, it has influence enough to do a vast extent of injury, by thus contracting the means of improvement. Let individual taste, therefore, have full play only in private, and it will soon improve on

itself. Let it send the results of its experiments, from time to time, to the full glare of light in these pages, and all will strive to follow, and some will endeavour to improve still further, and thus improvements *would* go on uninterruptedly, were it not for the misfortune that a book or an essay appears now and then, in which the author strongly advises the subject of his tale to be carried on according to some improvements which *he* has effected, or thought upon, to the exclusion of all others! Instead of being leaders, such authors ought to be pilloried, as a warning to the public against trusting to such dealers in universal medicines.

This is my second and last preface on the subject. I laid the substance of the two before the Editor, at first starting, in quite another form, but he would not hear of my plan. He told me, in effect, you must tell your tale yourself, in the best way you can, and that is all about it. Now, I hope I have done so sufficiently to be understood. In future, I shall be like Bailie Nicol Jarvie, in Rob Roy—"A Bailie," "a magistrate," and "a free-born citizen," sitting, not in judgment on the different styles of tastes in laying out flower-gardens, but to give a fair hearing and a suitable introduction to all styles and plans that are sent to me; so that we may all learn and improve as we go on.

The plan before us is very accommodating; it may stand either in the front of a villa, next the road, or nearest the country. The front-door, or the centre of the house, may be opposite 1-1, or opposite 2-2; or it may be a distinct feature in a part away from the house. 1-1 and 2-2 would be one of the best arrangements for "herbaceous plants," and the middle figures for gay bedders. Or if the house stood behind 1, the opposite 1 might be of Dahlias, or with Dahlias and a row of the best Hollyhocks behind them. The same with the 2. 2. No one can go up straight to the middle of this garden; and this is always a wise arrangement, particularly in plans of limited extent. Again, 1-1 and 2-2 might be made the "Rosary," surrounding the flower-garden, with rose-arches thrown over the four corners; and if so, pillar-roses, or high standards, ought to run along the centres of each long bed. Those who object to tall standards, and I am one of them, would have pillar-roses about seven feet high, or height of the rose-arches, and festoons from pillar to pillar, and joining the arches. For any of these suggestions, the long beds would need to be at least six feet wide, and eight feet would be better, particularly for the roses, as we must suppose a good pillar-rose to be at least two feet through at the bottom, and the festoons will need as much room as the bottom of the pillars, to allow them to swing about with the wind. Then with an eight-foot bed we have only room for three rows of dwarf-roses on each side of these beds, and hardly that. Once more, if these long beds were only three or four feet wide, and raised six inches above the general level, filled as Mr. Appleby says for florists' flowers; the best late Tulips would do in the one farthest from the house; the best *Early Tulips*, being dwarfier and earlier, next the house; and the side ones with Hyacinths, bordered with Turban or some common Ranunculus. In the summer, all the long beds, being planted with Roses, might be edged with the white *Campanula pumila* at six inches from the sides, or the white *C. carpatica* at nine inches. The plants standing nearly close to each other in the row. Last of all, the two No. 1 beds might be planted with Mayles's *Variiegated Geranium*, and *Beauty supreme* Verbena, plant for plant; or the one next the house this way, and the opposite a shot-silk bed, with *Verbena venosa*, and the old *variegated Scarlet Geranium*. For the middle beds 3-3 ought to have plants a little taller than 4-4 and 5-5, and the dwarfest plants to occupy the four centre beds. If the front door, or the drawing-room window stood opposite 2, then 4 and 5 ought to be of one colour, and if a different plant is used for each, their heights and way of growth ought to be as much alike as possible. The same colours should be repeated in the opposite 4 and 5; the plants either straight across or corner-wise—that is, the plant in 4 to be repeated in the 5 at the opposite corner, or just across in the other 4. On the other hand, if the door or window is opposite 1, then 4-4 should be of the same height and colour, and 5-5 may be of quite a different colour, and the plants a little higher than in 4-4, as they are farther from the eye. For the same reason, the colour in 5-5 should be brighter, or more telling. If 1 is

of the variegated *Geranium* and Pink *Verbena*, we have a strong pink on a white ground; and no blue, lilac, purple, or white should stand in 3 in front of it. I would put the *Kentish Hero* *Calceolaria* in this 3, and a bright-yellow *Calceolaria* in the opposite 3. I would plant 5-5 with two good purples, or light rose-coloured Verbenas or Petunias, and 4-4 with pink or dark-bluish flowers; or, say the right-hand 5 was full of *Shrubland-rose* Petunias, and the left-hand 4 with *Saponaria calabrica*, then the right-hand 4 with pink Ivy-leaved *Geranium*, and the left hand 5 with *Petunia Devoniensis*. But any other plants coming near to these sizes and colours would do just as well. It is the firm opinion of the best planters, however, that matching the height of plants is as essential as the disposition of the colours, if not more so. Also, to suit the height to the size of a bed is of first importance: thus, a circle ten feet in diameter, quite flat, and planted with *Tom-Thumb* *Geraniums*, all of one size and age, though brilliant in the extreme, would still be "bald, like a cat's face," in the eyes of an artist, as I once heard Sir Charles Barry remarking to another great artist, speaking of a great building. The same *Tom-Thumbs*, planted in a circle not more than four or five feet through, would make a gem, and a person who did not know on what part of the body gems are worn, would be just as likely to wear one across the bridge of the nose as anywhere else; and it is as essential in placing heights and colours in flower-gardens.

We have still four beds in the centre of our plan, and if you keep in mind what is said of fitting the height of a plant to the size of the bed, if you never planted a bed before, you can plant these four just as well as any of us. We have got the plants and colours so disposed of in the rest of the plan that you cannot possibly mar the effect or add much to it. I would plant the four beds with scarlet and white—either Verbenas or *Geraniums*—or with four shades, as *Lady Mary Fox*, *Diadematum rubescens*, *Quercifolium coccinea*, and old *Diadematum*. Or, I would keep them for any of whatever were my pet plants, as no colour will much affect that part of the garden. The little blue *Lobelia* and yellow *Oenothera prostrata* would do there. All the beds might be large enough to allow these centre ones, in proportion, to be three feet on the sides; in that case, two of them with *Saponaria calabrica*, the other two of *Sanvitalia procumbens*, would look very well indeed; but then there should be none of the *Saponaria* in the plan. After all this, there are ten other different ways to manage this plan equally well.

D. BEATON.

ALLOTMENT FARMING.—DECEMBER.

Frosty, dark December! the very sound of this month is but too apt to engender in the sons of the soil apathetic feelings. The iron rule of the Ice king, the investment of the earth's surface with a mantle of snow, or, what is generally the alternative, sleety, drizzling rains, turning midday into a kind of twilight, appear to furnish a solid excuse for a total neglect of the soil. And, indeed, either of these conditions, whilst it lasts, is a serious impediment to garden operations. Still, let not any man fancy that the smell, by anticipation, of the Christmas pudding, can alone furnish a thorough excuse for hanging up the spade and mattock to rest for a month or two. Of course, the ordinary labourer has no overplus time to spare from his regular employ, which, after all, is the main thing, and to which all other things must give place. He may be, which we hope he is, in full employ, his services regularly required by his master. But most employers will grant a day by chance for a special matter, the thing properly explained. If we were to seek for a fault in the allotment system, as connected with our agrarian population, it would be where too much temptation exists to absent themselves from their regular employ; in consequence of which a host of ill-feelings sometimes arise. The winter has been, perhaps, an unusually protracted one, or the early spring months excessively wet; at last a favourable period arrives for working the soil; the employer is all on tip-toe, of course, for he has a rent to pay, and a living to make. Well, the very approach of fine weather and long days is the signal for the labourer to begin a spring career on his plot, and if

that plot is nearly a statute acre—as is frequently the case in some districts—there is too often an end of all comfort between the employer and employed. We do not say that such cases are the rule; the exception they are and need be; but when they do occur they are not a whit less a grievance. The only cure for all this is with those who grant allotment plots, to take care that they are not sufficiently large to draw the holder away from his ordinary duties. By experience, we are assured that half-an-acre is too much, and we should suggest a quarter, as well meeting the average of cases. But, perhaps, these remarks apply more to the holders of cottages, to which land has long been attached; with these we have had *much to do* during the last twenty years as labourers under our superintendence, and can bear ample testimony to the asperity of feelings induced by having labourers who would be ever at their post in the short or bad days, and off without notice on the first fine day, when real business might be advantageously carried out. But now for the business of the allotment or cottage gardener, for our duties lie with both.

First of all, we will ask, Is the land *ridged* from which crops have been totally removed, and which is liable to be soured by rain or snow? That is to say, is it piled up to mellow by the winter's frosts, and to drain from the winter's snow? If not, you have omitted a most necessary proceeding, which we assuredly have not omitted to advise in former papers.

In order to save repetition, we beg to refer the attentive reader to page 65, on the improvement of the staple, and pass on to think about rotations for the ensuing year; for we will try and persuade every one of our allotment friends, yea, and cottage gardeners too, to spend the dull evenings, which are not only approaching, but at our threshold, in conning over the various modes or schemes of cropping, by which a *profit* may be realised, and the domestic comforts of the family increased. Those who may feel thus inclined, may refer to many back allotment papers for suggestions, and we will here again offer the results of many considerations of this question, carried on for some years, in which, according to one of our fine writers, we have endeavoured to "make each day a critic on the last."

We do take it for granted that the production of *keeping roots* is the chief basis on which allotment cropping ought to rest, and that all mixed cropping ought to be held subordinate to this principle. Of course, if no pig is kept, it materially alters the question; and if *both* cow and pigs, more so still. The latter being quite the exception, we have, in general, paid less attention to it; but as to a pig alone, that constitutes, doubtless, the majority of cases.

In connection with this view of the case, we hold another maxim—viz., that deep digging or trenching ought to be had recourse to every third year. Such being admitted, it becomes a consideration what class of crops to trench for. As to the benefits derivable from trenching, it is to be hoped that to the minds of many of our readers they are quite familiar; to others we say, that all crops with which we are acquainted, unless of a very stubborn character, enjoy a taste of the subsoil, which appears to contain certain inorganic matters of importance to most crops. This, however, is not all—depth of root to crops that have to undergo culture a whole summer and autumn is of immense importance. Two plots of the *Swede Turnip* shall stand side by side, the soil equal in quality, and in the same condition as to previous cropping. No. 1 shall be trenched two feet deep, using the manure between the spits; No. 2 shall be dug the depth of a half-worn spade, which we will call seven inches, and the same amount of manure dug in. And now we will suppose a hot and dry time in August. The almost certain result would be, that No. 2 will grow with more rapidity, if showery weather, for the first month; but as soon as overtaken by drought it will become stationary, and not only that, but mildewed. The greater expanse of foliage will only subject them to a higher amount of elaboration when the drought comes, and if they cannot extend their fibres in a degree commensurate with the drought in their foliage, they begin to flag, and this flagging indicates the condition of sap requisite to encourage the mildew. By this time, No. 1 shall be striking downwards, and shall have fibres more than a foot in depth, where there is a permanency of moisture, whilst No. 2 has four-fifths of its

fibres in mere dust. Thus stands the case with most crops that we have experimented on; and we boldly affirm that the case is in no way overcharged. The destruction of weeds, insects, &c., although we hold it to be a subordinate consideration, is by no means unimportant; and thus, altogether, surely a case is made out for a periodical trenching.

For general purposes, we do think that the crops for an allotment may be placed in three equal divisions, under the heads—Roots, Miscellaneous Crops, Potatoes. Now, although it is not intended *rigidly* to enforce so *very distinct* a separation of objects, yet, on the whole, we would adhere to it as a maxim, and, above all, take it as a guiding principle annually, as the allotment planning came round. This will keep the cultivator from confusion, and by it, if tolerably well adhered to, he will always be in a position to know the past history of his plots and prospective hopes. These things being settled, mixed or "stolen crops" may be so woven in with the system, as not to derange the main plan; and this must be from a full consideration of the habits and periods of the principal crops.

Although *Potatoes* may be fairly classed among the root-crops, yet in this we would keep them separate; they require separate culture in these days, and, moreover, by separating them the chief of the remaining root-crops will be the deep-rooted or fusiform class, for which depth is particularly essential. This brings us to our point: the ground in three divisions, one division trenched annually, and that for the root-crops.

Now these root-crops, under such circumstances, we would term renewal-crops, or renovators—not that they detract less from the soil than others, but that extra depth and extra culture leaves the land in first-rate order for other successions. They will prove excellent preparers for either Potatoes or the Miscellaneous section; but where many of the Cabbageworts are grown, we should prefer following them with Potatoes, without a particle of manure, presuming the ground to have been liberally treated for the Cabbageworts. We have no more space for rotation affairs, and now beg of our little gardeners to study this matter during these long evenings, and to lay on the fire an extra log, for the wind begins to whistle through every cranny. When they have once decided, let them get a stick or two, shave one end flat for writing on, get a little thick white paint, which rub thinly on the writing part, and *immediately* write the name of the crop; if succeeded by anything, or to receive a "stolen crop," with the circumstances of manuring, digging, &c.

Thus—"Broad Beans sown early in February, rows three feet; Kale planted between, sown March. Beans succeeded by Cabbageworts, or Coleworts, sown middle of June; lightly manured, and dug in end of November into ridges; ridges levelled down in beginning of February." We have written in full, but an ingenious mind will soon make short work of this by a system of abbreviations, or substituting signs or marks for words. Thus, sown may be represented thus, . . . ; planting thus, T representing a dibble, commonly called a "dibber;" the months by first and last letter—thus, My, May, Jy, July, and so on. Even the digging and trenching may stand thus, 1, 2, the one single, the other double digging; and the period of the month by b, m, e., signifying beginning, middle, and end. We now take leave of this portion, having "broken the ice" fairly.

Priming for Spring Crops.—Let not our friends despise the soot of their chimneys, but hoard it up for mixtures to drill with; this we call priming. Such, mixed in spring with burnt or charred rubbish, and the residue of old manure heaps, old leaf or vegetable soil, and a little of Messrs. Gibbs' Peruvian Guano, all well blended, will soon set your young plants on their legs.

Ditches and Fences.—If your allotment or garden has anything of this kind, pray do not delay till the spring, if you can possibly carry anything out. Experience tells us, that spring, if fairly personified by the painter, might come in the shape of a young, strong, and raw, broad-shouldered fellow; but of what use is it having broad shoulders, if they are compelled to do double duty. If his sage old parent, winter, has been a far-seeing old gentleman, and has cunningly had a portion of the burdens destined for the young squires shouldering got rid of before-hand, why all we can say is—a wise sire, and a lucky youth. But joking will not

do; and we say, at least clear out water courses, mouths of drains, or anything else that tells of a stagnation; in fact, any boundary matter also; and if scourings, dubbings, ditchings, or any bulky vegetable matter comes to hand, pray secure it; try to mellow, and to decompose it.

In conclusion, we advise, make up your *rotations* betimes; proceed with not only improvements where possible, but necessary business, ridging and digging, if feasible, for early spring cropping. And, above all, look to your manure-heaps; if not yet wanted, throw them up into steep conical heaps, in order to keep the rain out. If any one doubts the effects of much rain on a heap of muck, let him look at the colour of the water in the nearest ditch below the muck heap, or watch his wife's teapot.

R. ERRINGTON.

THE APIARIAN'S CALENDAR.—DECEMBER.

By J. H. Payne, Esq., Author of "The Bee-Keeper's Guide," &c.

ANSWERS TO MANY QUESTIONS.—Numerous have been the questions to me of late: "What am I to do with my weak stocks; how can I keep them through the winter?" To all I would say, as I have already repeatedly done, *feed them well*, in the manner already directed in the pages of THE COTTAGE GARDENER, and you may keep them through the winter.

ENEMIES.—Guard well against birds and mice; except a vigilant eye is kept upon these, sad inroads may be made amongst your stocks, especially in exposed situations, and at this season they are most to be feared.

VENTILATION.—Look well to this matter for the next two months, where the bees are in boxes or straw hives with wood tops; hives entirely of straw will not require it. A small opening at the top of each box, with an inverted tumbler placed over it, will be sufficient.

FLOOR-BOARDS.—Give the floor-boards a cleaning, and, at the same time, see that the hives have not suffered from the late unusually heavy rains. Freeness from damp is essential to their prosperity, for with it the richest stocks are sometimes destroyed.

SNOW.—Be particularly careful to shut up during the time that snow lies upon the ground, for when the sun shines upon the hives at that time the bees are induced to come out, when numbers perish, by which the hives are much depopulated.

DRIVING BEES.—Thanks are due to "Investigator" for his paper in THE COTTAGE GARDENER of the 11th instant. I willingly tender him mine; many practical hints may be gathered from it, even by those who are far away from the "Moors."

ERRATUM.—In my last Calendar, in Mr. Taylor's letter, for *working* read *making*.

COST OF KEEPING SHANGHAE FOWLS.

ALTHOUGH, Sir, I am, with yourself, very willing to credit the accuracy of "Gallus's" report of his experiments on feeding, and feel, as must all interested in the subject, much indebted to him for the trouble he has taken in the matter, I must, for one, confess that I am very far from thinking those experiments conclusive on the points attempted to be definitively settled by them—namely, as either showing that the Cochinchina breed are larger consumers of food than either the Spanish or the Dorking; or, supposing this to be so, as proving that, therefore, the former is a less profitable breed for the cottager than either of the latter. I think, indeed, that very few of your unprejudiced or disinterested readers will be inclined to admit that those trials, opposed as they are in their results to the experience of so many equally reliable authorities, are of so satisfactory a nature as to justify "Gallus's" opinion of them—that they will of themselves suffice to plead the cause he has undertaken; and, with your permission, I will endeavour to point out in what particulars they appear to me wholly unsatisfactory. First, then, and in addition to the exceptions taken by you, I altogether object to *chickens*, or any but full-grown birds, forming part of experiments made to ascertain the points in question. It will hardly be maintained by Anster Bonn,

or any other champion of the large breed, that birds which, when full-grown, weigh as much as twelve pounds, will require no more food to bring them to maturity than others which, when full-grown, only attain half that weight, which is not far from the relative difference in the weights of Cochins, on the one hand, and Spanish and Dorkings on the other; consequently, if the rapidity of growth is in all proportionate rates in the large and smaller breeds, it cannot but follow that chickens of the larger breed will consume most food. But it does not necessarily follow, as I will presently attempt to show, that the largest consumers of food, when chickens, are therefore the least remunerative breed to keep.

A less obvious, but not on that account a less valid objection to admitting any but full-grown birds into these experiments, is the fact, sufficiently notorious to observant amateurs, that at different and uncertain periods of their growth, chickens, particularly of the Shanghae breeds, increase in weight very much faster than at others (this is partly seen by a comparison of the weights in tables 3 of "Gallus's" experiments); and not unfrequently, after continuing for a time in a slowly-growing state, they will, with a sudden impetus as it were, "go ahead," and develop so rapidly in shape and size as in a few days almost to outgrow the recollection of the feeder. At such times their appetites are most voracious, and the amount of food consumed is in no proportion to what might have been a fair estimate of it before this impetus in growth set in. Hence, results derived from experiments with birds subject to such adventitious influences must be of questionable authority. These objections are, I think, insuperable to the conclusiveness of "Gallus's" experiments; but there are others which, though they may appear to some captious and trivial, to those who are aware of the difficulty of obtaining reliable results in all experiments on the feeding of animals, will of themselves be thought sufficient to preclude safe deductions being drawn from a consideration of the abstract results of these trials. Such are—the want of sameness in the condition of the old birds, some being in moult, some laying, and others not; the unequal advantages to which the different lots were subjected—one lot having the run of a large plantation and stubble field, and another access to a large grass field and plantation, while two more lots were confined to a wire cage, and occasionally fed with bread by children; apparently, too, some little difference in the description of food given to one or two lots, and a few days variation in the date of commencing the trial in lots 4,—none of them, perhaps, very important circumstances individually, but in the aggregate, and whether regarded as in favour or against any particular view of the subject, must, from the want of uniformity and precision in the details, militate against the accuracy of the results.

I suspect that the objectors to the Shanghae and Cochinchina breeds, on the score of their being such large consumers of food, have come to this conclusion from their experience of what the *young* birds of these breeds are capable of in this way, when contrasted with those of the smaller breeds; but surely this is an unfair comparison, unless the much greater weight of animal food obtained as an equivalent, and the rapidity with which that food is produced in the one case over the other, is also taken into account and compared. It is a well-known law in the economy of healthy-growing animals, that the great bulk of the nutriment of the food consumed, or all but a minute portion of it, is applied to build up the various textures of which the body is composed; and as in edible vegetables, so in the case of animals used as food—the more rapid the growth and formation of these textures the better will be the quality, the more delicate the consistence and flavour of the food so produced. Looking, therefore, at the "chicken" merely as a machine for the conversion of cheap materials into a costly article of animal food, the point to be considered by those who have this object in view, and would be guided by motives of economy in their selection is, not which machine will consume *least* of the raw material (for, in any case, the equivalent in the manufactured article will be in a fixed proportion to the amount of materials employed), but which will manufacture the article most expeditiously, and give the quickest return of serviceable food. Here, I think, it will not be questioned,

that the Cochin-China breed possesses this property in a pre-eminent degree—seeing that their chickens at four months old will outweigh those of Spanish or Dorking at six. And with regard to the quality of their flesh, the general opinion expressed by your correspondents is, I think, decisive that, although there exists as yet some little prejudice against the long legs and colour of the skin, they come behind no breed in the essentials which render this description of food so valuable an adjunct to the table. And, certainly, my own opinion, founded on pretty extensive trials in this agreeable particular, is not opposed to that conclusion.

Take, now, the other commodity, to the remunerative production of which the attention of the cottager would be more especially directed in forming his estimate of the most suitable breed, namely, "Eggs." In the full-grown laying hen, as in the growing chicken, only a very inconsiderable part of the nutriment, as compared with the whole extracted from the food eaten, is required to replace the loss occasioned by the waste which, to a certain extent, is continually going on in the bodies of all animals. By far the larger portion of it is diverted to supply the specific *drain* which is necessary to, and results in, the formation of the egg; and it will be found, with here and there perhaps an exception, that in proportion to the food consumed will be the fertility of the hen in her yield of eggs. So that here, again, if we regard the hen as an "egg-producing machine," the question of preference with the cottager ought to be—not which breed of hens are the smallest eaters (for the number of eggs laid being in the ratio of the food consumed, he will assuredly with small eaters also have but indifferent layers)—but, which breed will manufacture their food most expeditiously; which, in short, possesses the greatest egg-producing power, irrespective of the food consumed, which, however, will be a true reflex of that power. Now, my own opinion is, that nothing *can* excel the Cochin-China breeds in the number of eggs they produce. Spanish, I believe, may equal them in this respect, and even surpass them in weight of eggs, and though, the quality of the eggs being the same, I should esteem this an important point, it would be of little benefit to the cottager so long as eggs are sold by number and not weight. But the superior richness and flavour of the smaller egg will, I think, in the long run, prove more than a set-off against any deficiency in its size, for I am quite of opinion that when the breed becomes more general, this superiority will be so notorious as to enable them to command a better price than the eggs of any other breed, particularly in our large towns, where quality, in all that conduces to the gratification of the palate at least, is so well appreciated. Allowing, however, the merits of the two breeds *as layers* to be equal (I do not here include Dorkings, as from my experience of them they do not, as layers, merit a comparison, and this defect will, I think, partly account for their being, which they indisputably are, so excellent a fowl for the table), there remains one point, and to my thinking *only* one, on the question of the alleged greater cost of keeping Cochins over Spanish, and that is in the supposed case of a cottager who may have no market for his chickens, and whose sole object, therefore, in rearing poultry, would be for the profit of their eggs. Being told that both breeds are equally prolific layers, but that Cochins, from their quicker growth and greater size, were the most expensive to keep *as chickens*, unless he could dispose of them as such, he might not unreasonably ask whether there were any advantages in the large breed, over the small, which would compensate for this difference in the cost of keeping, prior to the period of laying. On this point your readers have had such ample means of forming an opinion, both from the excellent articles of Anster Bonn, and the interesting communications of so many able correspondents, that I am unwilling to say anything on the subject, further than that in my own opinion, *more* than an equivalent, for this small additional cost, will be found in the fact of the Cochins excelling, not only Spanish, but all other fowls, as far as I am conversant with them, as *winter layers*. A consideration of all others perhaps the most important to the cottager.—SHANGHAI MANDARIN.

HARDY HERBACEOUS LOBELIAS.

LOBELIA SYPHILITICA.—How rarely is this beautiful plant to be seen, in either a choice selection, or even in botanical collections, where anything and everything should be kept for the lovers of plants. Notwithstanding the fine high colours of the *Lobelia splendens* and *fulgens*, and their varieties, we think this much prettier, and very desirable to mix with them in a bed or border. Indeed, we think this the hardiest and handsomest of all of the upright-growing "Cardinal flowers." It rises from two to three feet high; the whole plant is of a pale green colour, and leafy from the root to the very tip of its flower-stems, and a profuse bloomer; its flowers are of a light-blue colour; indeed, the whole plant makes a very striking appearance in the flower-border at all seasons, for even its leafy crowns are always visible, forming evergreen bunches in the borders during winter. It is a native of Virginia, and was introduced to this country in 1665.

In order to keep it growing to perfection it should be taken up, divided, and replanted every year in the spring months. The soil cannot be too rich for it, and it should be planted in rather a cool situation. We always choose new spots for these plants every year in our borders, and take care to keep a number of plants, in particular of any choice kinds, well working up the natural soil, and adding to it a spade or two of turfy-loam and leaf mould in equal parts; then planting a compact bunch of the plant, and with the hand pressing the soil about it snug and firm. Its time of flowering is from August to October. Being anxious to have enough of it, we have often put a bit of it in the kitchen-garden, at the foot of some of the vegetable quarters, where rich enough is the soil, and which is a new place too to the plant. These make fine specimens to lift into pots, in September, to take to a Horticultural Exhibition. Sometimes we have turned this plant out again to take its course like others in the borders until spring; and at other times we have indulged it with a place in the cold-frame, with others, for winter protection: and certainly this is a safe method to deal with it in localities where there is any fear about losing it; but with us, self-sown plants come up annually, somewhere or other about the borders, without any care. Two-years-old plants, however, we have always found to tire of their places, and to dwindle or die off. There is a white variety of this plant which I have never seen: probably it is not so hardy as the above and rarer.

LOBELIA CARDINALIS.—This is a native of Virginia too, and perhaps a rarer plant than the preceding. I have not seen it for many years. "Hardy as this plant is," says Mr. Curtis, in the "Botanical Magazine," "and long as it has been introduced to this country, we do not find it generally in gardens." We attribute this to its having, in a greater degree than many other plants, a partiality for a particular soil. In certain districts, where the soil is stiff and moist, it grows as freely as a weed, and in others is continually going off. Now, in most localities there is a place to be found to suit almost any plant, if due labour is given and attention to replanting in a soil prepared to receive the plants. Watchful attention, and love for the plants, will do wonders in securing the growth of any plant.—T. WEAVER.

TO CORRESPONDENTS.

*** We request that no one will write to the departmental writers of THE COTTAGE GARDENER. It gives them unjustifiable trouble and expense. All communications should be addressed "To the Editor of the Cottage Gardener, 2, Amen Corner, Paternoster Row, London."

ACHIMENES (L. S.).—The following will best suit you for a greenhouse—*Coccinea* and its varieties, *Longiflora major*, *Grandiflora Liepmannii*, *patens*, *candida*, and *splendens*. These we find stand the best. The propagation and management have been several times given, but we will repeat the main points in good time, if not shortly. You may yet try tubers any time during the winter, and keep them dry without shrivelling, and away from frost, until the end of March, and then they will want a little assistance in a hotbed, or under a hand-light, in a warm corner of the greenhouse in April.

PIGEONS (*Agricola*).—Write to Mr. Adkins, Edgbaston, near Birmingham.

GERANIUMS TURNING YELLOW (*A Constant Subscriber*).—We are much obliged for your clearly-written statement; but, judging from our

own practice, we should say that the moderate use of charcoal in the soil and drainage has quite a different effect. An ounce, or two, to a fair-sized pot we should consider moderate, which is the quantity you say you used. We should be led to conclude that alternate dryness and soakings had something to do with the yellowness of your Geraniums. We are too apt to think there is cause and effect when there is really only coincidence.

VARIOUS QUERIES (Early Riser).—Erica Banksia dropping its buds. Has it been lately shifted?—this would cause it—or has it been allowed to get dry in the interior of the ball? or does it stand in a dull place in this dull weather? In either case the remedy is obvious. The general health seems good. To prevent *Cinerarias* blooming now, cut out the flower-stalks, and replot and grow freely. If you can have successions we would not do so, but rather let them flower on, as they are cheering in the dead of winter. *Shrubland Rose Petunia*.—We think the flower sent is right from its petal, but the bright pink was changed to a purple. It seems, however, to have the bright white eye. If the colour is bright pink it is right. *Medimilla Sieboldii* not flowering.—Do not encourage it to do so now in these dark days. Keep it dryish, but not over dry, and just vegetating, during the winter, in a medium temperature about 55°, and in a light position. As the days lengthen, and light increases, give it more generous treatment, and you will probably be rewarded with flowers. *Ericas* flowering twice a year.—Many of these do so at times, especially after such a hot summer as the last, as their growth was early made and matured. It is not, however, often desirable.

ORANGES AND LEMONS (South Wales).—These, on the back wall of a small lean-to greenhouse, will do admirably. In a space eighteen feet long by eleven in height you may plant three plants, your favourite one in the centre. The more light and heat you can give them in such circumstances in summer, the more the plants will thank you. Some time back Mr. Fish gave a full detail of the subject.

VARIOUS QUESTIONS (Greenhorn).—*Verbenas* damping off.—These were struck in pans in August, have been watered lately only when dry, but still the plants next the outside of the pans keep damping off. Are you sure the plants had not been too dry before you watered them? We ask this, because we should have expected the plants to damp in the centre. Young *Verbenas* will not stand drought in the winter, and yet the atmosphere about them must be moving and dryish. If your plants are very thick in the pans, pot off the whole, or a portion, and place them at first in a close place. If not very thick, let them remain as they are, see that they do not want moisture below, scrape off a little of the surface soil, and scatter over it a layer of equal parts heath soil, powdered charcoal, and sand. If even that, in continued dull weather, should absorb much moisture, shake it off, and replace it with fresh. In another season, if you strike as early as August, you should pot off in September. *Fuchsias* straggling in their growth.—You may cut back either now or in spring. Cut down close to the surface of the soil, if you want a strong, fresh shoot, or shoots, next season; but only cut the side branches to the buds nearest the main stem, or merely shorten them considerably, if you want early bloom. See the modes of keeping mentioned lately. Your *Cape Jasmine*, straggling, and that has not flowered—take the chance of what flowers it will give you in spring, after placing it in a hothouse or hotbed; then prune it well back, and let it remain in the hotbed until it has made fresh shoots an inch or two in length; then shake it out of its pots, clear away all the old soil, or nearly so, and replot in sandy peat, with a little fibry loam, and replunge in the bed, after giving it a rather small pot. After the pot is filled with roots, shift again into similar material, only adding more loam, place it in the bed again, and harden it off by degrees. A temperature about 40° to 45° will suit in winter; and if you can place it in a hothouse the following spring, or in a sweet dung hotbed, which is better still, you will get rewarded for all your care, and find that the very attentions you bestow will insensibly change the greenness of your tree into a rich russet mature bronze.

CUTTINGS (One Thousand and One).—Your own practice seems rational enough, but whoever told you that "steam generated" in your "cold pit," was certainly in error. Damp was the cause of "fogging." Cold pits will always be too damp for late autumn cuttings; yet, to get the cuttings rooted they must be kept close so late in the season, that it follows that such cuttings should be either made earlier, or be encouraged with a gentle hotbed. In either case they should be kept close till they form roots. Surely there is no "contradiction" in all this. A good propagator could root buds of roses, and of many other plants, with a leaf and a splice of the wood to them, in a brisk hotbed in the spring; but you had better not waste your time on such nice experiments for awhile, or till you learn the more common and easier ways. We saw some hundreds of *Datura graecilis* struck from single eyes this season.

FLOWER-GARDEN PLAN (B).—We perfectly understand how your garden "looks exceedingly well, notwithstanding its simplicity." It is the best of that class we have seen this season, and you will see that we have engraved it. We are also very much obliged to you for sending it. We want as great a variety as we can get for the series; we require more particularly those which suit such places as are confined, and from 150 to 200 feet in depth, and from 30 to 40 or 50 feet in width, for our suburban villas, &c.

CUTTING-DOWN LAURELS, &c. (Ibid.).—It is by no means necessary to delay this work till July. That is the best time for the general pruning of evergreens; but cutting them back a little, or down close to the ground, may be done any time from November to May, if the weather is mild.

USE OF DECEMBER EGGS.—"In a foot-note to your article on the sale of Mr. Sturgeon's Shanghai fowls, you ask, 'Of what use for sitting purposes are eggs laid in December?' Last year, two of my Silver-spangled Hamburg pullets began to lay about the 1st of December; six of the eggs were put under a hen, and were hatched on the 1st of January, and were reared, and are now healthy fowls. The circumstances under which they were hatched were not particularly favourable; and the only precaution afterwards taken, was to keep the hen and chickens in a common garden frame."—JOHN HARLOW, Moseley, near Birmingham.

SHALLOW HOTBED (Verax).—You must remember that "A Corres-

pondent's" hotbed was probably made during summer, or before the "dark days" had arrived, and that it was enclosed with a brick wall; see page 17. Now, although a foot-deep bed is not the sort of thing to place much reliance on, we have known such a bed serve a temporary purpose—the season being favourable. You have put your questions irrespective of seasons; but we will try our hand on the averages. Such a shallow bed made of dung alone, in July, would last a month; in November, a week; of tan alone, in July, a week or two; mixed tan and leaves, in July, a week or two. To your second query, how best to convey a mild bottom-heat, we say we know of nothing equal to hot water. With plenty of manure and labour, you may, however, do much. If your pit is inside a house, a mixture of dung and leaves nearly three feet deep, with the flue, will provide a nice warmth. Doubtless your Hambro's will ripen.

VINE BORDER (A New Beginner).—We have heard and read of many vine borders, but yours for complication exceeds most of them. We have studied your case for nearly half-an-hour, and cannot confess to an appreciation of the plan. We are no users of composts. We prefer a porous turfy loam, with some coarse manural matters, and plenty of old mortar rubbish, and a border of half-a-yard deep of soil, one-half above the ground level, and you may take all your horse bones, &c. Your plan may be a good one, but we dare not commend it. If you can warm your vine roots, do. Pray favour us with your mode of growing the Strawberry.

UNFRUITFUL APRICOT (J. T. S.).—Root-prune your Apricot rather severely directly, and top-dress the border to induce surface-roots; thin the wood well.

PINE-APPLES (H. Horton).—You do not state the kinds of Pine. The probability is, that they will yet make a spring growth, and show fruit about June or July. This, however, depends much on your atmosphere. A plant disposed to show fruit generally indicates it by a peculiar sturdiness, irrespective of age. If on pulling at a leaf half-way up the stem, and shaking the plant, it appears immovable in the stem, you may soon look for a show. We should say not less than twenty inches of soil will do for them. A plant in a pot will meet with relief within a couple of years, but not so, if planted out. Pines require depth and durability of soil.

YELLOW CALCEOLARIAS (Verax).—You wish for a list of Yellow Calceolarias, distinguishing the shade. Will the one below be useful to you:—*Amplicaula*, fine lemon yellow. *Augustifolia*, pale-lemon. *Flo-ribunda*, free-flowering; pale-yellow. *Kayii*, orange-yellow. *Kentish Hero*, brown-yellow. *Shankleyana*, bronzy-yellow. *Sulphurea splendens*, dwarf; rich, clear yellow. We know a person that has several new varieties of yellow, shrubby Calceolarias, which will be ready to send out in the spring; probably some of them might suit you.

TALL LOBELIAS (A Subscriber from the commencement).—Your remarks on the tall Lobelias are perfectly just. There are great numbers that are not worthy a place in a border. You wish for a list of "really distinct and bright-coloured varieties." The following is one sent by Mr. Appleby, who says they answer to your requirements:—*Aurora*, large; light, bright purple; broad petals. *Buckii*, deep blue, white eye. *Elfrida*, violet-blue. *Fulgens insignis*, *Fulgens ramosa*, bright scarlet. *Fulgens splendida*, bright, deep scarlet. *Queen Victoria*, extra fine; deep crimson-scarlet; very brown petals. *Modesta*, lilac and white. *Purpurea*, purple, white eye. *Violacea*, violet, white eye.

APPLES AND PEARS ON WALL (J. N. Omagh).—These ought not to be nearer than thirty feet to each other. The Cherries not nearer than twenty feet. Your Peaches, Apricots, Nectarines, and Plums, you may leave as planted, at fifteen feet.

SALVIA PATENS.—The same correspondent says—"I have grown *Sabia patens* in the open ground here (north of Ireland), without the slightest protection during winter."

FRUIT-TREES FOR NORTH WALL (J. H.).—We should devote this aspect to Morella Cherries, Gooseberries, and Currants, because on it the two last-named can be easily protected and preserved to a late period. Plums, such as the *Imperatrice* and *Coe's Golden Drop*, will ripen on a north aspect, but not earlier nor better than as standards.

REMOVING VINE BARK (A Vine Grower).—You misquote Mr. Errington. He does not say "scrape off," but "peel off every portion of loose outer bark." In this, we think, he is quite right, for thereby all needless shelter for insects and fungi are removed, which might protect them from the full effects of sulphur applications.

AURICULA FRAME (W. P. B.).—The bottom of Dr. Horner's Auricula frame is closely boarded.

SHANGHAI FOWLS' EGGS (Inquisitor).—The best mode of packing these for travelling is with their small ends downwards, in a strong box, and with plenty of bran or oats between them. Pullets of this breed usually begin to lay when about six months old; if very highly fed, and hatched early in the spring, they will sometimes lay when only five months old. No eggs should be used for hatching if more than a fortnight old; the fresher they are for this purpose the better. We do not know the breed you speak of; we believe it is chiefly from Mr. Punchard's stock.

POULTRY FEEDING (Maybush).—In our experiment with the forty-two fowls, the different kinds of food were given at different times. The rice was boiled, and the greaves softened by soaking in hot water previously to being given. We shall give, some day, a drawing and description of our feeding-box.

THE COUNTRY GENTLEMAN'S COMPANION.—*Martha Thrifty* writes thus:—"I, as an injured party, beg to call your attention to the fact, that your new title to 'THE COTTAGE GARDENER' has been the source of much annoyance to the ladies. It used to be considered that a wife was the country gentleman's best companion. Now-a-days, when their long absence from home is complained of, they hold up THE COTTAGE GARDENER, and provokingly tell us they have another companion, which requires increased attention. And our sons, when pressed by us considerate mothers, to make a prudent choice, and take a companion for life, reply—'Mother, we have done so,' and exultingly hold to our view 'THE COTTAGE GARDENER.' Now, for instance, there is Master John,

who, I think, has for some time been far too fond of horses, dogs, hunting, shooting, fishing, racing, &c., and whom I, with all anxiety natural to a good mother, wish to see settled down in the world, and have accordingly looked pretty sharply out among the daughters of my friends, knowing too, that Master John had a great liking for the Misses Sensible, charming girls, one of whom I should be proud to call my daughter, and when I pressed the subject upon Master John—Oh! Mr. Editor, I thought I should hardly have got over it, he said—'Mother, I don't receive any encouragement from these ladies.' 'Because you do not pay them sufficient attention. I will renew my invitations, and then you will have an opportunity of declaring yourself.' 'Mother,' said he, with a deep sigh, 'the one I love is going to be married to Mr. Foresight, so I have determined not to be again disappointed, but to settle down and take the *Country Gentleman's Companion* for life.' Oh! Mr. Editor, what will become of our ancient house, if Master John, our oldest son, does not marry. Dear Sir, do add something to the title, that will make him wish to have a *living companion*." We consider ourselves the injured party, in having our title so misconstrued. Let our friend Martha tell Master John, that we do not call ourselves *The Country Gentleman's best Companion*, but we ask to rank among the next to her.

SHEEP (K).—Buy them at the nearest fair, and get some farmer to help you with his judgment. They will thrive on pastures which have a clayey soil, though lighter soils are better. Ewes in lamb may be purchased.

IRRIGATING WITH SEWAGE (A Learner).—As you have a tank at each end of your plot, buy a moveable pump, and with this and some open troughs you may convey the sewage to trenches cut in any part, so as to irrigate each crop or bed effectually.

UNFERMENTED SEWAGE (H. Sandford).—There can be no doubt, either in theory or practice, as to its being best used fresh. None of the ammonia is then lost. The objections, and very valid ones, to using farm-yard manure in a fresh state are, that when in such state it prevents a tidy tillage, keeps the soil too hollow, and conveys the seeds of weeds into the soil. Our correspondent would like to have some of the *Potatoes* mentioned by *Leighton* in 1850.

DAHLIAS (A Subscriber).—We cannot name dealers. Any first-rate Florist could supply you.

BEES.—*Mary* says—"Your correspondent, 'Investigator,' inquires whether it ever happens that a stock which has swarmed will swarm again with its young queen, after an interval of some weeks? In answer to this, I beg to refer him to *The Shilling Bee Book*, where Mr. Golding says, 'I once had a swarm in August from a stock which had swarmed early in June.' I have known other instances of this unusual circumstance. I shall feel much obliged if 'Investigator' will kindly inform me whether, in cutting out the queen cells, he found it necessary to take out the combs, or whether merely turning up the hive was sufficient for that purpose? My bees are in a barred box hive."

SHANGHAE FOWLS.—*K*, residing in Lancashire, says "The merits and demerits of Cochinchina fowls have of late been frequently treated of in your columns. But there is one point respecting which, I conclude the experience of the various writers in your pages and my own must differ considerably, and that is their great propensity to sitting. I hatched twelve chickens of this breed on the 30th of March last, three cocks and nine hens. Seven of the hens began to lay between the age of five and six months, and an eighth after it was six months old; the ninth has not yet commenced laying. Most of them laid daily for a month, and at the end of that time all have wanted to sit. Two of them have been allowed to do so; one on Aylesbury ducks' eggs, from which she has brought out a fine brood of six, now ten days old; and the other on her own eggs, and she recently hatched four young ones. But nothing that can be thought of will overcome the propensity to sitting in the others. For the last month two of them have been in this state. Can any of your numerous readers tell me how to manage, for if every hen of this breed after laying twenty-eight or thirty eggs must be indulged in sitting it will be a great drawback upon their value. All my friends in this neighbourhood (North Lancashire) who have these fowls make the same complaint. Respecting their eating, my servant says that they are not large eaters for their size. A friend of mine, in the adjoining town (Preston), says, that his fowls do not cost him on the average 1s. per week, and he has not any beside the purest Cochinchina." We do not find our Shanghai fowls more prone to sit than others. If they should require to sit at this time of the year, we should let them remain on their nests without eggs for three weeks, and then put them into a coop. The broody furor will then have had its natural course, and they would begin to lay again just at the time it is desirable to have eggs for sitting.

WORK ON BOTANY (P. S.).—A cheap and good elementary work is *Henry's Rudiments of Botany*.

ROSE DEVONIENSIS (T—U).—This is quite a modern variety. Any of the great rose-growers will supply it for about two or three shillings, according to the size.

BEES (J. N. William).—Feed your bees immediately with a thick syrup of sugar, honey, and water, until they weigh full twenty pounds. If their food is all gone we fear you have little chance of saving them.

ERRATA.—Page 105, col. 1, line 7 from the bottom, change "Canna India shoots," into "Indian shoots." Second column, fourth line from top, change "created" to "saved."

NAMES OF PLANTS (Mr. R.).—We cannot yet make out your plant from the seed sent, but we will notice it again. (*Killmallockensis*).—Yours is *Physalis alkekengi*. It is a hardy herbaceous plant. It is easily propagated by parting the roots. We should not like to eat the berries, though it is said to be eaten by the Germans and Swiss. It is commonly called the Winter Cherry.

CARNATIONS, defend in inclement weather. **COMPOSTS**, prepare. **CROCUSES**, take up and pot in lumps, to force in pots. **DIG** over borders, and dress all quarters generally. **EDGINGS**, trim. **FIBROUS-ROOTED** perennials and biennials, divide and plant. **FLOWERS** (choice), defend generally from inclement weather. **GRASS**, roll occasionally, if winter be mild. **GRAVEL**, roll and keep orderly. **HAWTHORN**, gather berries and bury in sand, to sow next October. **HEDGES**, plant, and clip deciduous ones. **HYACINTHS**, defend in inclement weather. **LEAVES**, collect for compost. **MULCH** round the roots and stems of shrubs newly planted. **PLANT** shrubs of all kinds. **POTTED PLANTS**, protect in deep frames, &c.; place in hothouse for forcing. **PRIVET**, gather seeds of, and make young shoots into cuttings in bad weather, lay them in damp sand or soil, and set next February. **PRUNE** all shrubs requiring regulation. **PRUNED ROSES**, scrape bark, and wash with lime and soot. **RANUNCULUSES**, defend in bad weather; plant, if mild; seedlings of them require protection. **STAKE** shrubs newly planted, and any others requiring support. **SUCKERS** may be planted as removed during the winter dressing. **TULIPS**, defend in bad weather. **TURF** may be laid in open weather. **UNCOVER** protected plants, and if not dry, place dry materials next them. **WATER** in glasses, change weekly; add a few grains of salt, or five drops of spirit of hartshorn. Buy all your **TREES** and **SHRUBS** forthwith, and put them in ground, preparatory for final planting in February. Think on the **ICE-HEAP**, and let leaves be gathered to cover it. See, also, that the ponds of water from which you get ice are freed from leaves and sticks, &c.

D. BEATON.

GREENHOUSE.

AIR, admit freely when the external temperature is above 35°, especially among hard-wooded plants not desired to have early in bloom. Those growing freely, or in bloom, should have an average temperature at night of 45°. A warm greenhouse should be seldom lower. **AZALEAS** for late blooming, keep cool. Those swelling their buds not below 45°. **BULBS**, well-rooted in pots, place in gentle heat for early blooming; put funnels of paper over the *Hyacinths*, to cause the stems of the early ones to rise freely; keep mice from the successions; few things are better for this than chopped furze. **CALCEOLARIAS**, **CINERARIAS**, **CAMELIAS**, &c., attend to with heat and moisture, according to the time you desire them to be in bloom; the two first will require frequent fumigating. **CHRYSANTHEMUMS**, water freely with manure water. **CLIMBERS**, prune generally, to give light to the plants beneath them. *Passion-flowers* may be pruned back to within a bud of the main shoots. *Tecoma jasminoides* will bloom best on longish, strongish shoots, the smaller, therefore, should be cut out; after the strength is thus moderated, by these flowering profusely, it may be spurred back, like *Passion-flowers*. Train and clean winter-flowering climbers, such as *Kennedy's Maryat*, and various *Tropaeolums*, such as *tuberosum* and *pentaphyllum*; the latter, started in summer, will bloom all the winter, but the best for this purpose in a warm greenhouse, is *Lobbianum*. **EARTH** in pots and borders keep fresh by stirring. **GERANIUMS**, encourage the forwardest, when early blooming is desirable, with plenty of air, and a medium temperature of 45°, giving them plenty of air, and tying them out. *Scarlets*, taken up from flower-beds, and kept in boxes and sheds, keep dry. Keep old *Calceolarias*, so raised, moister. **HEATHS**, keep cool, and give abundance of air in mild clear weather. **HEAT**, by fires, apply when necessary; use a little covering in severe weather in preference to making the fires strong. **IXIAS**, **GLADIOLI**, and the hardier **LILIES**, pot and set in a cold pit, to be protected from frost. **INSECTS**, keep under, by fumigating and scrubbing. **LEAVES**, dirty, wash; decayed, remove. **MIGNONETTE**, take in a few pots now and then. **OXALIS**, give winter-blooming ones, such as *lobata*, plenty of light and water. **POINSETTIA PULCHERRIMA** will make a warm greenhouse gay now for several weeks. **PRIMULA** (Chinese), introduce; water with liquid-manure when it shows the flower-bud; the double-white give a favourable and warm position; as the flower stands well when cut it is valuable for nosegays. **ROSES**, and other **SHRUBS**, introduce for forcing; commence at first with a top temperature of from 45° to 50°; if the bottom-heat is from 5° to 10° higher, all the better. **SALVIA SPLENDENS**, supply liberally with water, and give it a warm corner. *Gesnera zebrina* will still be a good accompaniment, where the average night temperature is 45°. *Salvia gesneriflora* will succeed *Splendens* in the spring. **SUCCULENTS**, keep dry, and *Cactus* especially, except the *Truncatus*, which will now be in bloom; give it a warm position, or the blooms will not open freely. The same may be said as respects position, in the case of *Oranges* opening their bloom. **WATER** seldom; be regulated by temperature, evaporation, and the wants of the plants; when the flower-buds are swelling and opened, give it oftener, and after breakfast, and with the liquid rather higher than the temperature of the house. **TEMPERATURE**, 45° during the day, 40° at night, with 5° to 10° more, at a warm end, or a conservatory, for placing tenderer and forced flowers when first introduced, allowing in each case a rise of 10° or 15° for sun heat. In severe weather, prefer covering, even during the day, to large fires; comparative darkness in a low temperature, for a short time, is preferable to light, and a parched atmosphere. Young plants just potted-off, or in their cutting-pots, suffer often at this season from two opposite causes. First, in the windows of sitting-rooms—the dry air exhausts them, and here, instead of soaking the roots, sponging and sprinkling its foliage, is the preventive. In pits and frames without fire-heat, with all the air you can give, some will damp-off. Avoid everything of a wet or fermenting material against the walls or boarding. Two or three inches thick of wheat straw tied firmly against them will help to keep the inside both warm and dry.

R. FISH.

ORCHID HOUSE.

AERIDES, *Saccolabiums*, and similar plants, keep moderately dry. **AIR**: excepting on very fine, bright, sunny mornings, when the heat of the sun and the fire combined raise the temperature too high, no air will be required this month. **BLOCKS**, plants on, syringe when the sun is likely to shine. **BASKETS** with plants in, that are growing, dip in tepid water two or three times; those not growing dip only once. **BASKETS** (new), make to be ready when wanted. **COCKROACHES**, search for diligently, and destroy; lay poison for them; the best is

CALENDAR FOR DECEMBER.

FLOWER GARDEN.

ANEMONES, defend in bad weather; plant, if mild, for the last time till February. **AUBICULAS**, defend in inclement weather. **BULBS** omitted, may be planted if the weather be mild. (See November).

candle ends crushed and mixed with arsenic—this is a sure destructive agent. HEAT, moderate, to induce rest; day, with sun, 70°; without, 65°; night, 55° to 60°. INSECTS, destroy diligently; one pair destroyed this month will prevent a numerous brood next year. MOISTURE IN THE AIR, supply to plants growing. POT growing plants: several will start this month; do this before new roots are formed. PEAT, procure; choose the most fibrous; the best is found in dry woods, where the Common Brake (*Pteris aquilina*) abounds; the roots of this fern form the best fibrous peat. STANHOPEAS, in baskets, beginning to grow, put into fresh baskets with fresh peat; four inches deep is quite sufficient. WATER at the roots, apply only to growing plants, and that round the edges of the pots. YOUNG SHOOTS, look to, and keep the centre dry, or they will rot.

T. APPLEBY.

PLANT STOVE.

AIR, give on all favourable occasions. ACHIMENES, pot a batch to flower early. AMARYLLIS, pot a portion, and plunge in a moderate tan-pit to flower early. BEGONIAS, to bloom early, repot. CLERODENDRUMS beginning to grow, repot towards the end of the month, place in heat, and water moderately. ERANTHEMUMS, winter-flowering, water freely, and occasionally with liquid-manure. FERNS, repot small plants; reduce the water to old ones; cut down decaying fronds. FRANCISCEA, pot a few, and place in heat, to flower early. GARDENIAS, pot a batch, wash every leaf, and place in dung heat, to start them to grow, and kill insects on them, especially the red spider, the great enemy of Gardenias. GESNERAS showing signs of growth, shake out of old soil, and pot in fresh compost, give little water and moderate heat till next month. GLOXINIAS, treat a few similarly. HOYA BELLA, a new and beautiful species, put in baskets, and train downwards. IXORAS, keep cool, and moderately dry, through the month. LUCULIA GRATTISSIMA, in flower, remove into a greenhouse, to prolong the bloom. LYCOPODS, divide and repot. PASSIFLORA, and other climbers, prune, and tie neatly in. PLANTS TO FORCE, such as *Azuleus*, *Persian Lilacs*, *Rhododendrons*, *Roses*, &c., place in a forcing-house, to bring them on to flower early. ROGERIAS, a genus of winter-blooming plants, should be now showing flowers. SERICOGRAPHIS GHEISBREGHTIANA, another addition to our winter-flowerers, repot, and water freely after the blooms are visible. TAN BEDS, renew, to keep up a good heat through the winter. In every department of the stove, let cleanliness prevail; clear the surface of the pots of moss and lichen; stir up the soil carefully, without injuring the roots; search diligently for insects; keep the walls and floors as dry and clean as possible; remove decaying leaves as soon as they occur; wash pots with plants in that have become green; and let neatness be the general order of the day throughout the month.

T. APPLEBY.

FLORISTS, FLOWERS.

AURICULAS and POLYANTHUSES, protect from severe frost; give air on every fine day; keep as dry as possible without flagging, remove decaying leaves, and stir the surface of the soil occasionally. CALCEOLARIAS: seedlings transplant; seed may yet be sown. CARNATIONS and PICOTEES, shelter from frost, snow, and heavy rains; give air to on fine days, even to pulling off the glass; in wet weather give air by propping up the light behind; water, if very dry; watch for slugs, and destroy them. CINERARIAS, protect from frost; repot seedlings. CHRYSANTHEMUMS, give occasional supplies of liquid-manure to, to bring out the later blossoms. DAHLIAS, examine, cut off any decaying part to the quick; protect from frost. FUCHSIAS, cut off young wood, and keep the plant dry. HOLLYHOCKS may be planted in open weather; mulch with short litter; cuttings pot off, and seedlings transplant. HYACINTHS in beds, shelter from frost, by mulching. *Hyacinths in pots*, place a few in heat, to bloom early; in glasses, wash the roots in pure water, to cleanse off the green slime; give them fresh water in the glasses. TALL LOBELIAS, take up, pot, and pack away in a shed, till they make fresh shoots in March. PINKS, look to after frost, and press the earth to the plants. RANUNCULUS BEDS, prepare. TULIP BEDS, shelter from frost, heavy rains, and snow; finish planting, b. VERBENAS in frames, give abundance of air to; if mildew prevails, dust with sulphur; protect from hard frost; water seldom, and only then when absolutely necessary; pick off decaying leaves. In this month FRESH SOILS may be procured; LEAVES collected; HEAPS of manures, loam, and peat, frequently turn over to sweeten and pulverize.

T. APPLEBY.

ORCHARD.

ALMONDS, plant. APPLES (Espalier), prune, &c.; plant, &c. APRICOTS, plant. BRINE, apply with a scrubbing-brush to stems and branches of fruit-trees, to destroy insects, eggs, and moss. COMPOST, provide. CHERRIES (Wall and Espalier), prune and train; plant. CHESNUTS, plant. CURRANTS, prune; plant. CUTTINGS of Gooseberries and Currants may be planted. ESPALIERS, prune and regulate. FIGS, protect from frost. FILBERTS, plant. FURK the surface around fruit-trees. FRUIT-ROOM, ventilate occasionally, and keep dark. GOOSEBERRIES, plant; prune. LAYERS, plant. LOAM and COMPOST, obtain. MEDLARS, plant. MULBERRIES, plant. MULCH, put around newly-planted trees. NAILS and SHREDS, draw and prepare in bad weather. NECTARINES, plant; prune and train in frosty weather. NAILING, proceed with in cold aspects. PEACHES (See *Nectarines*). PEARS, plant. PLANTING, in general, proceed with. PLUMS, plant; (Wall and Espalier), prune. PRUNING, attend to generally. QUINCES, plant. ROOT-PRUNE where necessary. RASPBERRIES, plant; prune. SERVICES, plant. SNAILS, destroy in their torpid state. STAKE and support trees newly planted. STANDARDS, remove dead and irregular branches from. STATIONS, make. SUCKERS, plant; remove from all fruits. TRAINING, proceed with. TRENCH and prepare borders, &c., for planting. THIN orchard-trees. VINES, plant, prune, and train. WEATHER (bad), provide work for. WALNUTS, plant. WALL-TREES generally, prune and regulate. WALLS, it is a very beneficial plan to paint these by means of a white-washer's brush, with a liquid mixture of 8 lbs. lime,

4 lbs. soot, and 6 lbs. sulphur. It destroys and banishes insects, as well as, by its dark colour, promoting warmth of the wall. The liquid employed, in which to mix the above, should be urine and soap-suds in equal proportions.

Any trees proposed to be regrafted in the spring, may be headed down now, but the stumps of the branches should be left sufficiently long to permit a few inches more to be cut off at the time of grafting.

R. EBRINGTON.

FORCING HOUSE.

AIR, see *Ventilation*. ASPARAGUS, promote succession crops; bottom-heat 70°; plenty of air when up. APRICOTS, see *Peach*. BOTTOM-HEAT, sustain generally about 72° to 76°. CUCUMBERS, top dress, apply liquid-manure and stop, and keep glass clean over head; air heat, 60° to 70°. CHERRIES, (see *Peach*). COVERINGS, apply assiduously, so as to be able to give air frequently. FIRES, use discreetly, to repel frost, to sustain the proper temperature, and to be able to give air rather liberally. FIGS, (see *Peach*). GLASS; wash all roofs. GRAPES, late fruit, fire freely in the day with much air; avoid spilling water in house, and use the scissors once a-week thoroughly. INSECTS, extirpate, now is the time; do not forget the soft-soap, the sulphur, the sponge, and fumigation. KIDNEY-BEANS, pot in five-inch pots, four in a pot; the *Dun's* and *Newington Wonder*; light secure by all means; keep glass clean washed. MUSHROOMS, temperature 50° to 55°; plenty of air moisture. NECTARINE and PEACH in blossom, keep at about 55° by day, at night about 40°; water very sparingly; shake branches gently, to distribute the pollen; stir earth around often. PINES, secure 60° to 70° to fruiters, with plenty of air; bottom-heat, 77° in dung-pits, keep hardy by plenty of air, and good linings; no water until the end of January. ROOTS, protect in all tubs, boxes, pots, &c. SEA-KALE, provide successions; bottom-heat 70°. STRAWBERRIES, introduce about the middle of December, earlier is not safe; begin at 50° in heat, and a bottom-heat 60°. TARRAGON, MINT, SORREL, MARJORAM, &c., introduce to bottom-heat. Let HEAT follow in a ratio to the light, at any period. VENTILATE as freely as you dare at all times. VINES to force, begin at 50°; in blossom, maximum, 70°; keep air moist, and get a warmth in border of 75°; sulphur freely; remember the dreared mildew. WATER, apply always in a tepid state.

R. EBRINGTON.

KITCHEN GARDEN.

ARTICHOKES, dress. ASPARAGUS-BEDS, dress, b.; plant to force; attend that in forcing. BEANS, plant a good main crop the first week in the month, if not done the last week in November. BEETS (Red), dig up and store, b. BORECOLES, full grown, may be taken up with good balls of earth, and planted in any nook or corner, or plot of ground of less value, in open weather. BROCOLIS, treat the same, but lay in deeper, so as to earth up the stems well; lay them in carefully, with their heads towards the north. Thus moving these vegetables gives an opportunity to prepare the quarters they occupied for other important crops; they are thus better enabled to stand the severe weather that may be expected, and, being closer together, they are much more convenient for protection. CABBAGES, plant; earth up. CARDOONS, earth up. CARROTS, store the main crops if not done, and attend to those growing in frames, &c. CAULIFLOWERS, attend to airing in all favourable weather those in frames or under hand-glasses; remove all decayed leaves, and look after slugs. CELERY, earth up, and protect when necessary. COLEWORTS, plant. COMPOSTS, prepare and turn over. CUCUMBERS, attend to those bearing; sow seed towards the end of the month for plants to plant out in the middle of January. DUNG, prepare for hot-beds. EARTHING-UP, attend to. ENDIVE, take up full grown on a dry day, and plant deep and close together at the foot of walls, or other warm dry corners convenient for protection in severe weather. HOESE-RADISH may be dealt with in the same way as directed for the Jerusalem Artichoke. HOT-BEDS, attend to. JERUSALEM ARTICHOKES, give a good top-covering of any rough mulching or garden-refuse, so as to keep out frost, and to enable them to be taken up when required; yet it is well to have a few of the roots stored for fear of snow, or other rough weather, at the very time they are wanted. KIDNEY BEANS, force, e. LEAVES, fallen, collect together. LETTUCES, attend to those advancing in frames on a gentle heat; see that no drip falls into the hearts of the plants, and give all the air the weather will permit to such as are planted in frames for winter protection only. LIQUORICE, dig up. MINT, force. MUSHROOM-BEDS, make; attend to those in production. PARSNIPS, dig up and store, b. PEAS, sow in the open ground of the best early kinds, protecting them from frost, mice, slugs, and birds. PLANTS, to produce seed, attend to, b. POTATOES may be planted in light soils in open weather, and in hot-beds towards the end of the month; examine often the in-door stores. RADISHES and SMALL SALADING, sow in frames, &c. RHUBARB, take up and pot off for forcing, or cover up with pots or tubs and fermenting materials. SEA-KALE, cover up with fermenting materials; fallen leaves are the best materials both for covering up the Sea-kale and Rhubarb. SPINACH, keep clear of weeds, and fallen and decayed leaves. TANSY, force. TARRAGON, force. TRENCH, drain, &c., vacant ground. WEEDING, attend to. Be on the alert of a frosty-looking evening, and COVER UP a little earlier. TURNIPS, any quantity, according to the demand, may be taken up and stored, or packed up tidy in a corner, to be buried in coal-ashes, so as to be come-at-able when required. We always make it a rule, at this season of the year, to store in little or much, according to the appearance of the weather, a dozen or two of *Celery*, and *Endive*, *Brocoli*, or anything else that is likely to be required.

T. WEAVER.

LONDON: Printed by HARRY WOOLDRIDGE, Winchester High-street, in the Parish of Saint Mary Kalendar; and Published by WILLIAM SOMERVILLE ORR, at the Office, No. 2, Amen Corner, in the Parish of Christ Church, City of London.—November 25th, 1852.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last twenty-five years, the average highest and lowest temperatures of these days are 47.1° and 36° respectively. The greatest heat, 57°, occurred on the 2nd in 1835; and the lowest cold, 14°, on the 6th in 1844. During the period 85 days were fine, and on 90 rain fell.

TANSEY-LEAVED MACHÆRANTH.

(*Machæranthera tanacetifolia*.)

THIS is a genus of Composite plants, and belonging to the Syngenesia Superflua of Linnæus. Little is known of it in our gardens. It belongs to the section of the true *Asters*, and was named by Nees Von Esenberg, from *machaira*, a sabre, and *anthera*, the male organs or anthers. The present species was discovered by Dr. Wright, in New Mexico, and from seeds sent by him to the Kew Gardens, it has been ascertained to be a handsome dwarf biennial, with

flowers as large as those of a single China Aster, and much like one; the centre of the flower is yellow, and the ray outside a purplish-blue, but in the bud, the tips of the ray resemble some red thistle just bursting. The leaves look as much like those of the Chamomile as the Tansey. It is a half-trailing, slightly shrubby plant, and will bear exposure in our open borders in summer. *Leaves* alternate, stalkless, slightly downy, cut into numerous, spreading, narrow, toothed segments; these segments become finer on the upper leaves. *Flowers* solitary, and terminating the branches with hemispherical scaly involucre. Florets in the centre, tube-like, and five-toothed. It is figured in the *Botanical Magazine*, t. 4624. B. J.

Propagation and Culture.—It has been stated by Mr. Smith, the curator of the Botanic Garden, Kew, that this novelty is difficult to propagate by cuttings, and that seeds are very sparingly produced. Therefore, the only chance we have of succeeding with it, is to begin very early in the spring, and to give a slight heat to the plant, and as soon as an inch or two of young growth is made, to make cuttings of the shoots directly. There is hardly a plant in this, the very largest order in the vegetable kingdom, that can escape such timely mode of propagation, although there are many of them that defy the art of man to root from cuttings, from the moment the first germ of a flower-bud is formed in the system.

As soon as the young plants are hardened-off; they will grow in any light, rich soil out-of-doors, but in case the seeds should not ripen, a couple of plants should be reserved in pots, and the flowers pinched-off in the bud as fast as they appear. These two plants will furnish a stock of cuttings the following season. Neither the old *Cineraria cruenta*, nor the first *China Aster*, promised so good a chance for garden varieties as this plant. If I were a young gardener, I would not rest until I drove this plant to the verge of a florist's flower. Its very aspect seems to tell as much at first sight. The habit and the leaves seem to speak of carpeting a bed, and the undecided tints of colour speak at once of a wilding got by a chance sport of nature in the wilds of Mexico. Humboldt, however, saw it cultivated there in gardens, although Dr. Wright found it in a state of nature. D. BEATON.

WE have now arrived at the most modern section of our Poultry literature; and we regret that we cannot say that it has kept pace with the improvement which is so decisive in the objects on which it descants.

If any one wishes for a delightful book about fowls, let him buy *Ornamental and Domestic Poultry*, by the Rev. E. S. Dixon. It is not only readable, but most amusing; full of information relative to the history, past and present, of all kinds of poultry, whether useful or only ornamental; sparkling with bright sketches, and even the fragments of practical detail are all touched off artistically. Take this as a specimen:—

“Shortly before the time of hatching arrives, the chickens may be heard to chirp and tap against the walls of their shell. Soon a slight fracture is perceived towards the upper

end, caused by force *from within*. The fracture is continued around the top of the egg, which then opens like a lid, and the little bird struggles into daylight. The tapping which is heard, and which opens the prison doors, is caused by the bill of the included chick: the mother has nothing to do with its liberation, beyond casting the empty shells out of the nest. At the tip of the bill of every new-hatched chick, on the upper surface, a whitish scale will be observed, about the size of a pin's head, but much harder than the bill itself. Had the beak been tipped with iron to force the shell open, it would not have been a stronger proof of creative design than is this minute speck, which acts as so necessary an instrument. In a few days after birth, when it is no longer wanted, it has disappeared; not by falling off, I believe, which would be a waste of valuable material, but by being absorbed and becoming serviceable in strengthening the bony structure, minute as the portion of earthy substance is. And yet some people direct, that as soon as the chick is hatched, this scale should be forced off with the finger nail, because it is injurious!

"All chicks do not get out so easily, but many require a little assistance. The difficulty is, to know when to give it. They often succeed in making the first breach, but appear unable to batter down their dungeon walls any further. A rash attempt to help them by breaking the shell, particularly in a downward direction towards the smaller end, is often followed by a loss of blood, which can ill be spared. It is better to wait awhile and not interfere with any of them, till it is apparent that a part of the brood have been hatched some time, say twelve hours, and that the rest cannot succeed in making their appearance. After such wise delay, it will generally be found that the whole fluid contents of the egg, yolk and all, are taken up into the body of the chick, and that weakness alone has prevented its forcing itself out. The causes of such weakness are various; sometimes insufficient warmth, from the hen having sat on too many eggs; sometimes the original feebleness of the vital spark included in the egg, but most frequently staleness of the eggs employed for incubation. The chances of rearing such chicks are small, but if they get over the first twenty-four hours they may be considered as safe. But all the old wives' nostrums to recover them are to be discarded: the merest drop of ale may be a useful stimulant, but an intoxicated chick is as liable to sprawl about and have the breath trodden out of its body as a fainting one. Peppercorns, gin, rue, and fifty other ways of doctoring, are to be banished afar, together with their subjects, namely—

'All the unaccomplished works of Nature's hand,
Abortive, monstrous, or unkindly mixed,
Embryos, and idiots, eremites, and friars,
Into a Limbo large and broad, since called
The Paradise of Fools, to few unknown.'

"The only thing to be done, is to take them from the hen till she is settled at night, keeping them in the meanwhile as snug and warm as possible. If a clever, kind, gentle-handed little girl could get a crumb of bread down their throats, it would do no harm; but all rough, violent, clumsy manipulation is as bad as the throat-tickling of the hard fingered hangman. Animal heat will be their greatest restorative. At night let them be quietly slipped under their mother; the next morning they will be either as brisk as the rest, or as flat as pancakes and dried biffins."

Next comes before us *Ornamental, Aquatic, and Domestic Fowl, and Game Birds*, by Mr. J. Nolan, of Dublin, long an amateur breeder, and now a merchant of the birds concerning which he writes. It is a volume containing much information, but ill-digested, and containing more information relative to game than to domestic fowls.

Domestic Fowl, their Natural History, Breeding, Rearing, Feeding, and General Management, by Mr. H. D. Richardson, we have before noticed as a very excellent compendium of previously published information; and in its last edition it has been revised by a practical farmer.

Lastly, we have—*Fowls: a plain and familiar Treatise on the principal Breeds*—by Mr. John Baily, the well and favourably known poulterer of Mount Street, Grosvenor Square. This little work is a third edition of his pamphlet on his great pet, "The Dorking Fowl," with the addition of some excellent and useful information relative to other varieties. We have room only for one short extract, and no room to enter into a detail of the reasons why we differ from some of his opinions.

"The real Hambro' fowl is a beautiful bird. There are two sorts, the golden and the silver; they differ in one respect only, the foundation colour of one is white, the other yellow; one description will serve for both. They have bright red double combs; clear hackles, either white or yellow; bodies spotted or pencilled all over with black; taper blue legs, and ample tails. Their carriage is gay and proud; their shape, symmetry, and their appearance is alto-

gether indicative of great cheerfulness, and carrying an air of enjoyment, which always prepossesses in their favour.

"The plumage of the cocks differs somewhat from the hens: they are very little speckled, if at all, except while chickens, when the wings and hinder parts are marked, but this seldom lasts after the first moult. In the silver variety, the cock is almost white, having sometimes a chesnut patch on the wing, and towards the tail some black spots, but these disappear as he gets older. The tail is invariably black, but the sickle feathers are tinged with a redish-white, and in the golden cock they are shaded with a rich bronze or copper. The cock of the golden is red all over, and both have well-defined white deaf ears.

"The great virtue and merit of these fowls are, they are prodigious layers, and this is not brought about by any undue feeding, but it is their nature. They are said never to set, and, as a rule, it is true of them; not one in a thousand deviates from it; but when I lived in Davies-street, I had one at liberty, she stole a nest in a lumber-room, and brought out a brood of chickens.

"They are excellent guards in the country, for when disturbed in their roosting-place, they are the noisiest of the noisy, and nothing but death or liberty will induce them to hold their peace. I think I may say with truth, they lay twice as many eggs as any others.

"In these, as in other breeds, erroneous ideas and names have crept in, some being correct descriptions of the same fowl under another name, but others being imaginative, so far as real Hambro' fowls are concerned.

"The Bolton Bays and Greys, and Chitteprats, are identical with the Hambro'. I have also seen so-called Turkish and Creoles, which were the same.

"As a general rule, it may be observed, no true-bred Hambro' fowl has top-knot, single comb, white legs, any approach to feather on their legs, white tail, or spotted hackle.

"I know no bird that gains so much by change of climate as this does; the British bred are infinitely better than the imported."

In conclusion, we have to observe, that one great deficiency more or less detracts from the value of all the publications we have passed over rapidly in review—they are not original works. They do not place before us facts stored up by the authors, or by their friends; but they retail, again and again, what their predecessors had borrowed before, and that without sufficient knowledge to select ancient truths—always valuable—but republishing them with equally ancient errors. Mr. Baily's volume claims exemption from this condemnation; but this very exemption proves the correctness of our judgment. Mr. Baily has confined himself chiefly to a statement of his personal experience and observation, and the result is a thin duodecimo of 58 pages.

We might proceed to remark further upon the great deficiency of knowledge, often mixed up with the practice of gross ignorance, relative to the diseases of fowls, which are markedly apparent in all the volumes we have enumerated; and added to these deficiencies are most imperfect arrangement, and the absence of good facilitators to reference. These defects are very extensively felt, and, combined with the wide, and more widely-growing, attention now paid to poultry, they have induced several of the best breeders of poultry to contribute the results of their experience, so as to form what we believe will prove to be the most trustworthy work on poultry that has hitherto appeared. It will be published in five or six cheap and highly-illustrated numbers, and the first of those numbers will appear in January next.

COVENT GARDEN.

WE shall now proceed, as we promised last week, to furnish our readers with a list of the fruits which we would recommend for planting, in the manner we spoke of in our last report, and to make such observations on each as may be necessary, and as our limits will admit of. In making the selections we speak of, the main object we have kept in view, is the applicability of the varieties to the generality of soils and situations, there being none of them, so far as our experience goes, which are remarkable, either for delicacy of constitution, or as capricious in their character. It will be observed, that we have avoided many of the popular varieties, such as—Ribston Pippin, and Golden Pippin, and have even introduced some, the very names of which many of our readers have never heard; yet, nevertheless, we feel confidence in what we are doing, because we are writing from experience; and although we are deviating from the beaten track, and not recommending those only, which everybody else recommends, our readers must not be the less relying. We may as well state, that the reason why we do not recommend the sorts we have mentioned, and some others which are well known, is because they are not suited for general cultivation, on account of either requiring peculiar soils, or being naturally of delicate constitution. We shall begin first, with twelve of the best dessert varieties, and then twelve of the best adapted for culinary purposes. In both cases we shall take them as to their season of maturity, beginning with those that are earliest ripe.

1. *Early Harvest*.—This is originally from America, and one of the few which succeed in this country. It is a most delicious early dessert apple, of medium size, and possessing a flavour almost equal to an imported Newtown Pippin. It ripens at the end of July, and beginning of August. The earliest native apples we have, are the Ioanneting and Margaret; but in point of size and flavour, they are not to be compared with the Early Harvest.

2. *Devonshire Quarrenden*.—Who is there, who, in early autumn, has enjoyed the rich, refreshing, vinous juice of the Quarrenden, and would not give it a place in his orchard? It is a strong, free-growing tree, an abundant bearer, and will grow almost anywhere. The fruit is ripe in the first week of August, and continues in use during the whole of that month, and the greater part of September. About the same season, but its first ripening is considerably later, we have the

3. *Summer Golden Pippin*.—A very delicious, early Apple, which ripens in the end of August and beginning of September, but does not keep much over a fortnight. This is a very first-rate variety, and prepares the way for those yellow and firm-fleshed, rich and sugary sorts, which show themselves later in the season, such as

4. *Kerry Pippin*.—This variety is now in pretty general cultivation, and, if we may judge from the quantities which are brought to market, and the prices they fetch, we may safely say it is one which has passed

the ordeal. It is certainly one of the richest-flavoured dessert apples we have. It ripens about the second or third week in September, and lasts till about the middle of October. All we need say in commendation of the Kerry Pippin is, that every one who has not got it should get it.

5. *Scarlet Crofton*.—We are coming now to what may be properly called autumn and winter apples, and we do not know of one better suited to succeed the Kerry than the Scarlet Crofton. It is a medium-sized, flattened fruit, of a peculiarly rich and sugary flavour. It ripens in October, and continues in use till December, with a very valuable property of not becoming mealy.

6. *Court of Wick*.—Although this is now generally grown in all well-assorted gardens, it has not received that attention from the orchardist which it ought. It is one of the best, as well as one of the most beautiful apples in cultivation; and while, by some, it is considered equal in flavour to the Golden Pippin, the tree is both more hardy and healthy than that variety, and will even succeed in soils where some sorts would not grow. It is in use from October to March.

7. *Downton Pippin*.—This is one of the Golden Pippin family, raised by T. A. Knight, Esq., and a most excellent dessert apple. The tree is a healthy, rather robust grower, and an abundant bearer. The fruit is ripe in November, and continues till January.

8. *Golden Reinette*.—Almost everybody knows the Golden Reinette, or ought to know it. It is an old English apple, and one of very fine quality. It is well adapted for orchard planting, as the tree is a vigorous grower and a very abundant bearer, but does not attain the largest size. The fruit is in use from November till April.

9. *Pitmaston Nonpareil*.—A richly flavoured and highly aromatic apple, which was raised by Mr. Williams of Pitmaston. It is in use from December to February.

10. *Wyken Pippin*.—A very fine, tender-fleshed, juicy, and richly flavoured dessert apple, which is in use from December to April. This should be in every collection.

11. *Boston Russet*.—This is another of the few American apples which succeed in this country to any degree of perfection; and it is certainly one of the best of our winter dessert apples. It possesses all the flavour of the Ribston Pippin, and the tree, though not large, is very hardy, and an abundant bearer. It is in use from January to April.

12. *Sturmer Pippin*.—Of all we have as yet enumerated this is, perhaps, the most valuable; not because it is superior in quality to any of the others of its season, but because it keeps longer than any other variety. It is of the richest flavour, being that of the Ribston Pippin and Nonpareil combined; and its season is from February till June.

We have thus completed the circle, and brought our readers round again to the season of the early harvest with which we started. By such judicious modes of planting, Apples of the greatest excellence may be had

throughout the year. It must be borne in mind that some of the varieties we have mentioned are not, from their habits, adapted for the purpose of which we have been treating. It will be necessary, therefore, to have them grafted standard high on strong growing varieties, which make strong straight stems.

We find our space too limited this week for the culinary varieties, but shall continue the subject in our next. We shall now proceed to note our observations in the market during the week. FRUITS still continue plentiful. That fine cooking apple the *Dumelow's Seedling*, or as it is sometimes called *Wellington*, begins to come in and meet with a ready sale at 4s. 6d. to 5s. per bushel. *Winter Pearmain*s have also made their appearance. This is one of the oldest apples on record, and can be traced back to the reign of King John, at which period it was in large cultivation in Norfolk. What would Mr. Knight say to this in support of his theory? We shall speak of this variety next week when noticing the culinary varieties. We have not observed anything new in the way of apples during the week, besides what we noticed in our last. In PEARS there are some very fine *Glout Morceau* and *Passe Colmar*, together with a few *Nelis d'Hiver*, but we shall have occasion to speak of these when giving our list of select varieties for orchard planting. The prices which these are making are from 3s. to 4s. per dozen.

In VEGETABLES there is no scarcity, notwithstanding the great damage which was done by the recent high tides in the garden-grounds about Fulham. One of the largest cultivators informed us a cheque for £500 would not cover his loss. His men were actually navigating the grounds in boats.

PLANTS AND FLOWERS are much of the same description as have been in the market for some two or three weeks past, consequently we need not enumerate them. But, for the information and gratification of our lady readers, we must record the construction of a very beautiful *Bouquet*. The centre was formed of a very fine Double White Camellia, round which were set, in a concentric circle, a Double White Camellia and a cluster of Scarlet Geraniums alternately, five of each; between each White Camellia there were three flowers in a cluster of a very beautiful azure blue Cineraria, of a peculiarly rich and lustrous hue; the whole was fringed round with fronds of some small-growing fern, and encircling these a margin of lace paper. It was the most beautiful bouquet in the market.—H.

GOSSIP.

EAST, West, North, and South, we are right glad to find that *Poultry Exhibitions* are being established. We have before us prospectuses for one in Wales, at *Hay*, on the 16th of December; for one at *Salisbury*, on the 13th of the same month; for one at *Hythe*, in Kent, but the day not fixed; and for one at *Dublin*, on the 8th and 9th. We repeat, we are right glad of this, for it is for the encouragement of a species of stock that may, and ought to be found around every cottage, even

in greater perfection, than around the farm-house and the mansion. But, whilst we rejoice over this extension of Poultry Shows, we would strongly protest against the abuse of them. We have no idea of their being held for mere gain to the parties establishing them, and it is only a still worse feature, if that gain is intended to be obtained by the sale of eatables and drinkables by some neighbouring innkeeper. We yield to no one in the desire to have a metropolitan show, but we do not recognise, as worthy of such a character, either that at Hitchin, or the proposed one at Kennington Oval. We are led to suspect that the latter has the gain we deprecate for its object, and at all events, the originators of both the shows in question, took not into consideration, before they issued their Prospectuses, either the welfare of the poultry, or the interests of the exhibitors. Who that has a just regard for his fowls, will send them from home for a week, five days of which they are to be penned up at the Exhibition? We know of more than one of the best breeders, who would not, on this account, send them to Hitchin, and we know of a still greater number who will withhold their specimens from the Kennington Oval, on the same account. They have acted wisely for their own interests, and humanely for their fowls, by so doing, and we hope that no future exhibition of them will be kept open for more than two days.

We are informed that *Lord Calthorpe's Small Garden Tenants*, near Birmingham, about 150 in number, have formed themselves into a Horticultural Society, and intend to have a show of flowers and vegetables, and we hope fruit is to be included, twice a-year. We shall be glad to aid this and all such societies.

A subscription for *Professor Von Eisenbeck*, whose penury and distress we mentioned in our last number, has been opened, and a remittance already forwarded to him to rescue him from immediate want. Any donation, however small, may be sent to Mr. Edward Newman, Devonshire Street, Bishopsgate.

As long since as 1811 a plant was introduced from North America, that had been still earlier known to the Canadian boatmen as the *Pomme de Prairie* (the Apple of the Prairies, or Plains). They eat its roots, either boiled or raw, these roots being nutritious and insipid, but of a solid texture, and not among the most easily digested foods. To botanists the plant is known as *Psoralea esculenta*. Another recent attempt has been made to introduce it into cultivation as a substitute for the Potato, but we fear that it will not succeed in any available mode. We speak of it as another attempt, because a very few years since its culture was tried in England; and the present attempt is being made in France by M. L. Picquot, No. 11, Rue Guy-Labrosse, Paris, who has called the plant *Picquotiane*.

The following is a list of the *Horticultural and Poultry Shows* of which we are at present aware. We shall be obliged by any of our readers sending us

additions to the list, and giving the address of the Secretaries.

HORTICULTURAL SHOWS.

CALEDONIAN (Inverleith Row), Edinburgh, Dec. 2.
LONDON FLORICULTURAL (Exeter Hall, Strand), Dec. 14+.
SOUTH LONDON (ROYAL), Dec. 9+, 16.

POULTRY SHOWS.

BIRMINGHAM AND MIDLAND COUNTIES, 14th, 15th, 16th, and 17th December.
BRISTOL AGRICULTURAL, December 7th, 8th, and 9th. (Sec. James Marmont.)
CORNWALL (PENZANCE), January 10th, and 11th. (Secs. Rev. W. W. Wingfield, Gulval Vicarage, and E. H. Rodd, Esq.)
HONITON, January 12th. (Sec. H. K. Venn.)
SALISBURY AND WESTERN COUNTIES, December 13. (Sec. T. Pain, Esq.)
WINCHESTER, December 1st. (Secs. G. W. Johnson and J. Colson.)

† For seedlings only.

PINE-CULTURE: THE HAMILTONIAN SYSTEM.

(Continued from page 122.)

WE will now look over Mr. Hamilton's notes, his book, &c., to see if anything has been omitted, or if anything material can be added. Our remarks must, of necessity, assume a desultory character; but they will not be without their use. We will discuss the following heads, alphabetically arranged to facilitate reference: anything which may occur afterwards may form an appendix:—*Atmospheric moisture, Bottom-heat, Composts, Disrooting, Errors, Foliage, Kinds, Longevity, Main principles, Moisture, Old stools, Planting out, Pipes, Root-culture, Recipes, Ripening, Soil, Structures, Suckers, Syringing, Temperature, Ventilation, Watering.* It will, as we think, be far better thus to examine principles, than to give a mere detail of practice, however sound. The essentials once fixed in the mind, a sound practice must necessarily follow.

ATMOSPHERIC MOISTURE.—Here we have one of the most important of all the headings. No plan of Pine-culture can succeed which does not provide a liberal amount. Exceptions there may be at such periods as that of the ripening, but they can be only in degree, and through the successive character of the fruit, not readily practicable. But it is worthy of remark, that some respectable pine-growers think that Mr. Hamilton, in his ardour to produce a vast amount of fruit from a narrow compass of glass, has ridden his hobby a little too hard as to air-moisture in his winter management. We do hope for pardon from Mr. H. whilst we, as a duty, observe, that as a close, warm, and damp atmosphere doubtless favours the enlargement of the Pine, it in like measure favours the enlargement of the crown; and a large crown is neither admired by the table-decker, nor by the pine-purchaser. We would here beg to interpose a hint, and that is, that with no class of plants with which we are acquainted, can the relation of light, heat, and moisture, be a matter of indifference. Winter in Britain is dull, if not dark; therefore, the high-forcing principle is not Nature's way of Pine-culture. Doubtless, we may take some liberties; but caution is requisite; and common sense, though not very romantic, is sometimes exceedingly useful as a guide in difficulties. We say, therefore, so manage your system as that you can at any time supply any amount of atmospheric moisture, and as speedily remove it if needs be; but we must pass briefly to other main points.

BOTTOM-HEAT.—What fearful reminiscences may this very heading bring to the memory of every King of

Spades whose hair has become bleached in the service! How many root burnings, as well as heart burnings, may be called to remembrance? Mr. H. says (p. 55), "Newly potted plants will be benefited by a heat of about 90° for two or three weeks; after which time it may fall to 85° max. and 80° min.; but in the winter 75° will be sufficient for successions. The bottom-heat required for those plants which are to produce several fruits from the same plants ought to be as equable as possible, at a medium of about 80°, and not to fluctuate more than 3° above or below. However, I have known a plant to swell well in the summer in a bottom-heat of 70°; but in winter, when the superincumbent air is kept cooler, the plants that are swelling their fruits will make but little progress except the bottom-heat be about 80°." We may here caution young beginners against the erroneous idea of going a-head by means of extreme bottom-heats: we advise them not to exceed 85° on any account, until they quite understand the habits of the Pine. We saw some of the finest grown Pines in England, this summer, at Alnwick Castle gardens, the seat of his Grace of Northumberland; gardens kept in capital order by Mr. Pillars, the head gardener. The bottom-heat to these Pines could not have been above 75°, and the pots only half plunged, Mr. P. preferring to depend on a pot full of robust roots, to any extra attempts at stimulating the vital action of the plants.

COMPOSTS.—At p. 7, Mr. H. says, "With regard to rich composts, I mean not to dispute their efficiency; I can assure the public, however, that the Pine will flourish well without them if the system of root and atmospheric moisture here recommended be adhered to: water and air, there can be little doubt, constitute the principal food of the Pine-apple." These are strong views, and no doubt, in the main, correct; but it is well known that some of our best pine-growers use liquid-manure, and this we think by far the best form of manuring; for the admixture of manurial matters in the soil has a tendency to hasten the decomposition of the organic matter; and we do think that on the long preservation of this depends, in a great degree, that longevity in the roots which Mr. H. takes as the basis of his system. See heading "*Longevity.*" Mr. H. has, since writing his very useful little book, stated to me by letter, that he considers a good loam, rich in vegetable fibre, complete in itself for the culture of the Pine; and we recommend the opinion to our readers.

DISROOTING.—This, about which so much fuss was made in our laddish days, is now entirely repudiated by all good gardeners, and is only justifiable when plants have received abuses, injuring or destroying their roots; or in case the soil in their pots has become what is technically termed "soured." For further notice, see "*Longevity.*"

ERRORS.—We merely take this in its course to direct attention to one or two which have somehow crept into our remarks; they will be corrected in the conclusion.

FOLIAGE.—Those who watch the evidence in this Pine case will remember Mr. H.'s dry way of defending the poor unoffending foliage. "Be as careful," he says, "of cutting the foliage as you would of cutting your corns." This language, although not remarkable for dignity, is highly emphatic. At p. 63 of his unmistakable little book he says, "No destroying nor shortening healthy leaves," &c. Would not the late Mr. Knight, of Downton, have rejoiced to find that his deep diving into Nature's secrets had not been in vain; that the very class of men who were best able to appreciate high principles (and, perhaps, least fitted to seize them at one period through the giant-like tyranny of that hard slave-driver, prescription) had entered into his labours. Let then, we say, no man cut away a leaf of a Pine until he can show a sound reason (not fancy) for so doing. Mr. H.

very valiantly contends for the astounding longevity of the Pine roots: why did he not say that the foliage was barely second to them in that capacity? Those who desire to look further into this matter may just refer to pages 37, 64, and "Address," p. 6, of Mr. H.'s edition of 1845.

KINDS.—There are, perhaps, some sixty varieties or more in this country, but the principal kinds grown are the Providence, Queen, Enville, Jamaica, and Cayenne. Mr. Hamilton's planting-out system has been principally confined to the Jamaicas, Queens, and Providences; though, we think, he has not cultivated the last to the extent of the two former. He says, "All the Queens, except the old variety, are well adapted to my system. The old Queen is apt to breed too many suckers." In another place he says, "I like the Queens best for quantity of fruit." What the Cayennes may prove under this system is not well decided; but it must be kept in mind that the Jamaica is the most valuable as winter fruit; the Queens then become insipid.

LONGEVITY.—It was formerly considered that the roots of the Pine possessed no vitality worth consideration beyond a year or two; but the fact was, gardeners generally contrived to shorten the days of the roots by bad culture. Mr. H. says (p. 6, 2nd edit.), "It has, however, been established, by the results of many years practice at Thornfield, that one Pine plant is capable of producing one or more fruit annually for any period of time." Again, p. 49, "I had remarked that all the largest fruit, but more particularly the Enville and Queens, were produced from those plants which had been the longest potted previous to fruiting." Mr. G. Jennings, of Knowsley, the seat of Earl Derby, and Mr. Fleming, of Trentham, have, he says, adopted his ideas; Mr. J. has produced splendid results, and Mr. F., it seems, has, in a public print, pronounced Hamilton's system to be the best; this mode of culture, as before observed, being based principally on the longevity of the roots. There can be no question, it appears, that those minute fibres, scarcely visible, and which ramify with age in all directions, penetrating drainage materials, and every lump of turf or soil, possess vast absorbing powers, and that of a *continuous* character, if totally undisturbed. These were despised in former times; our old cultivators could only recognise those lusty white roots which the Pine makes up the stem, and to obtain which, disrooting and other tricks were had recourse to. Those who understand the culture of Orchids will very well understand the position of this question. We do not expect to find our friend Appleby disrooting and leaf-stripping his huge specimen Cattleyas every year, unless it be to make a five pound plant into a ten-pounder, by cutting ten slices at a pound each.

MAIN PRINCIPLES.—These, in the abstract, may be thus summed up:—1st. A secured air-heat adapted to the season: summer, 75° to 85°; winter, 60° to 70°; other periods about intermediate, principally ruled by the amount of light. 2nd. A certain and little fluctuating bottom-heat, bearing a close relation to the air-heat, in summer about 84°, winter about 75°; other periods principally graduated according to the demand on the foliage through light and heat. 3rd. Atmospheric moisture at all times in proportion to the amount of heat. 4th. A liberal ventilation without sudden checks, on principle for the purification of the air, and as an expedient to reduce extreme heats. Lastly, undisturbed root action, in a proper and long-enduring medium. Now this is simply an epitome of all the rest, and to knowing pine-growers may seem superfluous; but as these papers profess to set the matter on a plain footing to a rising generation of pine-men, we feel that the matter cannot be set in too strong a light.

MOISTURE.—Here we have air moisture, and root moisture; two very different affairs. The former can

hardly be supplied in a too liberal way by any of the ordinary means, provided heat and a free ventilation be concomitants. As to root moisture, little is needed by the Hamiltonian mode. Mr. H. writes thus as to an inquiry about watering—"I have watered at the root twice this summer." It must be observed here that the plants are out of pots; their immoveable fibres seizing on and investing all kinds of material in the bed, soil, turfy matters, and even, no doubt, the very stones, debris, &c., &c., attached to which they have a proper feeding ground, an exemption from dangerous extremes, and, doubtless, collect food continually from the gaseous matters by which they are surrounded; the latter brought into play by heat and moisture.

OLD STOOLS.—Mr. H. is all for planting clean stools, if to be had, in preference to young plants, unless the latter are exceedingly strong. He, however, shows that, although Mr. Knight, of Downton, used old stools, that they were in error in totally disrooting or shaking the soil from the roots; "by which practice," he says, "I have discovered the plants will frequently make a long growth before they fruit." Our readers will here see the importance of planting such stools out without disturbance. If, he adds, they cannot be had with roots and balls, there need be no hesitation in planting them without at once into the compost, where, if handled according to the directions in his book, he will guarantee them to produce first-rate fruit the first year. He adds, "They may be planted at any time."

PLANTING OUT.—This heading is almost a repetition of the former. We will, nevertheless, take this opportunity to suggest attention to the modes described in an earlier paper, viz., that twenty inches of soil is enough, and that the pipes be covered with broken bricks three inches, also three inches between; the pipes will, consequently, be fairly imbedded in bricks or rubble of some kind. And here, one remark. Any one about to commence might fancy the soil would get too dry without some provision for water; but such is not the case it appears: Mr. H. solidly affirms this. Indeed, the following extract from a recent letter will show how this stands: "You seem surprised about the 'Chamber' affair. I have dispensed with them everywhere, or nearly so. I have proved the beneficial effects of covering the pipes with rubble (instead of chambering) for twenty years, and never found any inconvenience from the soil getting caked or dry. I should be cautious of laying anything that is a non-conductor between the rubble and the soil. The rubble at the top may be covered with rough gravel, the fine sifted out."

In another paper we shall probably finish the Hamiltonian system. R. ERRINGTON.

RULBS.

(Continued from page 142.)

Alströmeria Hookeriana, alias *rosea*.—This is a beautiful dwarf species, and one of the hardiest of them, keeps its leaves the whole winter in the open border, unless the winter is very hard; and if the tops get killed it is the first of them which is above ground in the spring. It will grow in the very richest kitchen-garden soil; but the front of a vinery, where the border is well drained, is the place it likes best. It is also a good pot-plant, as the leaves and flower-stems are more rigid than any of the rest—besides being dwarf, like *pulchra*. The colour is difficult to describe: *rosea* was a bad name for it, as one-half of the flower is not rose colour; the points of the petals are greenish, then rosy, the bottom of the upper or back petals are light and full of streaks and speckles, with a shade of yellow between the white and rosy parts. It will not cross with *peregrina*, *psittacina*, or *aurea*.

A. peregrina (the Foreigner).—This is the oldest of

the genus under cultivation. It was gathered along with a few more of them by a Frenchman named *Feuillet*, who first introduced them. *Linnæus* named them for the Frenchman, and founded the genus on *peregrina*, but, by a misprint, it is called "*pelegrina*," in *Feuillet's* book; and in the *Cottage Gardeners' Dictionary*; also in every list of them, but one, that has appeared in the old or new world from that day to this. Dr. Herbert corrected the error, however, in 1837. *Peregrina* means "a foreign lady," and it is evident that *Linnæus*, who was fond of joking, gave a feminine termination to Baron *Alströmer's* name, purposely to suit *peregrina*. It is one of the best pot-plants among them, and is hardy enough to live in a border or cold pit, if the border is slightly covered during frost. There is a garden variety of it with white flowers, which does better in a pot, and *Cumming* found a greenish-white variety of it near *Valparaiso*; still it is not easy to get it to cross with others, and the white one does not always come true from seeds.

A. psittacina (Parrot-like).—This is the next tallest and hardiest after *aurea*, and will grow and flower in the open border in any good garden soil. The flowers are dull red, with green tips and black spots. This came out in 1829.

A. pulchella (Pretty).—Orange and red, approaching to scarlet. For many years this was considered a distinct species, and, as such, it was figured in all the Magazines; but now it must fall into *Van Houtte's* Ghent varieties along with another called *Simsii* or *Simsiana*. They are all from a common type—*hæmantha*, and any one may run them into endless varieties. Since I wrote about *hæmantha* (page 142), I have learned that *M. Van Houtte* denies a hybrid origin to his seedlings, but that he had them from wild seeds—which only proves that the seeds were gathered in South Chili, where *Pöppig* states that he found *hæmantha* in meadows near *Antuco*, running into all shades of red, orange, lemon and white. Another, called *pilosa* in the "*Botanical Register*," is one of them. All these varieties make a gorgeous bed planted together, and are as easily managed as so many common tulips or hyacinths, only that the roots ought to be taken up every other year to prevent their going too deep in the bed.

A. pulchra (Fair).—This is the last in our enumeration of them; it was first figured in the *Botanical Magazine*. It is called *tricolor*, in *Hooker's* Exotic Flora, and *Flos Martini*, in the *Botanical Register*. *Cumming* found it near *Valparaiso*, and it appears to have a great range in Chili, according to the other travellers. When I was collecting the species, many years ago, I found two or three seedlings of this at *Mr. Loddige's* Nursery, at *Hackney*; they were a dirty white, with green tips, and not worth much, but proving how much they are given to sport. *Tricolor* is a better name than the true one, but it has four distinct colours, if not five—a white or light ground, streaked with purple, red and green tips, with a dash of yellow across the petals. It is quite as hardy as the rest of them, and is well adapted for pot-culture. I once had a beautiful bed of them, a circle, planted thus—a large mass of *aurea* in the centre, then a row of *psittacina*, round that *hæmantha*, and some of *pulchra*, and *peregrina*, in one row, for want of a good stock of them, with a border of *Hookeriana*; this bed I afterwards turned into a basket-form, by planting a row of *Bomarea acutifolia*, and *hirtella*, or *ovata*, as some call it, quite round the sides; the bed was three feet deep, and nearly one-half of quite rotten leaf-mould, with a soft yellow loam. The two *Bomareas* grew ten to twelve feet in this, and were trained round and round, and at a height of eighteen inches, on sticks with a handle of hazel rod

across, on which *acutifolia* was trained from both ends. This bed was much admired, but now, by using the best of the Ghent seedlings, along with *aurea* and *psittacina* in the middle, a splendid bed, of any shape, might be made much easier, and I can vouch for it, that if it was hedged with these twining *Bomareas*, planted also eighteen or thirty inches, so as to get a thick mass of them, they would much improve the bed, and be in character too, besides the novelty of the thing; for I am not aware of any one else having ever used them so. I may remark, that almost all the *Alströmerias* are natives of Chili, and that out of forty *Bomareas* described, none were found in the whole of Chili, but two species. The rest are natives of Peru, and northwards into Guatemala and Mexico.

Amaryllis.—Since this genus was printed for the *Cottage Gardeners' Dictionary*, strange relations respecting it have appeared, which overthrow both Dr. Herbert's arrangements, and that by Dr. Lindley, in the *Vegetable Kingdom*. The greatest amount of practical knowledge on one side, and consummate philosophy on both sides, were not sufficient to bear the natural test of a true arrangement. In the *Amaryllidaceæ*, the greatest point of difference by which *Amaryllis*, and other allied genera are kept asunder, is a solid flower-stalk, or a hollow one. So many genera have the flower-stalk hollow, or pipy, and so many the reverse. According to Dr. Herbert's ideas, a bulb with a solid flower-stalk or scape, could no more be crossed with one having the scape hollow, than with "an oak-tree."

In the *Vegetable Kingdom*, the true *Amaryllids* are also divided into two sections, the point of difference being the cup or coronet, peculiar to many of them, as the cup inside the flower of a *Narcissus*. All *Amaryllids* having this cup in the flower are in one division, and those of them wanting the cup in the other. Two very simple and convenient arrangements, but they are not natural, neither are the genera in them placed according to their natural affinity. In both, *Amaryllis* is placed far from *Vallota*, and in both, *Vallota* is kept much asunder from *Brunsvigia*, yet the three ought to stand side-by-side, and be followed by *Cyrtanthus*. Dr. Herbert could not cross one species of *Brunsvigia* (*multiflora*) with *Amaryllis*, therefore, he thought *Brunsvigia* might "yet be upheld." But in New South Wales, where all the *Brunsvigias* and *Amaryllises* cross freely, the cross seedlings from *Brunsvigia multiflora* are the most showy of all, as we might expect. The gentleman who effected this cross with whom the plants first flowered in 1847, tells us (*Gardeners' Chronicle*, 1850, 470), that as many as from twenty to forty flowers were on a single scape, and that the "colour is generally like that of *Passiflora kermesina*." And at home I have put the union of *Vallota*, *Cyrtanthus*, and *Brunsvigia Josephine*, beyond a doubt. If Dr. Herbert was alive, he would be the first to acknowledge the necessity for re-arranging of the genera afresh, and this explanation was necessary at the outset, in order to remove doubts that might naturally be entertained against such and such crosses as I shall suggest here and there in these papers on bulbs. I have no wish to change a single name; it is more convenient to hold on as we are, as we do with *Azalea*, *Rhodora*, and *Rhododendron*. All that I claim is, a fair hearing, because I have now no means of pushing such experiments myself.

Amaryllis Belladonna.—This is the best known of all the family; and whatever we may think of the soil in which it is found growing at the Cape, there is no doubt but it likes a good rich soil and an open air treatment in this country. I never saw it growing in a pot half so finely and so vigorously as it does in the open air. Miller's compost for it is as good as any that has been tried since; at two feet deep, after draining the border,

he mixed a quantity of rotten dung; after that he put a foot of rich garden loam, planted his bulbs, and used a lighter soil on the top, the bulbs standing six inches deep. We have seen lately how beautifully they get it to flower at Claremont under similar treatment, and a change every sixth year. I have also seen it flowering well with the bulbs nearly out of the ground, in a very rich border. It increases fast from off-set bulbs, but does not seed freely, or but very seldom in this country. In Australia it seeds freely enough, and the cross seedlings from it there would be a great acquisition in this country, particularly the crosses from the pollen of *Brunsvigia multiflora*; and there is no reason why it should not sport there as *Hippeastrum* does here. *Belladonnas*, and all other bulbs which grow in winter and rest in summer should not be planted in *mixed* borders, nor where the roots of large trees or bushes can reach; the latter will suck away the goodness from the soil; and growing plants require water in summer; and these *Amaryllises* are better in the dry while they are at rest. There are two varieties, one of them paler; and the third species mentioned in the *Dictionary*, *Blanda*, is not in any public collection in this country, as far as I can learn. When I come to the other sections of the genus, I shall speak of the best mode of treating a whole collection of them; but, as they are now pushing out of the ground, I may remark generally, that they require air constantly, and large doses of water from the time the leaf is two inches long; and if they are in pots it is better to water them from below by a saucer full of water, now and then, but not constantly; say as much as the soil can take up in a couple of days; then take away the saucer for ten days or a fortnight.

There is a scarce little bulb, called *Cyrtanthus uniflorus*, *Gastrenama clavatum*, and other names. It is a true *Amaryllis*, and so are all the *Cyrtanthus Brunsvigias*; and there is little doubt but *Strumaria* and *Hessea* are also true *Amaryllises*—at any rate they require the above treatment at this season, as well as all other half-hardy bulbs that grow in winter.

ANDROCYMBIUM.—There are three species of this little-known genus in our *Dictionary*, but they are not worth while for their beauty, only as botanical sections, or curiosities; that they require sometimes to illustrate lectures and so forth. Their flowers are small, and dull, greenish white.

ANISANTHUS (see *Antholyza*) from which Sweet divided them upon grounds not now recognised by botanists.

ANTHERICUM is on any list, but there are no bulbs in it, and therefore I shall pass it, although botanists make it a section of the lilies; at best they are only *Asphodels*.

D. BEATON.

(To be continued.)

VIOLETS.

IN this age of glitter, it is something to find that *worth*, however retiring, is not always passed by and forgotten. The *brilliant* rivets the attention, and affords full play to a buoyant imagination. The *good* is more securely enshrined in the recesses of our warmest affections. Insensible though the world be to *merit*, I believe it is hardly so black a transgressor as many aspirants for distinction would have us believe. But to win the approbation of the world the merit must be *real*—no plated, gilded thing will long pass muster. And, again, the *merit* must be free from alloy, not associated with the impure or the revolting. Then we will freely own that the greatest worth is not always conjoined with the greatest show, and that there are many bright deeds, and many bright things in this world of ours, which are but little noticed by a dreamy philosophy.

Would any reader enjoy a quiet insight into men

and things, let him, in an hour's leisure, glance over the advertising columns of a daily newspaper, or even of those connected with our own humble serial. What a satire at times upon vanity and upwardism! What an unfolding, in general, of prevailing wants, tastes, and aspirations; and, above all, what joyous hopes infused, frequently, for the future. Advertisements will appear just as long as they suit a purpose. Between the line of the beautiful in nature, and the appreciation of the lovely in morals, there is a close connection. Every advertisement, therefore, respecting the gorgeous in flowers, speaks of a refining influence healthily spreading. Every statement announcing where *superb violets* are to be procured, declares not only that the same bettering influence is being felt by the humblest in society, but also, that if not the *already* and the *now*, the period is *nearing*, when true worth, however retiring, whether among plants or men, shall receive its due meed of approbation. Who can forget emotions of the past, associated with a single bloom of the lowly *violet*? Who has traversed the brakes and hedge-banks of society without discovering there, again and again, many of the noblest virtues that adorn humanity?

Several inquiries having lately been made on the general management of these much-prized plants, our Captain Editor has wished me to have "my say" on the subject of *violets*, although I have, in one of our earlier volumes, already noted the main points of management. Referring back might not, however, suit some subscribers, and, as at present I cannot lay hands upon the paper myself, readers will have the advantage of any changes of practice that have been suggested since then. The kinds or varieties will be mentioned in rotation, according to the estimate formed of them, and their early autumn, winter, and spring blooming.

1. NEAPOLITAN VIOLET.—This I still consider to be worthy of a first place, both on account of the *size* and *sweetness* of its lilac flowers. There is one disadvantage connected with it, namely, that it seldom does any good out-of-doors, unless in a very dry and sheltered situation, and even there they will be late. A conservatory, or a glass-covered pit or frame is the place for it in winter. For this purpose young plants are best.

Propagation. This is effected by runners and divisions. First. *By Runners.*—These, if wanted, may be allowed to grow in spring, *but at no other time.* They may be cut off when three inches in length, and inserted in sandy soil, under handlights, on a slight hotbed in March and April. When well rooted they should be planted out in a nice mellow border, about eight inches apart. Second. *By Division.*—This mode involves least trouble, and I think it is the better of the two. Take the plants that have done flowering in April or May, and tear them to pieces with the hand; one plant may thus be made into a good number, each supplied with a nice crown of leaves and roots. Plant these out as mentioned above for the cuttings, giving them from six to eight inches from plant to plant.

Summer treatment.—Almost all the success depends upon this. The *soil* should be mellow, open, and well drained, enriched with a fair proportion of rotten dung, or leaf mould, and if the soil is very adhesive, a good proportion of road or drift sand. The soil should also be frequently stirred after planting. *Waterings* must be duly attended to, and, if a vestige of red spider appear, the plants must be well drenched with soot and sulphur. *Shadings* will be required at first, but as soon as the plants are taking free hold of the soil they must gradually be exposed to every ray of sunshine. Every *weed* will tell against success, because it will prove that neither cleanliness nor stirring the soil has been attended to. Every runner *must* be removed as soon as it appears. Unless produced *very early* in the season, not one

of them will produce anything but leaves during the following winter and spring. This is a first and most essential point of management. Culture must be directed to obtaining strong well-matured heads or crowns; every runner, after a certain size, will be alike a *shader* and a *robber*. When first planted out, and root action is desirable, they need not be nipped too closely at first, but, after free growth is proceeding, every weed should be looked upon as an intruder.

Winter management.—In October they should be taken up and potted, or placed in a bed to be covered by glass. But why not cover them where they are, and thus save labour—if the bed was well prepared at first I do not see why the plants should be moved? The first essential for such saving mode would be the securing of the glass not further than six or eight inches from the plants. But even then, when I tried this mode, I found it was no saving in the end. For instance, the ground was apt to be too wet, and thus the flowers were likely to damp in winter. Both slugs and worms were prone to have their colonies, and then woe betide the beauty of the flowers; and besides, leaves were likely to be more abundant than blooms. When transplanted, on the other hand, though raised carefully in balls, a check was given to the growing principle, just enough and no more than to give a hint to the flower-buds to show themselves; and by the time the buds swelled, the roots were spreading in the *fresh* soil, and thus catering for strength of flower-stalk and size of blossom. In planting in the flowering beds, one of two modes may be adopted according to circumstances. First, where the situation is damp and cold: here it is advisable to raise the bottom of the bed one foot above the surface-soil, either by faggots, old wood, clinkers, stones, or even common soil—above this, if the bloom is wanted early, it will be advisable to have a slight hotbed, one foot in thickness, at least, and over that three inches of rotten dung, or leaf mould, made firm, and over all, eight or nine inches of sandy loam, rather rich and rather dry. When the situation is warm and dry, the soil being sandy, resting on gravel, chalk, or porous rock, then any position in the garden facing the south, or south-west, will answer admirably. A little leaf mould may be added, the soil be well stirred and aerated before planting, and if at all wet or exhausted, a few barrowsful of good, fresh soil may be added. In planting, beginners should attend to one little matter: take out a trench across the bed, set the plants so near as to leave a couple of inches round them, pack them firmly with the soil, and then water thoroughly, and when that has drained away, cover the surface with the dry, unwatered soil. It is scarcely possible to have the surface too dry in winter if there is moisture enough below. In addition to this, I often cover the surface between the plants, when fairly growing, with a slight layer of dry road-drift and charcoal, which, besides helping to promote a dry atmosphere, slugs can wriggle along, but very slowly, amongst such material when dry. In addition, I may add, that *air* may be given freely when the external temperature is about 40°, especially when the sun has raised it higher; and *frost* must be excluded by covering the glass, and protecting the sides of the box or pit. *Pots* for the window, or greenhouse, may be managed in a similar manner; one large, or three small plants for a six-inch pot. This sort involves a little trouble; but that given, and these *little* matters looked to, there will be no disappointment. All the rest are easier managed, and will require less to be said about them.

2. PERPETUAL OR TREE VIOLET.—This is a useful variety. It well deserves the name *Perpetual*, as I have seen it bloom from September to June. The title *Tree*, may not be a misnomer, as this violet may suit that mode better than others; and I rather think it does: though each and

every one of them may be grown in that *moppish* manner where desirable. A number of complaints reached me last winter and spring that it would not bloom early. In every case that came under my inspection the parties had received a counterfeit—namely, the common double blue, a fine thing in its way, producing, when well grown, finer flowers than the *Perpetual*, or *Tree*, but then it will rarely or never bloom in winter—it may also be known by its flowers being flat and broad, whilst those of the *Perpetual* are orbicular. Unlike the *Neapolitan*, the common blue will not agree with the slightest forcing: the *Perpetual* never requires it. In pots, it will bloom splendidly in windows and greenhouses; it will also do admirably in a sheltered raised place out-of-doors, where it can have temporary protection in bad weather. Of course it would do better still in a frame or pit. The flowers are not, in general, very large, but they are produced very abundantly, and are very sweet. All Violets dislike stagnant moisture. Where other conveniences are wanting, they flourish at the foot of a wall, or fence, facing the south, south-east, and south-west, provided you have either a wide board, or a narrow straw-thatched hurdle, from fifteen to eighteen inches in depth, to place against them in wet and frosty weather. For *propagation* and *culture* in frames and pots, see *Neapolitan*—only, if bulk is desired, the first-formed runners may remain, as in a fine summer they will be sufficiently matured to bloom along with the mother or principal head. The soil should also have more loam in its composition. Mr. Tiley advertises a *Perpetual Tree white*: the common double white is a poor thing in winter. If this *Perpetual white* is at all equal to the blue in this respect, it will be invaluable where there are ladies. I have not yet tried it.

Forming Tree Violets.—This is best done by dividing plants two or three years old. A nice little head, with a fair supply of roots, and a clean stem between them a number of inches in length, are thus obtained. Whether these are planted out-of-doors, or potted, the stems must at first be supported by little sticks. The head soon takes an upright direction. Ere long, the stem increases in strength, and also in length little by little every year. When once potted, and valued for their singularity, care must be given to supply them with plenty of water, and an open airy place in summer, and to avoid all stagnant moisture in winter. Sour earth about the stems will make them *miffy* and short-lived. Even when not shifted every year into larger pots, the drainage should be examined, a little old soil picked away, and fresh surfacings applied; and round the base of the stem a little cone of bruised charcoal will be a safeguard. I had them thus grown of all varieties, one of the best was a *Neapolitan*; but I got tired of them: I saw little beauty in the bare stems, and, from a pot similar in size, I could get many more flowers from a plant grown in the usual way. Allowing the runners to festoon from the top for several generations, like an *Aaron's-beard* Saxifrage, seemed an improvement, where all was so *stilted*; but to carry out that idea in a moderate-sized pot pre-supposes considerable attention to rich surface-dressings and manure-waterings.

3. RUSSIAN VIOLET AND SUPERB VIOLET.—These are extremely useful single Violets; the latter larger than the common. They are easily propagated by seeds, runners, slips, and divisions, and should never stand long in one place, as young plants generally bloom most freely. They are seldom potted, but they are worthy a place in the cottage window, where they could stand outside in fine weather, and be brought inside in sleet and frost. They will bloom very freely, where sashes and other covering can be given them in winter. In common seasons, they thrive and bloom tolerably well on raised banks, by the side of fences, &c., where a few branches,

or other covering, may be given them in severe weather. From October and onwards, a few rows of them perfume a garden. I understand something grand in this way is looming in the *near*. A deep, loamy, well-drained soil is that in which all the varieties I have met with in this section delight. If the soil is light and sandy, and tolerably rich withal, the number and size of the leaves will keep the flowers in the shade.

4. THE DOUBLE BLUE AND DOUBLE WHITE.—The last is the most tender. Unless in very mild winters, neither of them flower much until spring. For fine effect, propagate and cultivate the same as the *Neapolitan*, by runners, slips, and divisions. As flowers are produced on the first-formed runners, as well as the crown, they may remain several years in the same ground, but the flowers are likely to get less and less in size. A rich, deep, dry loam is their delight. In such circumstances, the bloom from strong young plants is truly fine. In sandy and chalky soils the plants run too much to leaf. Need I mention again, that the blooms of all, when dried, long retain their scent. R. FISH.

CONIFERÆ.

(Continued from page 126).

JUNIPERUS COMMUNIS (The Common Juniper).—This species is a native of Britain, and the colder parts of Asia and North America, growing, under favourable circumstances, to the height of ten or twelve feet, forming then a thickly-branched and not inelegant low tree. Its perfect hardihood recommends it for all open and exposed situations, where few other plants would exist. There are several varieties, some of which far surpass the original species in beauty—namely, *Juniperus communis Canadensis* (The Canadian J.), a dwarf bush from three to five feet high; *Juniperus communis Cracovia*, found near Cracow, a handsome, upright-growing variety; *J. communis Hibernica*, and *Hibernica compressa*, the Irish Junipers; these are also upright-growing varieties; the latter, as its name imports, being very much compressed in its habit; *J. communis oblonga*, and *oblonga pendula*. The latter is a very elegant drooping variety. Both attain the height of ten feet, and are natives of China and Japan. And, lastly, *J. communis Suecica*, the Swedish Juniper, a well-known favourite variety. It is said that in the forest of Fontainebleau this variety has attained the height of fifty feet, and various articles of furniture are made of its timber. I mentioned this fine variety in my notice of Alton Towers; and as it is fifteen years since I saw them, and they were then eight feet high, I suppose they will be now nearly double that height. Why do not we plant this tree for timber, as its wood is so excellent for cabinet work? It is cheap enough—twenty-five shillings will buy a hundred of them a foot high at the wholesale nurseries.

J. DRUPACEA (The Drupe-fruited J.).—Native of the plains of Syria, where, in almost all sand, it thrives and attains the height of ten feet.

J. EXCELSA (The Tall J.).—This handsome species is a native of Siberia, the higher parts of the Himalayas, and North America. There it often rises to the height of forty feet, but the highest I have seen in this country was fifteen feet (see page 144). The timber of this species is excellent. There is a dwarf variety called *nana*, and in gardens *religiosa*, being used in some parts in sacrifices, on account of its aromatic qualities when burning.

J. FLACCIDA (The Weak J.).—This is a curious species, with a slender, elegant habit. Being a native of Mexico, it requires a greenhouse or conservatory to grow it in. The leaves are lance-shaped, and the branches are drooping; it grows to a great height.

J. FRAGRANS (The Sweet-smelling J.).—From Nepal; also rather tender. Very little is known of this rare species.

J. GOSSAINTHANEA.—This is a rare species. I saw several fine plants of it lately in Mr. G. Jackman's nursery, near Woking, in Surrey; and, from the habit and colour, I should say it will be, when better known and more full grown, a most elegant tree. It is perfectly hardy.

J. LYCIA (The Lycian J.).—A native of Greece, the Levant, and Siberia; a handsome species, growing fifteen feet high.

J. MACROCARPA (The Large-fruited J.).—I have seen some fine specimens of this silvery-leaved Juniper, and can confidently recommend it as a very ornamental species. The cones are of a pale blue when young. It is a native of Greece, where it is highly esteemed, and planted freely.

J. MEXICANA (The Mexican J.).—The branches of this Juniper are unlike all the rest; they spread out at the base, regularly shortening in upwards, and thus form a handsome pyramidal tree, some 40 feet high. Unfortunately it is too tender to bear the open air in winter in this country, but it is well worthy of a place in a lofty conservatory.

J. NANA (The Dwarf J.).—This small bush is found in Europe, Asia, and North America. It has more synonymes than perhaps any other species. It is the *J. alpina* of Ray; the *J. montana* of Aiton; the *J. communis nana* of Loudon; the *J. communis alpina* of Woblenberg; the *J. communis saxatile* of Pallas; and the *J. minor montana* of Bauhin. It is Willdenow that has named it simply *J. nana*, the name I have adopted; and a more expressive one need not be; it is truly a dwarf, seldom reaching, even when old, more than a foot high. It is useful to plant at a corner where two walks separate, or close to the walk of the Pinetum; arranging well with such plants as *Abies danbrassiliana*, *J. sabina prostrata*, and such-like alpine, low-growing Coniferæ.

J. OCCIDENTALIS (The Western J.).—This species, in its native wilds, is a giant among its kindred, rising to the altitude of eighty feet, forming a noble tree. It is found in great quantity on the higher part of Columbia, where it is greatly esteemed as a timber-tree. No doubt, when more plentiful, it will be grown extensively in this country, both for its beauty and usefulness.

J. OXYCEDRUS (The Thorny Cedar, or Brown-berried J.).—The species is confined to Europe. It is grown largely in Spain, Portugal, the south of France, and in Italy, and has been grown in Britain for more than a century. It is a very low tree, seldom exceeding twelve feet. There are three varieties, namely *taurica*, *echiniformis*, and *Witmanniana*. They are all handsome, and should be in every collection of any note; but in the northern parts of this country they are rather tender.

J. PHENICEA (The Phœnician J.).—Native, as its name imports, of the south of Europe. It is also found in Russia! and grows from fifteen to twenty feet high. A beautiful, light-green-leaved tree.

J. PSEUDO SABINI (The False Savin).—Native of the Altai mountains; growing much in the style of our common Savin, but more upright, and rather lighter green.

J. PYRAMIDALIS (The Pyramidal J.).—Not much is known of this species; there is a plant so named in the London Horticultural Society's garden at Chiswick.

J. RECURVA (The recurved Nepal J.).—A very distinct species, with both leaves and branches turned back, or recurved; the foliage is light green. It requires a dry soil, is perfectly hardy, and very ornamental in sheltered places. Exposed to the north winds it is apt to turn rusty in winter, much in the same style as the *Cryptomeria japonica*. The variety named *densa* is a

distinct one, and of more dwarf, compact habit. Both are very desirable.

J. SABINA (The Common or True Savin).—Grown in masses, this species has a fine effect. In favoured situations it will form almost a tree. Clothed with a rich brown bark, the dwarf variety, *prostrata*, is well adapted for rockwork, or to place on a lawn to form a sort of fringe to the shrubbery. The one with variegated foliage is pretty, and worthy of a place in a collection on that account.

T. APPLEBY.

(To be continued).

THE PETUNIA.

(Concluded from page 145.)

GENERAL MANAGEMENT OF PLANTS INTENDED FOR EXHIBITION.

It is well known to those cultivators who grow plants with an especial eye to show them for competition, that extra care and attention is required in order to beat their opponents, or, even if no opposition is offered, to win the approbation of the censors, and, consequently, a prize. Most societies give directions in their schedules to the judges not to give first-class prizes to inferior specimens, merely because they are the best exhibited, or, perhaps, the only ones present on the tables. This is quite right, and relieves the censors from a most unpleasant part of their adjudication. It is true, there are exhibitors selfish enough to argue, that as their productions are the best present they ought to have the prize offered for the best; but if such confessedly poor things were to have first prizes, the subscribers and visitors would be disgusted; there would be an end put to that spirit of emulation and desire to excel which ought to be the aim of all exhibitions to encourage and bring into play. Then again, such a law will prevent any competitors from bringing to the exhibition any fruits, plants, or vegetables, that are not, at least, respectable, and show that some extra care has been taken to bring those exhibited, at least, superior to the commonly-seen specimens in every garden.

These remarks will, I trust, be taken with candour, as I do not see how any one at all conversant with exhibiting matters can deny their truth; and I would advise every one showing garden productions never to exhibit any article but what is in good, fair condition. To do otherwise ought only to bring disgrace, and not honour or credit to the exhibitor.

THE PETUNIA is no exception, but must be well grown, and freely and finely bloomed, in order to be considered worthy of a prize. The way to manage so as to attain so desirable an end is my business, on this occasion, to describe. The time to exhibit them to perfection is about the last week in June (which is early) to the last week in July, which may be considered, in the generality of seasons, to be late.

Plants intended for this purpose should be well established the preceding autumn, and should not be allowed to flower till within a month of the time of exhibition. They may be kept in pots from three to four inches diameter through the winter. From the first moment of potting, up to the month of May, they should be frequently topped; that is, the two upper leaves, with the buds attached, should be carefully and neatly cut off with a sharp knife. Nipping off with the finger and thumb I cannot approve; it is, to say the least of it, a careless method, and crushes and mutilates a plant in the tenderest part, often causing many of the shoots to mould and perish in wet, damp weather; whereas, a clean cut with a keen-edged knife heals up quickly, and the plant is little worse by the operation.

As the plants grow they must be repotted as soon as

the roots reach the sides of the pots. They should never be allowed to become matted till placed in their blooming-pots. In March, it will be necessary to provide a number of short sticks; if they are painted a light green so much the better. At one of the spring pottings, before the roots have pushed into the new earth, thrust a circle of these sticks round the pot at some distance from the shoots; tie a short piece of nice small bass-mat to one of these sticks, so that the two ends of the mat are equal in length from the stick, then bring each end round a branch nearest to the stick, and, with the mat, draw it gently down to the stick, and tie it to it rather loosely. This is a nice operation, and requires a steady hand and attentive eye, or the shoot will break off from the main stem. When one branch is securely and safely tied, proceed to the next, and so on round the plant till every side-shoot is brought down, and the centre left thinly furnished. Cut off the ends of all the strong shoots, and the plants will soon begin to show they have had a careful hand at work to form them into bushy, round-headed specimens. This is the ground-work to commence with, and as the shoots advance in number and length must be repeated, and longer sticks made use of. If the shoots are too numerous, let them be judiciously thinned, so as not to allow them to crowd each other. The short sticks may be removed when the shoots do not require their directing support. As they advance towards blooming, they may require a few sticks in the centre of each plant to train each shoot into a position so as not to interfere with its neighbour.

The management as to potting, placing in a pit, smoking with tobacco to destroy the green fly, dusting with sulphur to destroy mildew, watering with liquid-manure, giving air, and other points of culture, I have already described under the head "Summer treatment." To these directions I have nothing to add now. If the cultivator has been successful in his operations, the plants for exhibition will, in May, be strong, bushy plants, eighteen inches high, and twelve inches through, and be showing plenty of flowers, which may then, if the show is in June, be allowed to come into bloom; but if in July, the buds must be taken off again, and not allowed to remain till the middle of June. All the energies of the plant must be reserved, in order to have a blaze of fresh, high-coloured blooms on the day they are required for the exhibition table.

T. APPLEBY.

INFLUENCES OF THE WET SEASON ON CROPS OF VARIOUS KINDS.

THE near approach of winter renders it necessary to take such precautionary measures as will protect the various products which hard weather is likely to injure. This is the more advisable, in consequence of the unusually wet autumn having rendered everything out-of-doors a perfect receptacle for water, the tissues or cells of plants being charged with water almost to the bursting point. It is easy, therefore, to perceive the effects that frost is likely to have on plants so gorged with superfluous moisture, which has scarcely ever been relieved by a dry day, nor yet (what is equally useful) a cold one. The atmosphere has been, in most cases, mild and warm for November, while the ground has been so repeatedly soaked with drenching rains, that, in spite of the absence of cold and frost, the autumn growth of many things has been much below the average of years. This is apparent to every one in the after-harvest-sown *Turnips*, many of which scarcely present anything more than the same mass of green leaves that they did two months ago, and that this tardy progress is owing to the cold, drenching rain is evident to every one; since the average atmospheric warmth, if fully equal to

former years, when the various members of the numerous *Cabbage family* continued their growth with more steadiness, if not with more vigour, than they sometimes do in the summer months. Now these perishingly cold rains have been more hurtful to the late-planted *Celery* than most crops, some of it will not arrive at the size and condition fit for blanching; while in former years, and under precisely the same treatment, the late-planted has carried on the supply in the spring, when the larger and earlier was no longer fit for use. This season it will only be fit for the commonest purposes to which green *Celery* is put. This state of things is the result of the long-continued wet weather we have had, in which the herbage has rarely ever been dry, and the ground soddened to the utmost with rain. Even grass, which is supposed to resist, nay, even benefit by the usual autumn rain, has, this season, made less growth since the end of September than is usual with it. Under such a state of things it cannot excite surprise if the more delicate portion of garden produce should have made but a tardy autumn growth. Young seedlings of the *Lettuce* or *Cauliflower* tribe, even where protected by glass, have scarcely been able to resist the decaying influence of such a protracted season, while a considerable portion have absolutely perished under it. The obvious tendency of so early and wet an autumn is to prolong the winter by lengthening its advent. In a usual way, we have more or less of moisture before severe cold sets in, and hardy plants are but seldom perfectly dry during November; but in the past season October has been substituted for that month, so that the horticultural autumn may be truly said to have "set in" a month sooner than usual.

It will be difficult to find a remedy for such a state of things, but many palliatives will suggest themselves. It will now be discovered to what good purposes efficient drainage may be applied; and if such do not already exist in our gardens, the present time must point out the necessity of making it so. The utility of tanks, channels, and all watercourses will also have been put to a severe test, and their purposes proved. Coupled with these is the quality of walks, roads, and paths, which a series of wet weather, if accompanied with traffic, soon finds out their defects. All these, and many more evils resulting from such drenching rains, have so far retarded the usual autumn work, that we must urge on our brethren to be on the alert when a change does take place; and all house-work being, as we expect, advanced as far as possible a-head of the season, and others, to which the inclemency of the weather offers but few impediments, must be pushed on as far as possible, in order that the general outdoor work may receive the united energies of the whole staff, when the period does arrive to bring it into action. A thoughtful business habit of contriving work will suggest many things which can as well be done in wet weather as in dry. We therefore advise our young friends to cultivate this useful part of their studies, as much may be gained by it.

Among the plants suffering from the absence of sunshine are the winter *Cucumber plants*, which, though in an atmosphere purely artificial, are not yet exempt from the causes which prove fatal to more robust productions out of doors; as, apart from the want of that all-important element of their existence, "sunshine," the atmosphere of hothouses is, or must be, more or less charged with that moisture which reigns everywhere. It may be true that a dry heat applied removes or drives off part of the water, but then it substitutes a temperature in its place ungenial to vegetation. That this is the cause of many disasters is too well known; nevertheless, there is no other way, and those who have young *Cucumber plants* struggling against the elements must act very carefully with them. Avoid, by all

means, "drip," and if the house or pit where they are growing be flat-roofed, or of low pitch, drip will invariably be the consequence. A homely, but useful protection to small plants is to suspend (from the roof) a large-sized bell glass over them; observe, this must be some height above the plant, so as to leave it in possession of the whole atmosphere of the house to breathe in, or a few large squares of clear glass placed in a steep slanting direction over them, and on their north sides is also useful, as it catches the drip from the roof on its outer surface; while its inner one, we expect, is too steep a pitch and too smooth to allow what moisture collects there to drip on the plants. Nevertheless, with all the care that can be taken, the progress at this untoward season is but tardy; still they may be carried through, and we advise our young friends to keep a vigilant look out for mildew in some of its forms. This is more especially necessary, as this plant cannot endure those forcible means made use of to eradicate it. From more robust subjects, the first approach of it must be instantly checked by rubbing over the spots with a soft brush dipped in lime-water, and a little quick-lime may be brought into the pit. The gas emitted by sulphur is too much for this plant. We need hardly observe, that all plants likely to introduce insects of any kinds must be kept carefully out of the way, as the means necessary to destroy these intruders is an ordeal too severe for this delicate subject, which, at this untoward season, requires more than the usual amount of nursing to ensure anything like a successful issue. Heat must be steady, and means taken so to balance its humidity as to be congenial; from 65° to 70° is about the proper temperature. But I will return to this subject at the first early opportunity.

J. ROBSON.

GREASING THE WHEEL.

By the Authoress of "My Flowers," &c.

It was a word of advice from the wisest of men, "Boast not thyself of to-morrow; for thou knowest not what a day may bring forth." Who among us lays this advice to heart? Who among us has holy boldness enough to say, as St. James directs us, "If the Lord will, we shall live, and do this and that?" Who among us but looks forward, and expects, at least, not only length of days, but continuance of all the blessings we possess? We may not boast, perhaps, but we *presume*. We do not consider what a day may bring forth; we do not think about it; we have had good health, *good luck*, no accidents; and we forget whose hands fashioned us, and from whom we receive and hold the breath of life. Whichever of my readers can feel a humble, blessed consciousness, that such is not *their* case, happy and highly favoured is their state! Many there are, many more may there be, of that blessed band! They alone dwell in peace; they alone are watching and ready, when the hour of trial comes. Those who think little or nothing of the uncertainties of this world are careless and daring in their conduct. One would think that a man who rests upon *good luck*, or upon the fact of never having met with danger and accident, or who never troubles his head at all about how or why he is alive and well, would, at any rate, take common care of himself, and not run foolish risks to put himself in the way of mischief. But this is seldom the case; and such fool-hardiness is seen among men as makes us almost suppose they are without reason, as well as without God in the world.

A few weeks ago, an instance of this fool-hardiness took place in a neighbouring parish; and I hope it may be a warning to some of my careless readers to avoid such dangerous acts; for in one little moment an affliction may be brought on that will cause us distress and suffering for the rest of life.

A farmer was engaged in thrashing out corn with a thrashing-machine. It was a singular circumstance, that one morning, one of the men employed on the farm went to his master,

and said, "Sir, I had a very strange dream last night. I dreamed that one of us had our hand smashed in the 'chine." Of course no notice was taken of this, except, perhaps, a smile; but the man himself thought a good deal about it, and kept as much at a distance from the machine as he possibly could. In the course of the day the wheel wanted greasing, and the farmer's head-man, or bailiff, prepared to do it. The horses were going on; and on being spoken to of the danger, the bailiff said, "Oh, I can't spare the time; I can do it while they go on; I can't waste time while I'm greasing the wheel." So on went the horses, and the bailiff crept between them to the axle of the machine, where the grease was to be applied. The man was very careful of his hand as he put the grease in; but while thinking of the one, he totally forgot the other. His left hand was thoughtlessly placed on a part of the machine, which caught it, and crushed it in an instant! Bleeding, and in agonies, the poor man was taken up, as soon as the horses could be stopped, and carried to bed. The surgeon was summoned, and gave it as his decided opinion that the hand must be taken off and part of the arm also. The poor fellow was so distressed at the idea of losing a hand, which supplied him with bread, that he begged for further advice, which was cheerfully granted; and he chose the surgeon whose opinion he should like to have. He came; but alas! there was no hope; the hand must be taken off just below the elbow; nothing else could possibly save his life. The operation accordingly took place; and the man, who rose up in the morning in health and strength, and began his daily work with all his usual vigour and light-heartedness, when evening closed in lay on the bed of suffering, deprived of a limb, and disabled for ever from gaining his bread in the way in which alone he was fitted to do it. One moment's heedless folly has brought the bitter repentance of a whole life. The five or six minutes, which could not be spared to take a wise and rational precaution, have caused days and weeks of suffering, of loss of time, and of heavy self-reproach—hardest of all to bear. What must be the thoughts of a poor man, lying helpless and crippled for life, when he thinks that his own mad stupidity has laid him there? When he thinks that he needed not to have done so foolishly—that the very boy who was driving the horses must have known his danger, and would not have done the same? Oh, how he must mourn and lament, and *wish* he had not been a fool, when it is too late; when his poor crushed hand is off and buried, and nothing can be done but to bear the loss, and pray for grace to profit by the lesson, and that the trial may be sanctified to him!

I hope and trust that this poor man's accident may be a warning to those of my readers who are headstrong and daring. Every day of our lives we see instances of thoughtless, reckless risk; and, perhaps, few of us have not been guilty of some one or more ourselves. It is not weak or wicked to be cautious: it is so, when we persist in doing a dangerous thing which need not be done. It was not duty that obliged this poor fellow to grease the wheel while the horses were going on; nor is it duty that leads us often into mischief. We are very well aware that we are ready enough to get away from duty when it leads us into perilous places; we can often find a good excuse for escaping *then*—for being prudent and cautious *then*. It is our own self-will and hot-headedness that runs away with us, and gives us reason to repent, often to the end of our lives.

I must say a word more upon this occurrence, before I address a startling question to my readers. The dream—it was a striking and remarkable one. Such things have been before. We know that under the Old Testament dispensation God appeared unto men in dreams, and many wonderful events were revealed in visions during sleep. But those days have passed away; and we have no Scriptural warrant for expecting revelations by means of dreams. Still, the Lord works in whatever way He pleases; and without ignorantly and blindly attending to our dreams, as many do, we would not totally set them aside, or laugh contemptuously at them; for what the Lord has used as an instrument to work His will should be no matter of scorn to us. In this case, the fact occurred, and I do not ever remember to have heard of so striking a coincidence before.

And now, one question before I close my paper. How are we greasing *our* wheels? We are all pressing forwards to *something*; but are we greasing our wheels for time, or for eternity! If we cannot spare time from our earthly business to seek "the kingdom of God and his righteousness,"—to take "oil in the vessels with our lamps,"—we shall lose that which is worth more than a right hand—we shall "*lose our own souls*." We shall find ourselves caught and entangled in a snare that will crush us to all eternity, from which there is no deliverance and no hope. We shall look back from the bottomless pit with weeping and wailing and gnashing of teeth, upon the senseless folly, the raving madness, that chose "the pleasures of sin for a season," instead of the lasting glories at "the right hand of God."

Readers! we are all of us thrashing; thrashing for time, or for eternity; and One speaks to us in plainer words than those of a dream, "Repent, for the kingdom of heaven is at hand." Let the poor bailiff, on his sick-bed, teach us a mighty truth. We may be "in the morning like grass that groweth up;" in the evening "we may be cut down and withered." Let each of us ask our own heart this great and startling question—How are we greasing *our* wheels?

A FEW OF THE BEST DAPHNES.

In order to give an account of these, I must include the *Daphne odora* and its varieties, for these are beautiful, and deserve for winter nosegays a place wherever room can be spared for them. They are excellent to plant out in large conservatories, where they are just at home, although almost hardy enough to stand out under a warm wall or corner, with a little protection during severe weather in winter. They do well, also, wintered in a pit or frame, where the plants are not too large for such places.

This species generally begins flowering in January, and continues more or less in flower until May. No plant is more desirable for nosegays; it is so very sweet, and continues so long in perfect beauty after being cut for this purpose. I have no doubt it would be rooted very well from cuttings by those who have proper places for this work, but they are more commonly grafted upon the common spurge laurel, *D. laureola*. Several years ago, when I first saw the variety, *D. odora rubra*, I was so much struck with it, that of course I wanted it in some way or other, and my friend who possessed it said, I have young plants of the *D. laureola* in pots, and I will put you on one graft; he did so; he took off a scion with two crowns or a forked top, and inserted it into the pot by the side the stock it was to be worked upon, and inarched it to the stock just below the fork, and placed it in one of his heated pits, where it soon united; and the plant came to my hands with its forked top, and standing upon two legs as it were. It so stands now, and a fine specimen it is, too, but the stock on which the scion was inarched is but a very little larger now than when the scion was put on, whilst the scion is nearly three times the size of the stock at the present time. I am not inferring from this circumstance that many of the *Daphnes* might not be raised from cuttings, for I have known the *D. pontica*, and others, to be raised from cuttings, thirty years ago, under a north wall, under hand-glasses.

There is another variety called *D. odora variegata*; but I consider *D. odora rubra* the best.

The *Hardy Kinds* are as follows:—*Daphne hybrida*, or, as it is most generally known by the name of *D. dauphinii*, Dauphin's *Daphne*. This is one of the most desirable plants that any garden, great or small, can possess. It is a beautiful plant to grow against a south wall or warm corner. It does well as a shrub in the open border, and from the goodness of the plant, it is worth a place, planted out in a conservatory, where it would be seen in bloom nearly the whole year, more or less.

We have a large plant of this upon a conservative wall covering a space of about five feet by five to six feet. It is not nailed in like a Peach-tree, but just fastened up, sufficient to secure it firmly to the wall, with a fine thicket of breastwood over the face of the whole tree, protruding about from six to nine inches from the wall. It seldom requires any pruning more than it gets by being so much cut for nosegays, as its flowers are very sweet-scented. Nearly

every shoot over the whole tree terminates in a bunch of bloom of a purplish-red colour, and the whole foliage is of a dark shining-green colour. It commences flowering in September, and continues in bloom, more or less, until the end of April. Ours is a perfect gem at this moment (Nov. 20th). I was, with a friend, a few evenings since admiring the beauty of this plant, and to see the moths flying from flower to flower (mostly of the *Phalena gamma*, or the Greek G. moth-kind) proved that they admired its sweetness too.

This shrub was planted out here the spring following the severe winter of 1837-8, and has never been protected. I believe it is nearly as hardy as the *D. laureola*, on which it is grafted. When the weather is very severe, it causes some of the blossoms to fall off; yet, after a change again to a south-westerly wind and a few showers, the tree looks as gay as ever.

Daphne cneorum.—This is well named "the Garland flower," and a prettier little hardy plant does not exist. It should always be a front border plant when planted out, and have as nice, open, sunny spot as can be given it. It is often grafted, like others, upon the *D. laureola*, and small plants of it look very pretty in this way, either in pot or planted out. It may be planted out in almost any good garden soil when grafted on the *laureola*, but when the plant stands upon its own roots it should be planted out in peat, in a dry, warm, sunny situation, which makes the finest specimens to stand the test of years. I do not know how many legs of *D. laureola* it would require to bear up a specimen we have of this beautiful plant on its own roots, and many rooted plants might be taken from it if required, for the outer stems, as they come in contact with the earth, put out roots readily, consequently it is increased easily by layers. There are two varieties of this plant, namely *Variogata* and *Grandiflora*. Both the species and its varieties are equally beautiful. It commences flowering in April, and continues oftentimes more or less during the summer months, of a beautiful reddish-pink colour, and very sweet-scented. The flowers keep perfect a long time after being cut for nosegays, for which it is so very desirable.

Daphne pontica is a very desirable kind as a front shrub in the plantation, or as a bunch or group by itself. Low ground, or a cool situation, suits it best. Indeed, it does very well under the drip of other trees, and also best upon its own roots in such places. It grows too straggling and rampant to be grafted upon the *D. laureola*—though grafted plants are all very well for a few years' growth of any of the kinds. The stems of this species, as they come in contact with the earth, put out roots freely enough, so that, of course, it is readily increased by layers. The whole plant is of a pale-green colour, rising from two to three feet in height. Its flowers are numerous, and of a yellowish-green colour, and very sweet scented. It flowers in April and May.

Daphne Mezereum, commonly called Mezereon, has two varieties, the white and dark red. Though a native of our own woods it is none the worse for that. These are plants of very pretty growth, suitable as front plants to the plantation, and, as a poet says,

"Though leafless, well attired, and thick beset
With blushing wreaths investing every spray."

These plants are increased by seed, and require a good sandy loam. The ripe berries look very tempting upon the plants, but they are poisonous. The Mezereon is one of the first shrubs to be seen in bloom in the plantation. February and March is its time of flowering, and, if not the only shrub then in bloom, it will for certain be the most showy and the sweetest.

Daphne Collina, *Neapolitana*, and *Gnidium*, and several others are grafted upon the *D. laureola*, and, as shrubs, are very well where the number of kinds is the consideration.

The *Daphne laureola* is itself a particularly useful plant to live, flourish, and flower under the drip of trees, and in the shade where few other things will live.—T. WEAVER.

CROSS BREEDING OF FOWLS, AND CURE FOR THE ROUP.

I HAVE read attentively nearly all papers that have appeared in THE COTTAGE GARDENER relative to that now

"fashionable subject, the Cochin-China fowl and its rival the Spanish;" and throughout the whole I find each advocating the cause of his favourite bird too frequently by vague assertion or "mere fancy." The table by "Gallus" is not at all satisfactory; it would require that the same number of fowls of each kind and sex be kept together for a considerable length of time—say twelve months—the food they consume weighed, and the return they give in eggs also weighed; we could then come to something like a correct estimate of the relative value of the different kinds. But at present one asserts "the Spanish lay larger eggs, and are more profitable to keep in consequence of consuming much less food;" another affirms "that Cochins do not eat more than Spanish or Dorking," and that "their frequent and pertinacious desire to sit is their only drawback."

The Cochins, on all hands, are allowed to be very productive, but their very great desire to hatch is a failing in the breed. The Spanish, on the other hand, are seldom or never inclined to sit, and lay eggs of a much larger size. Now, it appears to me that a cross between the Spanish and Cochin would be the very perfection of fowls; and a breed of fowls may be raised between them combining the good qualifications of both, just as you, Mr. Editor, would take the pollen from one flower, and put it in another. Take an instance: If I had a fine *formed* flower of a colour which I was desirous of altering in its progeny, what would I do? I would look about me for the best-formed flower of the colour I wished, and impregnate with this pollen my favourite-formed flower, and the probability would be that I should obtain some of the desired colour, and equal in form to its female parent; and, reasoning from the world of flowers to the world of animal life, I would find the same general law to hold good in both. "But, ah!" says the amateur, "I'll have no mongrel race; I'll have nothing but pure breed." Now, I do believe this to be a great mistake. How, I would ask, have we improved our breed of cattle? Is it not by breeding with those animals who have what we want in greatest perfection, and by following it out that we find them in the improved state they are now in; and I cannot see why the breeding of poultry should be an exception.

I have been led to make these remarks in consequence of having last year a chicken from a cross between a Poland hen and a Cochin-China cock. It turned out a hen, and began laying in the beginning of January last (being only hatched in July), and laid, on an average, five and six eggs a-week until the end of March following, when she manifested a desire to sit, and was then set on a dozen Cochin eggs, eleven of which were hatched by her; and *before the chickens were three weeks old* she had begun laying again, and has continued doing so, I may say, almost without intermission ever since; for when she showed an inclination to hatch again, a single day, or two, at the most (very different from Cochins), in a crib, put the fever off, and in eight or ten days she was laying again. She moulted about a month ago, and was scarcely finished moulting when she began again to lay; and although she may not lay so many days running as Cochins, still I have no doubt she lays within the year a greater number, and the eggs are considerably larger. I have two pullets this year from the same hen and a Cochin cock, which seem to promise equally well; and in the spring of next year I mean to try a cross between a Spanish cock and a Cochin hen, and I have no doubt that the progeny will be larger and stronger than the Spanish; and the number of eggs will be increased from the productiveness of the Cochin, and "the pertinacious desire to set" will be lessened by the Spanish, and altogether a better fowl will be produced for profitable purposes (and that is what is really wanted) than what either will produce separately, and all my observations on the breeding of fowls confirms it.

I have kept fowls for several years, but have never known what disease was, until this season. A disease (I am at a loss to give it a name) has seized on nearly all my young broods when about half or three-parts grown, and several of them have died in consequence—wasting and pining away. The trouble, to all outward appearance, being in the head. The first thing that strikes one is the ruffled state of their feathers, afterwards a discharge from the nostrils, and as the disease advances, the head, between the eyes and the

bill, swell up in small pimples nearly the size of a small pea, and very frequently a kind of froth is seen working about over the eyes. After being from home for two or three days, I found one with the disease in a very advanced stage, and on taking it up in my hand it appeared little heavier than the bones and feathers should have been. I took the little sufferer and washed all its head about the nostrils with soap and milk-warm water, and dried it with a cloth, gave it a little toasted bread steeped in tea, part of which I had to put down its throat, being so blind it could hardly see. Having before tried everything recommended in book, and many things beside, without effect, I again tried as a change (thinking it very probable the bird would die at any rate) some iodide of potassium. I dissolved ten grains in an ounce of water, and having taken a small piece of loaf-bread an inch square, and half that in thickness, I dropped some of the iodide on the bread, say about sixty drops, and gave it. Next morning I again washed it with soap and water, and dried it, gave it a few grains of corn, which it either could not see to eat, or did not feel inclined to do so. I then gave it a little toast steeped in tea, as before, and concluded with giving it the same quantity, as before, of iodide, and in the evening I repeated exactly the same, toast and iodide. The following day it was decidedly better, and ate the little corn I gave it evidently with a relish, after which I gave it the toast and iodide, and continued that treatment for about a week, when I put it out with the other fowls, and only occasionally afterwards giving it a little of the same medicine; in about a fortnight to three weeks it was as well as any fowl in my walk. Since then, I have treated many of them in the same way, for the same disease, and since having done so, I have not lost a single fowl, and I shall be glad if it be found to be as useful to others as it has been to me. I have found cream-of-tartar the best laxitive medicine for fowls, and have almost always ended my cure by giving them a little; as much as will lie on a sixpence, for a full-grown fowl, is a sufficient dose.

If you think the above remarks of use to any of your numerous readers they are at your disposal, and you may hear again how my other cross-breeds succeed.—A. S. W., Glasgow.

EATABLE FUNGI.

(Continued from page 110.)

THE *Hydniums* form another genus, most of which are eatable, and several highly esteemed as food. *Hydnum erinaceum*, which is found growing upon old oaks, forms a common article of diet in the Vosges, a range of mountains separating Lorraine from Alsace. *Hydnum coralloides* is eaten in Piedmont and Tuscany. *H. auriscalpium*, which is indigenous to this country, and found growing on fir canes; and *H. leoninum*, a native of Sweden, are also eatable. *H. album*, has somewhat the flavour of the Cantarille. *H. repandum*, however, is the one most generally esteemed, and is reckoned amongst the most delicate fungi of Italy. In preparing it for the table, being a very dry fungus, it requires to be cooked for a long time, or it is tough; but when well stewed in rich gravy, it forms an excellent dish, and has a slight flavour of oysters.

The *Boletuses* form another genus, which, although including poisonous species, contains also many that are valued as an article of diet, as much, if not more, than any previously mentioned. So highly, Dr. Badham says, is the *B. edulis* esteemed, that gold, and silver, and dresses, may be trusted to a messenger, but not this *Boletus*, because he would eat it on the road! Perhaps no genus of the fungi supplies such abundance of food to so large a proportion of the population of the globe. The species are generally of large dimensions, and are found in immense profusion. *B. edulis* is the easiest cultivated of all fungi, and is found growing naturally almost in every locality where an oak-tree or trees exist, and *B. scaber* is almost as abundant. According to Drummond, many species of *Boletus* are used as food in Western Australia; and I have no doubt that those fungi seen by travellers, the dimensions of which equalled crouching lions, belonged to this genus. The *B. scaber* is a favourite amongst the Russians and Poles, who have many ways of cooking it.

In Hungary, a soup is made of *B. edulis*, and considered a great delicacy. In other parts of the Continent, many species, as *B. subtomentosus*, *B. granulatus*, *B. edulis*, *B. scaber*, &c., are brought into the markets, but, undoubtedly, *B. edulis* is considered by all as the best, and in my opinion, when fresh, is good eaten in any way. I have eaten it raw with bread and butter and enjoyed it. My experience, however, has taught me that it is best to remove the tubes of this genus before using them as an article of diet, as independent of their being watery, they have a hot peppery taste, and are very liable to be loaded with insects or their eggs.

With respect to dressing the *Boletuses*, more especially *edulis*, I quite agree with Dr. Badham, when he says it will improve any dish. I will give, however, the following recipes:—

Boletus edulis soup, as made in Hungary (Paulet). Having dried some *Boletuses* in an oven, soak them in tepid water, thickening with toasted bread, till the whole be of the consistence of a purée, then rub through a sieve, throw in some stewed *Boletuses*, boil together, and serve with the usual condiments.

Boletus edulis is also fine fried in fresh butter, served up on dry toast, and eaten with or without beef-steaks, the seasoning with salt, pepper, &c., left to the cook.

Agarics form the largest genus of the fungi, and produce many, both poisonous and eatable. I regret that space will not allow me to enumerate all its species, which, as is well known, have from time to time been used in different parts of the globe as food. The British I shall briefly notice here, as my next paper will be confined to the British fungi exclusively. The *Agarics* are dispersed in almost every region of the globe, affording to both savage and civilised natives an abundant supply of wholesome and nutritious food. On the Continent, and more especially in Poland and Russia, several *Agarics* are used and highly esteemed as an article of diet. *Agaricus translucens* has been reported to be eaten by the people of Montpellier, but it is a very watery mushroom, and must form a very indifferent food. *A. nivalis* is said to be eaten by the Tuscans, but I cannot recommend it as an article of diet in this country.

A. vaginatus is eaten largely by the poor of Muscovy, but cases are on record in which it has proved poisonous. *A. procerus*, which is known by many other names, is largely used throughout France and Italy. The receipts for dressing *Agarics* are numerous. I shall, therefore, only give a few which may be also found most useful for dressing fungi generally.

Fried Fungi.—The usual method of frying fungi is either in oil or fresh butter. The latter I consider far preferable, and served up in the following way:—When the fungi are nearly done, have ready some dry toast, place it in the frying-pan, and in a few minutes turn it, place the fungi on the toast, sprinkle them with a little pepper and salt, and when the toast is warm through, convey them to the table, and eat while hot.

Grilled Fungi.—Many fungi are far preferable grilled, but will require a little butter to prevent their burning, and may be seasoned as in the last, with pepper and salt; as, however, the essence of the fungus is often deposited in the fire in a liquid state, my experience has taught me, if the cook possesses good patience, and time is not an object, that toasting on a fork, or in a Dutch-oven, with many fungi, is far preferable, as in this way they do not get burnt, and the liquid is preserved.

Stuffed Mushrooms.—Take large mushrooms, full-grown, but remove the gills, and place in lieu of them the following stuffing:—Bacon shredded, crumbs of bread, chopped herbs, and a little garlic or eschalot (as for omelettes), salt, pepper, and a taste of spice. Broil in paper as a maintenance cutlet, moistening with butter when necessary.

Mushroom Dumplings.—An agreeable dish may be made from the common mushroom, by simply cutting up the small (or button) mushrooms, and forming them into a dumpling, with pieces of bacon the size of a dice, and a sprinkle of salt and pepper.

F. YORKE BROCCAS.

(To be continued.)

SHANGHAE OR CHINA FOWLS.

THIS fine sort of fowl has been often described, but I consider that amateurs have been rather too limited in their descriptions, and that their rules for the fancy birds of this breed are too narrow and restricted; so that many families of fine and pure-bred Shanghae fowls cannot be brought to submit to them; a short explanation of which I will endeavour to give.

First, then, "The beak should be short." Now, I do not notice that it is shorter in these than other fowls; but I think the front part of the head is longer.

Next, "The comb should be medium-sized, single, and straight," but I often see it bent from side to side, and occasionally slightly inclined to be double at the upper extremity, and often it is over the medium, and as I do not know of any other breed of fowls having this peculiar bent comb, so I see no reason why it should be objected to.

Then, "They should not be tufted." But were not some tufted, there would not have been any necessity for this rule, and it is very constant in some families. Some persons think these fowls descended from the great St. Jago fowl, which is described as often tufted, in which case I do not consider it right that the tufts should be objected to. Others seem to fancy they were obtained by the Chinese from some of the South Pacific Islands. Could any one throw light on this subject it would be interesting. They are described as having "double gills or wattles," but this I consider a mistake, as all I have seen have rather short, broad, single gills; the ear plates are, however, large, folded, and somewhat pendant, which may have given rise to the error. These are all points of the head, and I believe a fowl may differ in them, and still be a pure-bred bird; not that I should consider all of the imported fowls to be of the true stock. Again, I think fanciers have dwelt too much on colour, the dark birds being least prized; but I think them generally the heaviest fowls; and the buffs they endeavour to breed without black, not because it is the natural colour, but because it is difficult to be obtained; for the same reason the white are esteemed, though I think they will often be found to be somewhat the smallest. In the other points I heartily concur, and I think the most important consideration is weight; next shape, wide shoulders, full well-covered thighs, resembling a Dutchman's breeches; short, thick legs, and feather-footed. Long, lank, and narrow-made birds will occasionally be produced, but I should not keep them for stock. Others, which are admired by some, have no feathers on their feet, but I think the feather-footed birds approach nearest to the original type.

The tail is the best criterion by which to judge of the purity of the breed that I know of—this is always small, and though composed of the same number of feathers as those of other fowls, they are very short, scarcely reaching above the bunch of curled rump feathers, and the chickens attain to a large size before any tail makes its appearance, though the pullets sometimes get tails earlier, and a half-bred chick will sometimes be a long time before it has a tail.

A five-toed fowl I should look on with suspicion, although it might be perfect in all other respects. The productiveness of the Shanghae fowls is very great, the hens being good layers, close sitters, and laying again soon after hatching; the chickens seem hardy, and grow fast, though they feather slowly. The eggs, the shells of which are often dark-coloured, are good eating, and the young fowls are excellent for the table, being fine-flavoured and juicy. To this I can bear testimony, for having reared many more than I want for stock, and not having been able to part with them, I have killed several, and always found them delicious, much better in flavour than any fowl I have ever eaten, and though never cooped or fattened, they were in the highest condition.

The way to raise large fowls is to hatch them early, feed them well, and not to breed from relations. The gait of the male bird is peculiar, rather crouching, resembling that of a cock turkey.

They are a quiet fowl, not straying far from home, are easily kept within bounds, and seem to bear confinement well. I do not know why they should be called Cochinchina fowls, as they are brought from the more northern part of China, principally from the town of Shanghai and its neighbourhood.—B. P. BRENT, *Bessel's Green, near Seven Oaks.*

NORMANDY.

(Continued from page 112.)

THROUGHOUT France generally, and especially in the Departments of Calvados and La Manche, female accomplishments assume quite new and unexpected forms. Near Bayeux, I saw a woman on her knees by the roadside breaking stones; another, near Periers, was mowing some clover in a field, to take home to her quadruped, probably a horse, who was too tired to carry it himself; and in the town of Periers, I noticed a female postman—a *facteuse*, instead of a *facteur*—going her rounds to deliver the letters and newspapers. She had the usual tin box slung before her, but had dispensed with the glazed hat and the livery coat. At Sartilly, a lady was painting the wheels of a cart, while her husband was employed about finishing the body; and between Sartilly and Avranches, many women were to be seen lustily at work with the flail, threshing away with right good will and thorough good humour. One party, consisting of half-a-dozen threshers, was composed of five women and one man; and, as the diligence passed, they laughed, as if our appearance amused them quite as much as their's did us. It may be expected, that if women thresh, they also winnow; and female hands were flirting fans of a different description to those usually seen in ball-rooms, for they tossed and shook no trifling measure of wheat.

The harvest here is variously reported. The *Journal d'Avranches* for September 5, quoting the *Moniteur*, states, that "certain journals have published estimates as to the harvest of 1852, which would tend to make it supposed to be insufficient. These journals have been wrongly informed. The result of the information received by government is, that the harvest of 1852 will be, on the average, equivalent to that of ordinary years, and even superior, by nearly one-fourth, in certain departments, which furnish a great proportion of the cereals consumed in France." But the *Conseil d'Arrondissement* of Avranches, in reply to the questions put in the letter of *M. le Préfet*, dated August 12, 1852, is of opinion

1st. That the harvest of 1852 is inferior to the harvest of an ordinary year, for wheat and rye.

2ndly. That the amount of deficiency is about one-fifth for those two species of cereals.

3rdly. That the produce would be sufficient for the wants of the arrondissement if the harvest of barley and of buckwheat is not compromised; with this observation, that the barley is already injured.

4thly. That the influence of the temperature must be considered as the cause of the diminution and the inferiority of the produce.

5thly. That the atmospheric accidents have been the unusual cold in spring, the heavy and continual rains in May and June, and the excessive heats which succeeded during the month of July; that all these accidents were necessarily injurious, in the first place, to the blossoming, and afterwards to the formation and the development of the grain, whose yield will, consequently, be lighter.

Meanwhile, the French press is calling general attention to the subject. It fears, if not a scarcity of bread by the middle or end of the winter, at least a *dearness* of that article; and it is especially apprehensive of the consequences of such a fear acting upon the popular mind. When we remember the past history of France, the amount of a harvest becomes a matter of vital importance to the country.

Before taking leave of the *Conseil d'Avranches*, I will mention, that "In consideration of the lateness of the cereal harvest this year, of buckwheat particularly, it expresses the wish that the opening of the sporting season may not be fixed before the 20th of September. It petitions *M. le Préfet* to take this expressed wish into consideration."

Englishmen would not like a similar interference, and would be jealous of trusting any single individual, whether *Préfet*, or Lord-Lieutenant of the county, with the power of shifting the 1st of September, and of sparing the partridges till the end of the month. But there can be no doubt that it would be a good thing if some constitutional authority—for instance, the county magistrates assembled in quarter sessions—could exercise a like discretion. In France, the *ouverture de la chasse*, or opening of the shooting-season, takes

place at a different date, in different *arrondissements* and *communes*, according to circumstances. Liberty, in the abstract, is a very good thing; but, if we are to have any legislation on the subject of game, the liberty of killing half-grown birds, and of wading amidst standing, or outlying crops, is a great piece of folly.

Fishing is also locally regulated. An *Ordonnance* published not long since, sets forth, that the taking of fresh-water fish is forbidden in all navigable and floatable rivers and streams, in all canals, brooks, and water-courses whatever throughout the Department of the Seine-Inférieure, at all hours of the day and night, during the time of spawning, under certain penalties. The spawning season is fixed from the 1st of January to the 31st of March inclusive, for trout; from the 1st of March to the 1st of May, for eels; from the 1st of April to the 31st of May, for barbel, bream, chub, pike, roach, perch, carp, gudgeon, and bleak. The taking of sea-fish which ascend the rivers and streams, such as salmon, sturgeon, lamprey, flounder, and mullet, may be practised at all seasons, attending to the regulated size of the flounders and mullets taken; but the fishers must throw back into the river any fresh-water-fish which they may catch along with the sea-fish during the close time. Smelts may be taken only from the 1st of October to the 15th of April. Fishing may be practised an hour before sunrise, and an hour after sunset. It is prohibited during the rest of the night, except at the arches of bridges, at dykes, locks, and sluices, where it may go on by night as well as by day. The fishing for salmon, flounders, mullets, &c., is also excepted from this prohibition, for they may be taken at any hour of the day and night. The shrimp and prawn fishery (by nets) is also restricted, for the sake of sparing the fry of turbot, cod, soles, &c., which are usually taken with them. But, it should be remembered, that a single fish of prey—and all are fishes of prey—a middle-sized cod, or skate, or turbot, will make more havoc among the rising generation of their own nearest relations, than half-a-dozen human shrimp-catchers.

Normandy cider has so well-established a reputation as to be deservedly world-famous. But the Normandy of the old *régime* has, since the First Revolution, been divided into the five departments of Seine, Inferieure, Eure, Calvados, Orne, and Manche. Though cider is abundant in all these, Calvados is pre-eminent, both for quantity and quality, and is the main source of that enormous supply of terrestrial nectar which annually flows from the earth, through the stems of innumerable apple-trees, to assuage the thirst and cheer the hearts of hundreds of thousands of hard-working mortals. The beverage itself derives a name from the department, exactly as Moselle, Champagne, and St. Julien are wines that are designated by the title of their place of growth and vintage. CALVADOS, printed in large letters on the sign-board or shutters of any house of entertainment in Normandy, means to say that *there* a draught of Calvados cider is to be had.

A distinction is made in Normandy, which is hardly known out of it, between the different qualities of cider. The strongest and the best only is honoured with the name of *cidre*; the weaker and inferior—anything in the shape of a second-chop brewing—is styled *boisson*, or drink. Of both immense quantities are consumed, of the latter especially, which, when well-flavoured, as it most frequently is, and from a cool cellar, is even more deliciously refreshing, on a hot summer's day, than the more potent liquor. *Cidre* only is thought worthy of being bottled; *boisson* never, except in large stone ware receptacles for the day's convenience and consumption. *Boisson* is always very cheap; it flows everywhere, almost like water. Cider varies in price, according to its real or fancied merit, and the pains and taste bestowed on the mode of bottling it. The *dearest* I have ever tasted was at an inn at Montevilliers, where this special *bin* was called *Sillery de Normandie*, and leaded down at the cork, and smartly labelled, like Champagne. We were charged a franc, or tenpence, the bottle; and it certainly was excellent. But we are now using some very nearly as good, at six sous, or threepence, for a large stone bottle holding four good tumbler glasses. The most luxurious of these drinks is first-rate *draught* cider out of one of their large *barriques*, or barrels, that is just fresh tapped.

A sentence or two from a Havre paper will illustrate both the great drought of April 1852, and the plentifulness of cider in Normandy:—"The want of water in those localities where there are wells and reservoirs only, and no streams, has come to such a state, that in some houses they make use of *boisson* for domestic purposes. There are many parishes where it is absolutely necessary to fetch water eight *kilometres* (about four miles English), and where, consequently, there is real economy in employing *boisson* to take its place. We are assured that many (religious) processions have already been undertaken, in order to obtain the cessation of this so injurious drought."

Immediately after entering within the boundary of Normandy, the abundance of this popular beverage is perceptible, from the manner in which it is, in Norfolk phrase, *slumped* upon the table at every meal, at every inn. Large wide-mouthed decanters full of the pale yellow fluid, slightly bubbling and sparkling from the cask, and without stoppers, which are never dreamt of, drop hither and thither on the well-covered board, and utterly push the water-bottles aside. It is an effectual, though not altogether a complete expulsion of the weaker by the stronger. Empty the decanter of *boisson*, which stands at your elbow, and, *presto!* behold another filled to the very neck; but you sometimes have to ask two or three times for a glass of water fresh from the well. At a *table d'hôte* breakfast, all the cider you can swallow is included in the charge; I have sometimes thought, that the more you drink of it, the better they like you; but if you take coffee at your morning meal, *that* is considered an extravagance, and is made an extra item in the bill. For the almost universal fashion at the Norman inns, is to eat only two meals a day, and those right good ones, breakfast at ten, and dinner at five o'clock. I have long tried to find the difference between the *dejeuner*, and the dinner, but cannot discover it. At first, a false clue to the secret was given by the occasional absence of soup; but we went further, and fared *better*. A genuine Norman breakfast begins with soup, with oysters, and prawns, perhaps, as a preliminary skirmish to the coming onslaught; then it proceeds legitimately through boiled beef, salad, ragout, cutlets, fish, roast meat, and so on, and concludes with a dignified dessert of fruit, cheese, and sugar biscuits. Everybody drinks *boisson*, cider, and wine; water *may* be had with a little pains-taking. Tea and coffee are no more alluded to than if the company were at one of Lucullus's suppers in the hall of Apollo. It is absurd to apply the terms of "breakfasting and dining," to such a course of regimen. A real Norman never "breakfasts," at least in public; he only eats two dinners a day. And there is little distinction of sex in this matter. If a lady sits down to table, and eats a plate of soup, a slice of beef, a mutton chop, a couple of rolls, a quantity of salad or green haricots, a slice of gruyère, a pear, and a peach, with a tumbler or two of Bourdeaux wine slightly diluted with water,—Will any Englishman call that a "breakfast," at whatever hour of the day the deed may be done? And if the same feats are performed at any subsequent hour, what is that? Dining again. But every country has its own customs; and it must be allowed that the appearance of the Normans generally does full credit to the liberality of their diet. Many of the women are perfect models of the Michael Angelo style of figure; and men six feet high and upwards, bony and muscular, with broad shoulders, large good-humoured features, and the limbs of giants, which do not quite answer to our usual notion of Frenchmen, any ten of whom can be thrashed by any one Englishman. I got considerable credit for observing that the Normans could not be an ordinary people; otherwise they would not have effected the conquest of England; and, on reflection, I cannot confess the remark to be either false or too flattering. At Valogues, particularly, I was struck with several faces which bore a remarkable resemblance to the portraits of the notables of our early history. Fancy might be something, but not everything in the matter. D.

(To be continued.)

DORCHESTER POULTRY SHOW.

THIS Show, on the 24th of November, taken altogether, was a very good one for the first; there were 200 pens of birds, including several pens of extra stock. "The Town

Hall was much too confined a place, and the coops much too small for Cochins; and some of the wire fronts had much too small a mesh, some not big enough to put your finger through; but next year no doubt they will improve. Neither was the arrangement of the pens well managed—some being very low, and others up too high. The judges were Mr. Baily, of London, and Henry Hinxman, Esq., of Durnford, near Salisbury.

The *Spanish* were very indifferent; *Dorkings* good; *Cochins* very good, especially Mr. Steggall's and Mr. Devenish's. The first prize Cochins were the best match ever seen, both in size and colour. They were small, but good-shaped, and looked older than specified. The *Malays* were middling; but some very nice specimens of *Game* fowls were there; and the *Spangled Hamburg*, very few entries, were fair. *Polands*, only two competitors, were very nice, but all had dark feathers, more or less, in their breasts. There were some very beautiful *Bantams*, especially those which gained the first prize, belonging to A. C. Sayers, Esq. *Geese*, good. *Ducks*, a large entry, and some very fine specimens, both Rouen and Aylesbury white. *Turkeys*, very few and middling. Considering the weather, the attendance was very good, and a great many sales took place. Parties were very eager to buy; and to those who are not initiated in the £1000 prohibitory clause, as at Birmingham, could not understand the enormous difference in price of birds of nearly the same apparent value. The attendance before two o'clock, price 2s., was very good; and after that, at 1s., there was quite a crowd, and it was very difficult to get about.

SPANISH.

Cock and two hens.—No first prize. 2nd. Mr. C. Clark, Street.
Cockerel and three pullets.—No award.

DORKING.

Cock and two hens.—1st. Mr. E. Pope, Great Toller. 2nd. Mr. W. Pope, Symondsburly. 3rd. Mr. F. Noyes, Laverstock.
Cockerel and three pullets.—1st. and 2nd. Mr. E. Pope. 3rd. Mr. W. Pope.

SHANGHAE.

Cock and two hens.—1st. Mr. C. D. Saunders, Tarrant Hinton. 2nd. Mr. F. C. Steggall, Weymouth. 3rd. Mr. A. C. Sayers, Ramridge, near Andover.
Cockerel and three pullets.—1st. Mr. W. Symonds, Milborne. 2nd. Mr. J. Crane, jun., Tolpuddle. 3rd. Mr. H. Fookes, Whitechurch.

MALAY.

Cock and two hens.—1st. Mr. C. Clark, Street. 2nd. Mr. H. Williams, Stinsford. 3rd. Mr. A. C. Sayers, Ramridge.
Cockerel and three pullets.—No first prize. 2nd. Mr. W. Manfield, Dorchester.

GAME.

Cock and two hens.—1st. Mr. J. T. Ensor, Dorchester. 2nd and 3rd. Mr. J. Crane, jun., Tolpuddle.
Cockerel and three pullets.—1st. Mr. J. T. Ensor, Dorchester. 2nd. Mr. J. Crane, jun., Tolpuddle.

GOLDEN-SPANGLED HAMBURGH.
(No award).

SILVER-SPANGLED HAMBURGH.

Cock and two hens.—No 1st prize. 2nd. Mr. C. Clark, Street.
Cockerel and three pullets.—1st. Mr. C. Clark.

GOLDEN-PENCILLED HAMBURGH.

Cock and two hens.—1st. Mr. C. Clark, Street.
Cockerel and three pullets.—1st. Mr. C. Clark.

SILVER-PENCILLED HAMBURGH.

Cock and two hens.—No 1st or 2nd. 3rd. Mr. R. Fookes, Milton Abbas.

POLAND.

Cock and two hens.—1st and 2nd. Mr. T. P. Edwards, Lyndhurst Railway Station.
Cockerel and three pullets.—1st. Mr. T. P. Edwards.

BANTAMS.—GOLD OR SILVER LACED.

Cock and two hens.—1st. Mr. J. Goodenough, Godmanstone. 2nd. Mr. J. Crane, jun., Tolpuddle.

BANTAMS.—BLACK, WHITE, &c.

Cock and two hens.—1st. Mr. A. C. Sayers, Ramridge. 2nd. Mr. R. Fookes, Milton Abbas.

GEESE.

Gander and one Goose.—1st. Mr. W. H. Drummond, Troytown. 2nd. Mr. W. Manfield, Dorchester.

DUCKS.

Drake and two Ducks.—1st Prize to Mr. R. Genge, Waterson; Mr. E. Pope, Great Toller; and Mr. T. D. Chard, Tarrant Hinton. 2nd. Mr. W. H. Dunman, Troytown. 3rd. Mr. T. P. Edwards, Lyndhurst Railway Station.

TURKEYS.

Cock and one Hen.—1st and 2nd. Mr. W. H. Manfield, Dorchester.

HITCHIN POULTRY SHOW.

The *Hitchin and Home Counties* first exhibition of domestic poultry took place on the 20th, 22nd, and 23rd instant;

and a first attempt has seldom achieved better success than crowned the efforts of the spirited projectors. Mr. Goodwin, and the gentlemen of the committee, were aided in the arrangement of the details by one of our spirited Birmingham amateurs, and all were, and had reason to be, gratified by the result.

As usual on these occasions, the Shanghaes formed the chief attraction, and numbered nearly one-third of the fowls exhibited; nor did they fail to do their part toward the support of this popularity, for in half-a-bucketful of eggs which were removed from the pens during the exhibition, for the purpose of being destroyed, there were five only which were not laid by Shanghae hens.

Mr. Taylor, of Shepherd's Bush, showed a pen of his pretty *Andalusian fowls*, whose compact, domestic look, and bright slate-coloured plumage, form a decided improvement, in appearance at any rate, on their first cousins, the Spanish, of funereal hue.

JUDGES.—Edward Hewitt, Esq., Eden Cottage, Spark Brook, Birmingham; and Mr. Baily, Mount Street, Grosvenor Square, London.

COCHIN-CHINA. (WHITE.)

Cock and two hens.—1st. John Fairlie, Esq., Cheveley Park, Newmarket. 2nd. Mr. William Lort, Ward End, Birmingham. 3rd. Mr. G. C. Peters, Moseley, Birmingham.

Cock and three pullets.—1st. Mr. G. C. Peters, Moseley, Birmingham. 2nd. Mr. William Lort, Ward End, Birmingham.

COCHIN-CHINA. (COLOURED.)

Cock and two hens.—1st. Mr. H. Gilbert, 17, Upper Philimore Place, Kensington. 2nd. John Fairlie, Esq., Cheveley Park, Newmarket. 3rd. C. Punchard, Esq., Blunt's Hall, Haverhill.

Cock and three pullets.—1st prizes to Mr. H. Gilbert, 17, Upper Philimore Place, Kensington; Mr. G. C. Peters, Moseley, Birmingham; Mr. W. Lort, Ward End, Birmingham; and Mr. R. Steward, South Town, Yarmouth. 2nd. W. T. Squire, Esq., Barton Place, Mildenhall. 3rd. C. Punchard, Esq., Blunt's Hall, Haverhill, Suffolk.

DORKING. (WHITE.)

Cock and two hens.—2nd. Mr. J. Jennens, Moseley, Birmingham.
Cock and three pullets.—1st. Mr. H. Forster, Markyate-street, Herts. 2nd. Miss Mary Lane, Maidencroft, Hitchin.

DORKING. (COLOURED.)

Cock and two hens.—1st. Mr. Oliver Steed, Baldock. 2nd prizes to Mr. F. Thursby, Abingdon, Northamptonshire; Mr. H. Forster, Markyate-street, Herts; and Mr. G. C. Adkins, Edgbaston. 3rd. Mr. Joseph Lucas, Hitchin.

Cock and three pullets.—1st. Mr. T. Nice, Great Bradley Hall, Suffolk. 2nd. Rev. J. Boys, Biddenden, Kent. 3rd. Mr. W. Harrison, Bagworth Park, Leicestershire.

SPANISH.

Cock and two hens.—1st. Hon. Mrs. Astley, Swanton House, Thetford. 2nd. Mr. John Taylor, jun., Cressey House, Shepherd's Bush, London. 3rd. Mr. James Barber, Great Yarmouth.

Cock and three pullets.—Prizes withheld.

GAME FOWLS. (WHITE.)

Cock and two hens.—1st. H. Thurnall, Esq., Royston, Hertfordshire. 2nd. Mrs. Hoggett, Norton, near Baldock.

Cock and three pullets.—1st. Mr. W. Groom, Holt, Norfolk.

GAME. (COLOURED.)

Cock and two hens.—1st. Henry Thurnall, Esq., Royston. 2nd. Mr. W. Groom, Holt, Norfolk. Two 3rd prizes. Henry Thurnall, Esq., Royston.

GAME. (COLOURED.)

Cock and three pullets, chickens of 1852.—Two 1st prizes. Henry Thurnall, Esq., Royston. 2nd. Mr. A. Cannell, Cringleford, Norfolk.

GOLDEN-PENCILLED HAMBURGH.

Cock and two hens.—2nd. Mr. T. Church, Acle, Norfolk.
Cock and three pullets.—1st. Mr. T. Barber, Acle, Norfolk.

GOLDEN-SPANGLED HAMBURGH.

Cock and two hens.—1st. Mr. G. C. Adkins, Edgbaston, Birmingham. 3rd. Mr. T. Cane, Baldock.
Cock and three pullets.—No entry.

SILVER-PENCILLED HAMBURGH.

Cock and two hens.—1st. The Hon. Mrs. Astley, Swanton House, Thetford. 2nd. Mr. J. Dutton, Bury St. Edmunds.

Cock and three pullets.—1st prizes to Mr. Charles Thurnall, Whittlesford, near Cambridge; and Francis L'Estrange Astley, Esq., Burgh Hall, Thetford. 2nd. Rev. Justice Chapman, Clareborough Vicarage, East Retford. 3rd. Mr. James Monsey, St. Miles, Thorne Lane, Norwich.

SILVER-SPANGLED HAMBURGH.

Cock and two hens.—1st. Mr. Joseph Jennens, Moseley, Birmingham. 3rd. W. J. Vivian, Esq., Singleton, Glamorganshire.
Cock and three pullets.—No entry.

MALAY.

Cock and two hens.—3rd prizes to Mr. M. Ridgway, Dewsbury, Yorkshire; and Mr. W. Harrison, Bagworth Park, Leicestershire. Class not Meritorious.

Cock and three pullets.—Prizes withheld.

POLAND FOWL. (GOLDEN.)

Cock and two hens.—1st. W. J. Vivian, Esq., Singleton, Glamorganshire. 2nd. Mr. C. Stephenson, 2, Loudoun Place, Brixton, Surrey.
Cock and three pullets.—2nd. Mr. C. Stephenson, 2, Loudoun Place, Brixton, Surrey.

POLAND FOWL. (SILVER.)

Cock and two hens.—1st. W. J. Vivian, Esq., Singleton, Glamorgan-shire.

Cock and three pullets.—2nd. Mr. C. Stephenson, 2 Loudoun-place, Brixton, Surrey. 3rd. Mr. Youell, Yarmouth.

POLAND FOWL. (OF ANY OTHER COLOUR OR VARIETY.)

Cock and two hens.—1st. Mr. G. C. Adkins, Edgbaston, Birmingham.

2nd. W. J. Vivian, Esq., Singleton, Glamorgan-shire.

Cock and three pullets.—No entry.

MIXED BREED.

3rd. Mr. Hainworth, Hitchen, and Mr. Bennell, Hitchen.

(The Judges disapprove of this class.)

FOWLS. (DISTINCT VARIETY, NOT NAMED IN THE ABOVE CLASSES.)

1st. Mr. John Taylor, jun., Cressey House, Shepherd's Bush, London.

2nd. Mr. E. Hughes, Yarmouth. 3rd. W. J. Vivian, Esq., Singleton, Glamorgan-shire.

BANTAMS. (GOLD LACED.)

Cock and two hens.—1st. Mrs. Elizabeth Roper, Croxton, Thetford, Norfolk. 2nd. Mr. U. Spary, Markyate-street, Herts.

BANTAMS. (SILVER.)

Cock and two hens.—1st. Mr. H. J. Jones, Bedford. 2nd. John Fairlie, Esq., Chevely Park, Newmarket.

BANTAMS. (WHITE.)

Cock and two hens.—1st. Mr. M. Leno, jun., Hemel Hempstead.

BANTAMS. (ANY OTHER COLOUR OR VARIETY.)

Cock and two hens.—1st. Mr. James Monsey, St. Miles, Thorne Lane, Norwich. 2nd. Mr. Wheeler, Hexton House, Herts. 3rd. Mr. M. Ridgway, Dewsbury, Yorkshire.

GUINEA FOWL.

Cock and two hens.—Mr. Joseph Whiting, Hitchin.

TURKEYS.

Cock and two hens.—1st. John Fairlie, Esq., Chevely Park, Newmarket.

2nd. Mr. W. Harrison, Bagworth Park, Leicestershire; Mr. A. Cannel, Cringleford, Norfolk; and Mr. G. Roberts, Kingswalden, Herts.

3rd. Mr. Charles Thurnall, Whittlesford, near Cambridge; and Mr. John Steed, Baldock.

GEESE.

Gander and two geese.—1st. Mr. J. Taylor, jun., Cressey House, Shepherd's Bush, London.

DUCKS. (WHITE AYLESBURY.)

Drake and two ducks.—1st. Mr. Arch, Clifton, Beds. 2nd. Mr. C. Thurnall, Whittlesford, near Cambridge. 3rd. Mr. Robert Tingey, Henlow Beds.

DUCKS. (COLOURED VARIETIES.)

Drake and two ducks.—1st. Mr. Youell, Yarmouth. 2nd. C. Punchard, Esq., Blunt's Hall, Haverhill, Suffolk.

MUSCOVY.

Drake and two ducks.—1st. Mr. John Steed, Baldock, Herts.

PIGEONS.—Twelve prizes were awarded to Mr. G. C. Adkins, Edgbaston, Birmingham; and Mr. Beazor, Yarmouth; Mr. O. Steed, Baldock; and Mr. J. Playford, Yarmouth, had each a prize.

TO CORRESPONDENTS.

BEE-KEEPING.—“The three questions asked me by your correspondent, B. B., at page 210, I will answer in this communication. First, I must ask B. B. to remember that the word ‘enormous’ was not applied by me to swarms, but to one swarm; and B. B. must also understand that both that term, as well as the expression ‘amazing quantity,’ &c., were only incidentally used in acquainting you, at your request, with my experience of the ‘Country Curate’s’ system, and not with a view to publication. Before alluding to the subject of B. B.’s questions, I have to inform you that five hives were tried by me on that plan, though I said nothing of the fifth in my last to you, and for this reason;—It was my intention greatly to alter this hive (though not destroy it), which would, of course, prevent it being a fair subject for experiment. When I did alter it I found it very full of bees, and containing nineteen pounds of honey—in fact, full; but the plan of the hive (a wood and glass toy affair) is miserable, as you may well imagine when that is all it will contain. Three of the four others I consider the best I have in all respects, but regret now to report badly of the remaining one. This failure was a swarm of June 24th, and an earlier one than one of the last three alluded to. The hive that threw off two swarms in one swarmed June 20th, and is as strong as any I have, weighing now 21 lbs. contents, and full of very savage bees, which I like. On looking over my apiary on Wednesday last, for a good hive, to give a friend in exchange for a Cochinchina cock, I pitched on the failure, weighed it, found it contained at least 21 lbs. of honey, and thought all ‘ouleur de rose.’ My gardener (a great hand at bees) remarked, ‘They seem very quiet, Sir;’ and so they might, for on turning it up there appeared a very very few in it. To-day I smoked it down with *Racodium cellare*, and it did contain a queen, though her majesty was small and poor looking; and the bees, about 3 lb., filled a dinner tumbler of the ordinary size. I have just most carefully weighed the honey, and find it 22½ lbs.; so my Wednesday’s calculation was 1½ lbs. under. Of these five hives the wood and glass toy hive was not shut up at all; the rest only until the evening of their swarming days. Three were moved to new stands, one hundred yards from the old place; and two to new stands, forty yards from the old place. The failure (?) was moved one hundred yards, so was that which threw off the two swarms in one; the good old hive forty yards. While I was a month at Scarborough, my heaviest straw hive went wrong, and was of course emptied by the other bees; and whether the uproar injured the ‘failure,’ which stood next it, you must judge—that is the opinion of my gardener. Question 1.—I use three-sized hives of straw; one weighs, empty, 3 lbs., another 7 lbs., the third 9 lbs. All three have straw tops, with 3¼-inch holes in them. The first has a perfectly flat top, and measures (inside measure) 12½ in. by 9½ in. The second is

shaped like the old bell-hive, but a portion of the top flat, and measures 14½ in. by 10 in. deep. The third, which I alluded to as “a very large hive,” measures 14½ in. by 13½ in. deep. The shape of this last is, I know, against all rule; but they do very well with us. Question 2nd.—I never did weigh a swarm, though I have seen and hived a great many, and know a large one, when I see it, even on a hot day. Question 3rd.—I broke up, August 1st, three hives, each weighing (contents of course—honey and comb) as follows:—First, 36 lbs.; second, 32 lbs.; third, 30 lbs. Same day I broke up two old hives of wood, to convert into Taylor’s—first, 34 lbs.; second, 27 lbs. You will be interested in knowing that the bees driven out of two of the first three mentioned were joined and put into an empty hive, and sent the same day to the moors, with the cap in its top full of honey, which the good old hive made, to start them with. This hive returned containing 18 lbs. of moor honey, and the cap as full as it went. At the same time I sent to the moors two late swarms; one returned containing 33 lbs., the other 35 lbs. The above is the ‘amazing quantity,’ with the addition of 22½ lbs. got from the failure (?) an hour ago. My plan of dealing with Taylor’s hives is exactly similar to Investigator’s plan of dealing with Golding’s; and our success seems pretty much the same, except that, perhaps, his top would not hold more than 28 lbs., whereas mine hold about 33 lbs. full. We all here think that if I had had twelve Taylor’s, instead of three, this season, every top would have been full. 12 times 33=396, supposing each hive, of course, to be reasonably strong to start with. If I live to another season my plan will be, seven ‘Taylor’s,’ five ‘Country Curate’s.’ ‘Investigator’ says July (all July) was very productive; so I found it. I cannot account for the wonderful quantity of honey gathered so late this last season; I never before found it so. We had no rain during the month of July in the day-time, and fearful heat, but splendid showers at night. Pray excuse the length of this, and believe me yours truly. P. S. October 27.—This should have been posted a fortnight ago. My bee-keeping, I admit, is neither for pecuniary profit nor scientific enquiry. I am tempted to add, that if they shut up their old hives for such long periods, it is not to be wondered at that when they are let out, and fly back to their old stands, they are not recognised, if scent has anything to do with it.—C. R. R.”

CYCLAMEN LEAVES ROTTING-OFF (Flora).—This has probably received rather too much wet, out-of-doors, but do not despair; take away every leaf carefully, that shows the least trace of decay. Put the plant in any window where you can give it air in this mild weather. Do not give much water until the weather changes, or the plant seems to want it, by the first symptoms of drooping; prevent frost from hurting it; top-dress with a little rich, light soil; strew some powdered charcoal over the top of the tuber, whence you remove the fading leaves, and unless there is something radically wrong, such as having been shaded when the leaves were growing, we think you will yet be rewarded with bloom.

GLOXINIA (P.).—You ask how to shade in a light forcing-house, glass all round. We do not think shading will be required now. When the sun gets strong it will. Any usual mode will do. We generally place them in the front of such a house, and paint the glass a little higher than their tops, with hot, double size, and we find this effectually saves the bloom.

VIOLA ARBOREA (Subscribers).—See an article to-day by Mr. Fish.

CLIMBERS (An Old Subscriber).—In addition to those you have for stove, *Passiflora princeps*, *Passiflora kermesina*, *Allamanda cathartica*, *Hoya carnosa*. We presume there is plenty of light. For the middle house, *Mandevilla suaveolens*, *Kennedyia Marryattæ*, *Tacsonia pinnatifida*, *Tecoma jasminoides*, or *Cherere*; for greenhouse, *Dolichos lignosus*, *Jasminum gracile*, *Hardenbergia macrophylla*. Lists of climbers for different purposes have been given lately.

FLOWER-GARDEN (Turquoise).—Your planting is perfect, on the principle of contrasts; we cannot alter a leaf, unless it were 15 (*Unique Geranium*) to *Saponaria calabrica*, for this reason, that young plants of *Unique* do not flower freely, and that old ones will make the bed too high for 16 and 17, without constant attendance to pegging and training. Again, 15 is your match for 20, and it will get higher than 20; if you change 15 for 20, perhaps it will suit better than in *Saponaria*. Then, 20, 21, and 22, would be higher than their opposites, 15, 16, and 17, and that is, no doubt, what you intended. You are certainly not “A Novice.” There is not one out of ten, of old practicals, who could do it half so well. The shapes of 10, 11, 12, and 13, are very unusual, but we shall engrave the whole some day or other.

INDIAN SEEDS (W. C.).—One-hundred-and-forty-five Indian seeds, correctly named, 120 of them are the very pick of the Indian Flora, and the rest not at all so common as we often see from India, and great judgment exercised in the selection, but without a particle of practical knowledge of what we want, and what we can manage in England. We question if there is a nurseryman, or botanic gardener in the three kingdoms, who would give the value of the paper in which they are packed, for all the seeds. If you imagine a line drawn across our Indian territories, from Bombay to Sylhet, you may lay it down as an axiom, that there are not ten kinds of seeds on the south side of that line that are worth the carriage from India; and not twenty seeds from the first fifty or sixty miles to the north of that line.

NOISSETTE LAMARQUE (Some One).—You did wrong by treating this Rose like a Banksian Rose, and so kept it from flowering in the autumn; you cut in the small wood, and cut out the strong shoots. Do exactly the contrary, and you will be rewarded with autumn flowers; but if it comes too strong after the first flowering, you had better give a slight root-pruning, say early in June.

BULBS AND BEDS (An Old Subscriber).—In the first place, are you willing to lay out £20 or £25 on bulbs for your seventeen beds, if that would plant them, which we much doubt? Be content with about 500 mixed *Hyacinths*, 600 mixed *Early Tulips*, 1000 mixed *Narcissus*, 5000 mixed *Crocus*, 100 double *Tulips*, 500 *Spanish Iris*, 500 *English Iris*, in mixtures, 600 or 700 double, single, and star-flowered *Anemones*, about 300 *Turban Ranunculus* in three colours, 50 *Fritillarias*, 100 *Crown Imperials* in four colours, 50 *Martagon Lilies* in four colours, 500 *Colchicum autumnalis*, 50 *Dogtooth Violets* in two colours, 50 *Feathered Hyacinths*, 50 *Grape Hyacinths*, 50 *Musk Hyacinths*, 1000 *Winter Aco-*

nites, 1000 double and single *Snowdrops*, with as many florist's bulbs as your own fancy tells you. We would not plant a quarter of your space with bulbs. Your garden will look more like a nursery in Holland than anything else; too much of a good thing is as bad as too little, and yet the above will only make a scanty clothing for your space.

GLADIOLI (Regular Subscriber).—The heights are relative, but what the proportions are on your soil we cannot say. The highest is 1, *Gandavensis*, orange-scarlet; 2, *Ramosus*, white and red; the rest are about the same height, or, say on an average, a yard high, and the colour various shades of red and orange. *Psittacinus*, *Gandavensis*, and *Floribundus*, may be planted any time between this and April. The right name of *Floribundus* is *Oppositiflorus*; and if you have it true, it is all but white. The rest of them should be planted now. The time of flowering will be governed by your locality, and the time of planting; for instance, if you plant *Psittacinus* now, it will come in flower next June; plant again in the beginning of February to bloom in July; plant in March for August bloom, and in April for September and October bloom.

TROPEOLUM TUBEROSUM.—Wareham says—"I dug up my *Tropæolum tuberosum* a day or two ago, the result was—Twenty-one tubers, larger than the original, for which I gave 1s.; twenty-two about the same size; twenty-four somewhat smaller; and something like sixty very small. I cooked a few, and they were very nice, resembling Asparagus somewhat in flavour. The small I have pickled. They are not amiss raw, as a salad. A paper in *Chambers' Edinburgh Journal* mentions that they produce fifteen to eighteen tubers; if that is the average, I must consider mine as a good crop; and I think I should have had more had I earthed it up, as there were many immature tubers outside the ground. It was manured with wood ashes and burnt sticks, half-charred. Though it cannot be expected to supply the place of the Potato, yet I see no reason why it should not be cultivated as an esculent. The tubers keep well, and, as an occasional dish, would, I think, be found useful. Can you suggest a way to make it flower well?" Your crop was very good, a little above the average on good land. Tastes differ so much in these things, that we do not like to say much either way. We have tasted them, and all the Oxalises that have been recommended, and we still prefer the worst potato to the best of them.

ROSES (Ibid).—They will do perfectly well where you say, and they require little or no sun in winter; same with Pinks and Carnations.

NAME OF HARDY SHRUB (C. G.).—Yours is the Sea-Buckthorn, or Sallowthorn (*Hippophae rhamnoides*); one of those few bushes that will grow well in sea-sand, to the edge of the tide.

FUCHSIA-BED (M. Fermanagh).—Your compost is very good for a Fuchsia-bed; indeed, too good to be passed—One-part garden mould; one-part turf, ashes, and a little sand; and two-parts turf. Fuchsias will grow well like willows in such a soil. Make it full two feet deep for them. But do not think of planting climbers in the centre of such a beautiful bed; nor a *Corymbiflora Fuchsia* either, which, instead of being "too delicate," is so ravenous, that it would eat up all the others before the end of the season. For a row in the centre, *Riccartonii* or *Gracilis* are the cheapest, and as good as any if you transplant them every other spring, so that they do not encroach on the new sorts all round. Look at the list we gave last July, before you decide on what kinds to plant. Your *Cleopatra Fuchsia* will grow too strong for *Dr. Jephson*, so you must keep them well apart, with others between.

BEES IN TAYLOR'S HIVE (A Subscriber).—Our correspondent says:—"I have a stock of bees in Taylor's Boxes, as described in his 'Bee-keeper's Manual,' third edition, page 17. The stock-box they have been in three years, the combs are getting very black, so that I should be very glad to change them into another, and I think there is now a chance of so doing, if I knew how to proceed; they being very strong the summer before last, I put a cap on, *fast*, so that I cannot now take it off. I have been following the side-box system, as described in the above work, page 29, but have not succeeded very well, as they swarm most seasons, and scarcely ever fill the side-box; last summer they threw off a strong swarm in June, and were very full afterwards. I put a side-box too, they worked very well into it, but did not above half fill it, and by what I could see through the glass, I thought there was little or no honey in it, so I thought I would let it remain till the bees left it, and were in the stock-hive, and then take it away, and put the stock-hive in its place. I have tried several times, but always found a great many bees in it, so I thought I would let it remain till the weather became cold. Last night being very cold, the thermometer out down to thirty-two, with cold wind, and the Staffordshire hills covered with snow, but as soon as I stirred the box they were all on the move, as usual. I tilted the box up two inches on one side, hoping they would go into the other at six o'clock; I then let it remain till ten o'clock, but then found them all, as usual, in the side-box, and very irascible; in fact, one flew out and stung me, whilst lowering the box down on to the floor-board. This morning I find them there as usual, and on examining the stock-box, found but three or four bees in it, but very heavy indeed with honey, full quite three-parts down. I have put it in its place again, but should be very glad if I could take it away, so that the bees may have the box with new combs; but how will they succeed, the box being but half-full of combs? There is plenty of honey in the stock-box, and I should be glad to know how to give it to them in the best way. I always feed at the top, with tins, as described in the above work, page 65. Would it be better to put the honey in the comb in the tins, and feed them in that way; and would they increase the combs at this season of the year? or would it be better to put the box the bees are in, on the top of the stock-box, and let them help themselves? but I fear in that way they would again take possession of the stock-box, with the old combs, which I do not want them to do." You may safely take the stock-box away, but cut seven or eight pounds of honey-comb out of it, and place it under a cap or bell-glass, upon the top of the box the bees are in, and when they have emptied the combs of honey, give them another supply.

SHANGHAE OR COCHIN-CHINA FOWLS (Brixton).—These are one and the same, and we have abided by our determination to call them *Shanghae* only. We cannot make our correspondents always do so. The variety is not known in Cochin, and they are found only about Shanghae, and other northern districts of China. "China fowls," as you suggest, would be a correct name, but we think *Shanghae* is accepted generally.

The following, from a correspondent in Gloucestershire, quite agrees with what we have ascertained from a traveller recently from China, and which we shall soon publish in another form. "You would oblige by informing me, if you can, why the 'Poultry World,' in speaking of China fowls, use indiscriminately, as they do, or, in fact, why they use at all, the prefix 'Cochin,' and do not call them simply 'China fowls?' I have endeavoured, but in vain, to ascertain the origin of the name 'Cochin-China,' as applied to fowls, and cannot learn that there is, but, on the contrary, I believe, from all I have learned, there is not, any breed peculiar to and to be found in that particular part of China, or bearing its name. I have kept China fowls for nearly four years, and possess birds bred from the largest sort, and some of the earliest (if not the first, except the Queen's, presented to Her Majesty by the Emperor of China) introduced into England; those birds, however, came from a far more northerly province, viz., that of Peang-nan, in China Proper, to which place, also, I know that the best birds in this country, that is, those that have taken prizes during the past and current year, are indebted in part, if not wholly, for their parentage. The synonyme of *Shanghae*, which has now become generally current, was given to the race to which mine belong merely because they were shipped from the Port of that name, and as a distinction from the smaller class of birds which at the earliest English Exhibitions were described and acknowledged by the Judges as *Cochin-Chinas*, between which and mine there is a great difference, as there is also between those originally and those now received as *Cochins*. In one of your recent numbers, an article appeared stating as a necessary characteristic of pure *Cochin-China* fowls that they must have no tail feathers, I should be glad to know upon what authority it is so stated. I maintain that pure bred China birds (cocks), of the finest sorts, come from what part of that country they may, have, or ought to have, perfect tail feathers, but of a dwarfish description; they should, I am told, be fourteen in number; and if any of these are wanting, the attention of the judges at exhibitions should be directed to ascertain whether such feathers have been lost accidentally or plucked intentionally to meet the erroneous and absurd fashion of the day, which appears to be 'that the best China fowls must be a buff colour and tail-less.'—T. A." We do not remember anywhere its being stated in these pages that *Shanghae* fowls should be without tails altogether, but we are quite sure that cocks of the pure breed have no sickle feathers in their tails.

POTATO-ONION (F. Withers).—Plant offsets in early spring, about the beginning of March, in rows eight inches apart, and the point of each offset just above the surface. The soil as for other onions. They have completed their growth by September, and may then be taken up to plant again at the end of October, or to be kept until the following spring. Do not earth them up, nor give any cultivation except an occasional earth-stirring.

PARLOUR AQUARIUM.—Clericus would be glad to know where he can purchase one of these. He also requires some seed of *Polygonum vacciniifolium*.

EXCHANGE OF DUCKS, &c. (Vicar).—We have given notice that we cannot insert such notices in future. We are not merely liable to advertisement duty, but give offence to advertisers.

WHEAT DIBBLING MACHINE.—J. R. N. wishes to know which is the best for making the holes and delivering the seed at the same time.

BEES (H. Edwards).—Leave the comb in the hive, tie a covering over the mouth, hang it in a dry place, and put a swarm into it next year.

DISEASED GRAPES (A Subscriber, Guernsey).—The berries of your Muscats were affected with what is technically called "the spot." The following is extracted from *The Cottage Gardeners' Dictionary*:—"It is a gangrene, probably occasioned by an irregularity in the supply of moisture and vicissitudes of temperature, but especially if one of the extremes is much below the degree of heat most favourable to the healthy growth of the plant. Muscats are particularly liable to this disease." Muscats require a higher temperature than most other grapes, and that of your greenhouse was probably much too low during our recent ungenial weather. The large *Haricot Bean* you enclosed, and which you state is commonly cultivated in the south of France, would be advantageously grown by our cottagers if hardy enough for our climate; its green pods and dried seeds being equally excellent for boiling. It is probably the *Lima* variety, and if so, requires the plants to be forwarded in a hotbed.

WORM-CASTS ON LAWN (Henricus).—These cannot be entirely prevented. Frequent waterings with lime water keep the worms from coming near the surface.

SHANGHAE COCKEREL (A new Subscriber).—Send your address, and state what aged bird you require. The other information you seek will appear in due time.

PUMICE STONE (Pteris, Dublin).—This will do very well for a small fernery.

TROPEOLUM TRICOLORUM (G. P. Willand).—We cannot give you the name of your plant by the two small leaves sent. The *Tropæolum tricolorum* that has put up four inches, and now died down again, we should say has been kept too wet, and most likely its roots have decayed too; whether or not, stop watering until you see if it will put out again, which probably it will not do for several months. September is about the time this plant begins to shoot out, at which time it should be potted. Until growth reappears the pot and tuber may be placed upon a dry shelf.

NAMES OF PLANTS (Troublesome).—The leaf you enclosed is of the *Calla Aethiopia*, mentioned at page 113 of our sixth volume. (J. R.).—The crimson flower is *Siphocampylus Surinamensis*, var. *rubra*. The orchid bud was crushed. (Rev. M. E.).—Yours is *Veronica speciosa*; even in Ireland we think it will not do under a warm wall without protection. (H. B.).—No. 1. *Ruscus racemosus*, or *Alexandrian Laurel*. No. 2. *Gazania uniflora*, a greenhouse undershrub. No. 3 is a *Phlox*, but we cannot determine which.

WEEKLY CALENDAR.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last twenty-five years, the average highest and lowest temperatures of these days are 46.2° and 34.1° respectively. The greatest heat, 61°, occurred on the 13th in 1842; and the lowest cold, 11°, on the 13th in 1846. During the period 106 days were fine, and on 69 rain fell.

WINGED TOBACCO PLANT.

(*Nicotiana alata*.)

THIS is a tender annual, and a native of South Brazil. It belongs to the Natural Order of Nightshades (*Solanaceæ*), and to Pentandria Monogynia of the Linnæan system. Like other tender annuals of the same family, the seeds require to be sown early in spring, on a gentle hotbed, and the seedlings, when they have three leaves, to be pricked out into small pots, and kept under the same frame, and to be moved to their blooming place after re-potting in May. We extract the following from *Paxton's Flower Garden* :—

“We translate literally the account given of this plant by Link and Otto. ‘The stem is from four to five feet in height, branching, with distant, glandular hairs. The leaves are from three to four or more inches long, and from one to two inches broad; the upper ones are smaller; they are all decurrent and form narrow wings on the stem, obtuse, and with a small callous point, but a little repand at the edges, and toothed, the teeth having also little callous points, on both sides rough with small somewhat closely pressed hairs, and at the edges furnished with distant and glandular hairs.

The flowers are placed rather far apart from each other on a raceme; the lower pedicels are one inch long, the upper ones are shorter. The rough calyx is not quite an inch in length, tubular; its teeth are long and very narrow. The flowers are white, and sweet-scented; the tube from two to three inches long, a little expanding at the top; the teeth of the limb, eight lines in length, are oval, somewhat expanded, obtuse. Stamens as long as the tube. Style somewhat longer. Capsules oblong. The seeds of this plant were sent by M. Sello, in 1827, from Brazil. They should be sown in the spring in pots, and the seedlings should be planted out in the open ground when the frosts are gone. The plant is hardy, and may be kept in winter in a temperature of from 38° to 43° Fahr, and as such plants as are strongest flower best and produce most seeds, they should be so treated. The soil should be light, but rich, and mixed with sand. The large, white, odoriferous flowers, forming nice-looking tufts, render the plant suitable for bedding-out. The flowers close in the day-time and hang down, but open at night. If the weather is cloudy they open as early as five, P.M., but if clear, not before six-and-a-half, P.M.; in like manner they shut in the morning at six if the weather be clear, but not before seven if it be overcast.’

“Such is the account given by Link and Otto, of a plant which we think is beyond all doubt what Sir Henry Willock found cultivated in Persia, and sent to England as the source of Shiraz Tobacco; in consequence of which it was called *N. persica* by one of us, and, according to M. Walpers, *N. decurrens*, by Bishop Agardh. We must, however, observe that the Persian plant was not observed to be a perennial; nor do the leaves appear to have been so distinctly decurrent as is represented in the accompanying figure: but the specimens which have been preserved show that the leaves were somewhat decurrent, even near the summit of the flowering-stem. This identification of plants supposed to be distinct, leads to the inquiry of how a South Brazilian plant came to be cultivated in Persia as Tobacco? and also whether any Brazilian Tobacco is manufactured from it? We trust that some one will be able to answer these questions, as well as many others connected with the history of commercial Tobacco; as, for instance, is any Havannah Tobacco prepared from *N. amplexicaulis*, as George Don reported? Is the white-flowered Guatemala Tobacco a species distinct from the Red Virginian, *N. Tabacum*? Are the red-flowered Tobaccos all varieties of *N. Tabacum*? or do they belong to different species, as some pretend? What yields the pitchy Tobacco of Latakia; or the mild Tobacco of Syria? The Djebelé seems to belong to *N. Tabacum*. Is it true that *N. paniculata* is cultivated in the East? How came *N. rustica* to be grown in Egypt and Tunis, where it produces the fragrant but strong Tombaki Tobacco, which was shown at the Great Exhibition of all Nations? Of what country is *N. rustica* certainly a native? All these are interesting questions, to not one of which we believe can a satisfactory answer be found in books. *N. alata* is lost in English gardens, but might perhaps be recovered from Berlin.”

It is a paradoxical but explicable Kentish proverb, that “Tenterden church steeple was the origin of the Goodwin Sands;” and we have heard of a shipwreck being shewn satisfactorily to have been caused by the vessel

having sailed on a Friday; but out of five letters, all accusing *Guano* of being the cause of the Potato murrain, we cannot trace even the pretence of a reason, much less of evidence, on which our five correspondents

round their opinion. One of them, indeed, ventures to say, that "it was never intended that such a mass of excrementitious matter should be brought into this country;" and the inference intended thence to be drawn is that the Potato murrain is a judgment upon us for having done so! We must be excused for characterising such an observation as so absurd, that we think the writer, when he remembers that the disease is in a hundred countries where the use of Guano is unknown, will laugh at his own hasty illogical conclusion.

We have no intention to re-enter, at present, upon the subject of the Potato disease, but we have mentioned the subject of these letters that it may indicate why we think it necessary to explain the cause of Guano being so powerful a fertiliser.

It is a fact, which we pointed out in the "Gardener's Magazine" (vol iv. 81), about twenty-five years since, that manures are powerful in proportion to the quantity of ammonia which they contain. Night soil, we then observed, one of the most beneficial of manures, surpasses all others in the abundance of its ammoniacal constituents in the proportion of three to one; and the nearer any animal approaches to man in the nature of its food, the more fertilizing is the manure which it affords. We added our belief that such power of promoting the vigour of plants arises from the stimulating qualities of the ammonia those manures contain, adding, that we had no doubt that a languishing plant, such as orange-trees, as they usually arrive here from Italy, might be aided in recovering by having their stem and branches steeped in a tepid weak solution of carbonate of ammonia, and by suspending an uncorked phial, containing some of the same solution, among its branches when planted. These opinions are strongly confirmed by the recent experiments of M. Ville, published in the "Comptes Rendus."

When we wrote as above, the use of *Guano* as a manure was unknown among our cultivators of the soil; and it affords another powerful testimony to the truth of our opinion, that manures are powerful in proportion to their richness in ammonia. Professor Way has analysed the Guano brought from various localities, and it is certain that in the following list the specimens are superior as manures, exactly in the proportion they excel each other in ammonia.

Peruvian	17.41 per cent.
Icaboë	7.30 "
Patagonian	2.54 "
Saldanha Bay	1.62 "

So powerful are the effects of the ammonia, that about four hundred weight of Peruvian is a quantity quite sufficient for manuring an acre, and of the others, quantities just proportioned to their ammoniacal constituent. This indicates, unmistakably, the importance to the cultivator of obtaining genuine Guano, and he cannot feel confidence that he will obtain such security, unless he purchases from long-established dealers, who have a business to lose if it is proved that they have deceived their customers.

The increasing demand shows that the value of Guano is confirmed by every year's experience; and we hail the fact as a proof that British cultivators, true to our national character, meet increased difficulties by increased efforts to rise superior over them. The quantities imported in the last five years are as follows (*Farmers' Almanac for 1853, p. 21*):—

	1847	1848	1849	1850	1851
Tons...	82,392	71,414	83,430	116,925	243,016

In Guano the allotment-gardener and the small market-gardener have a powerful friend. Want of capital, and of the means of keeping much animal stock, renders a deficiency of manure their chief difficulty, and Guano releases them from it. We have now seen it employed almost for every important garden crop; and we can testify that it helps them to as excellent a growth as would be obtained by applying twenty times their weight of any farm-yard dung. All the Cabbageworts, Spinach, Celery, Asparagus, Strawberries, Roses, and many other garden plants, we have seen grown without any other manure being added, and we can testify that never was a finer produce obtained, even with a lavish expenditure of the gardener's usual compost. Let all gardeners bear this in mind, and whenever inconvenienced by a deficiency of manure, let them remember that they can purchase the best Peruvian Guano for ten shillings per hundred weight.

COVENT GARDEN.

ERE this, our readers will have had time to consider the proposition we made as to the economical plantations of fruit-trees; and taking it for granted that, with some of them at least, it has met with some degree of favour, we continue the subject.

We have already given a list of those varieties of Apples which we would recommend for dessert use, and which are likely to be most remunerative when taken to market. This week we shall devote our attention to those adapted for culinary purposes; and, carrying out the same plan as that on which we set out, by taking them in their order of maturity, we shall now commence with—

1. *Manks Codlin*.—One of the earliest, best, and most abundant-bearing culinary Apples we have. We have chosen this variety in preference to some of the other early Codlins, because the tree is of a very hardy constitution, succeeds well in exposed situations, and is not very nice as regards soil. This being of a small habit of growth, it would be well to graft it standard high on some other variety of vigorous growth, and which would make a stronger stem than the Manks Codlin would if trained up of itself.

2. *Early Julien*.—To many the name of this Apple will be new, for it is not so well-known as it ought to be, and consequently not so extensively cultivated. It is, nevertheless, a variety of some standing. In the appearance of the fruit it has some resemblance to the *Hawthornden*, but is as superior to that variety as the

Hawthornden is to a turnip. Its flesh is firm and crisp, very juicy and brisk, with a very strong and rich balsamic flavour. The tree is a very early and abundant bearer, almost, if not quite, as much so as the *Hawthornden*. It is ripe in the middle of August, and lasts during the greater part of September. It may even be used in the dessert.

3. *Nonesuch*.—This is a very old and very beautiful English apple, and well suited for orchard planting for the supply of markets, as the tree is an early and great bearer, and the high colour of the fruit is very attractive. It is one of the best for preserving, and makes the finest apple jelly. It is ripe in about the second week in September, and lasts during October.

4. *Wormsley Pippin*.—Among all the varieties Mr. Knight raised, we question if he got a better and more generally valuable apple than this. Besides being of a very large size, and first-rate in every respect for culinary use, it is even a good dessert apple, being crisp, brisk, sugary, and aromatic. But perhaps its greatest qualification is the wide range of country for which it is adapted; it being as easily cultivated in Scotland as in the south of England. It comes in use in September, and lasts during October.

5. *Cellini*.—This is a sort, too, which is deserving of greater popularity. It is handsome and beautifully coloured, and of a good size. It is particularly brisk, juicy, and crisp, with that strong balsamic flavour which is peculiar only to some apples. It is in use during October and November. The tree is a strong and capital grower, and a most abundant bearer. We have only just to look out of the window where we are now writing to see a Cellini tree, about five feet high, which this season was as full of apples as it could hold.

6. *Golden Winter Pearmain*.—This is what is known to most people by the name of *King of the Pippins*, which is, in fact, a *decoy name* given to this variety by a London nurseryman, that he might for a time secure the sale of it to himself. This variety is now pretty well known, and is quite an established favourite, especially in Covent Garden and the other London markets. It is a pretty and handsome apple, and is in use from October till January.

7. *Beauty of Kent*.—One of the most magnificent-looking, and one of the best culinary apples which this country has ever produced. It grows to a great size, and is a fine sauce apple. The tree, however, requires a warm and rather light soil. The fruit is in use from October till February.

8. *Dumelow's Seedling*.—There are few growers now-a-days who do not know the *Wellington Apple*. This is it. It is also sometimes called *Normanion Wonder*. It is a very pretty apple, of good size, and exceedingly firm and weighty. It is one of the very best sauce apples, and well known now in almost all markets. The tree is a strong and vigorous grower, and a good bearer.

9. *Winter Pearmain*.—This, for a cottager's garden, is one of the best we know. It will grow almost anywhere and everywhere, is a most beautiful apple, and

the tree is a very abundant bearer. It is an excellent variety for apple-pies, and is one of those which do not fall away to pulp, but which, though ever so well cooked, still retains the form of slices the same as when first put into the pie. It is in use from November till April, and is a good keeper.

10. *Striped Beefing*.—Very few of our readers know, or ever heard of this variety. The sooner they make its acquaintance the better. We have already exhausted our superlatives on the *Beauty of Kent*, otherwise we would have concentrated all on this. It is an immensely large apple, being generally never less than four inches diameter, beautifully coloured, and the most excellent of the best culinary apples. When baked by itself in a tin, or on a plate, which you will, it falls, and gives out a perfect syrup of rich, sugary juice. It is in use from December till May.

11. *Winter Majetin*.—In appearance this very much resembles the *London Pippin*; but the latter, in ripening, attains a yellow colour, while the former may be kept till May or June, and will always preserve its green colour. It is a very hardy variety, and bears very abundantly.

12. *Gooseberry Apple*.—This is a very valuable apple, not only for its long keeping, but its very fine and peculiar flavour, which, when cooked, very much resembles that of the Gooseberry. It is now coming much into cultivation about London for the supply of the markets, and is a most profitable variety to grow. It comes into use in December or January, and keeps as late as June or July.

We have now completed our list of Apples, and here we leave the subject for the present. Next week we shall, on the same plan, furnish a list of Pears.

We announced, some weeks ago, that APPLES must rise in price before long; and now that time has arrived. During the past week, even although the weather has been so bad, and trade generally dull, the rise has been very considerable. Anything like good samples of kitchen sorts made as much as 7s. and 8s. per bushel, and good dessert 10s. We did not observe anything new among them besides what we have already noticed in former reports. There are still, however, plenty of *Blenheim Pippins*, *Alfristons*, *Newtown Pippins*, *Lady Apples*, and a few *Ribstons*. We observed, also, a small parcel of the old *Calville Blanche*, now very seldom seen in this country, but a great favourite on the continent. These were imported specimens. Among PEARS there is not much new, except a few *Ne Plus Meuris*, a very rich and highly-flavoured pear of the very first rank. It was raised by Van Mons, and named after his gardener Meuris. There are also some *Nelis d'hiver*, *Beurre de Rance*, *Glout Morceau*, and very large specimens of imported *Chaumontel*; all of them make from 3s. to 4s. per dozen.

POTATOES are rising very much in price, even common French kinds of inferior quality are making as high as £5 per ton. *Regents*, of home growth, are £7 10s., and every day they are expected to rise considerably higher.

It is the opinion of good judges that there will not be enough to last out the season.

CUT FLOWERS consist of *Chrysanthemums*, *Camellias*, *Chinese Primroses*, *Fuchsias*, *Heliotropes*, *Heaths*, *Roses*, *Yellow Calceolarias*, *Mignonette*, and *Blue Violets*.—H.

GOSSIP.

In a recent number, p. 91, of the present volume, an inquiry is made after *Dixon and Kerr's Ornamental and Domestic Poultry Book*. We have reason for suspecting that Mr. Kerr is an American, who wrote some time since to the Rev. Mr. Dixon, and that the work referred to is merely a reprint of Mr. Dixon's well-known work which we noticed last week, and we warn our readers from it accordingly; for it would be unjust to the original author to purchase what is pirated, if our suspicion be correct.

Even the little island of *Mauritius* has its Royal Society of Arts and Sciences, and we are glad to see that gardening receives no small portion of its attention. At a recent meeting, over which the Governor presided, it was there stated that *grafting* had been successfully introduced by the society's means, and that two hundred scions had succeeded admirably. Twelve new varieties of the *Pine-apple* were introduced. *Sugar*, however, as might be expected, was the principal object, and we must quote on this subject from the Hon. Mr. Rawson, Treasurer-General of the island. He said:—

"A specimen of that which makes the wealth of the colony (pointing to a magnificent cane on the table sent by Mr. Couvois of Black River), of a size such as no gentleman here ever before witnessed, lies before you. It measures eighteen French feet, and contains fifty-two knots.—There is (said the speaker proudly) the material of our wealth and prosperity. Here is, your Excellency, an evidence of the height to which we have attained, a height to which I hope all planters in this colony are aspiring, and which, if most of them are successful in reaching, will certainly place us at the head of the sugar-growing colonies. Sir, and gentlemen, the medal which I hold in my hand was given to Messrs. Webb and Co. for a sauple of the best sugar presented at the Great Exhibition in London. I think I am correct in saying that they are very, very near getting the Council medal for their production, which, had they obtained, would have been evidence of our sugar being the finest that was exhibited on that celebrated occasion. However, they were second, if not entitled to be the first. Here, your Excellency, is the beautiful medal (handing it to the Governor) which was awarded to them, a medal which ought to be an object of pride not only to Messrs. Webb and Co., but to all the planters, and to every man in the community who takes an interest in the welfare and prosperity of the colony. (Applause)."

But the Mauritians, we observe, also have their *Poultry Shows*, and here is an extract from a report of what was exhibited, and with this extract we will conclude:—

"In Poultry, also, there was great competition, and very superior specimens of *Creole-bred* were exhibited; we particularly noticed those of Mr. Douglas (prize), Mr. Richardson, and Mr. Marie. There were also some fancy fowls of great beauty, and some magnificent capons, which, however, were unrewarded by any prize. We must not pass over Mr. Robinson's superior breed of *Rabbits*, which well deserved the prize awarded; nor Mr. Oliver's *Cape Geese*; nor the

monster *Turkey*, weighing, we learnt, twenty-five pounds! What a mine of truffles it would—but we abstain from depicting 'a sight to dream of not to see,' and adjourn the subject till the December show, which, we hope, will abundantly surpass all its predecessors."

THE following is a list of the *Horticultural and Poultry Shows* of which we are at present aware. We shall be obliged by any of our readers sending us additions to the list, and giving the address of the Secretaries.

HORTICULTURAL SHOWS.

LONDON FLORICULTURAL (Exeter Hall, Strand), Dec. 14†.
SOUTH LONDON (ROYAL), Dec. 16.

POULTRY SHOWS.

BIRMINGHAM AND MIDLAND COUNTIES, 14th, 15th, 16th, and 17th December.
CORNWALL (PENZANCE), January 10th, and 11th. (*Secs.* Rev. W. W. Wingfield, Gulval Vicarage, and E. H. Rodd, Esq.)
HONITON, January 12th. (*Sec.* H. K. Venn.)
SALISBURY AND WESTERN COUNTIES, December 13. (*Sec.* T. Pain, Esq.)

† For seedlings only.

RENOVATION OF FRUIT-TREES.

WHEN we cast our eyes around, and when we call to mind what a vast number of fruit-trees we have met with, or heard of, which disease or unfruitfulness render unworthy of preservation if incurable, it seems astonishing that, after all the books that have been written, all the tales told, and all the fruitist's lore made public, as well as the practical observations of a very many years brought to bear on the subject, such should still be the case. But so it is; and we think some service may be done by dealing out another blow or two at prevailing errors, and pointing to great facts committed with the *root itself*; to the due culture of which all pruning and training must ever hold a secondary position.

Let no one suppose that we wish to decry in sweeping terms the genuine pruner's labours; this time-honoured craft must still hold a place in the annals of horticulture; and we look back with a sort of instinctive veneration on some genuine "early Yorks" whom we knew in our 'prentice days, and who used to sally in the "rest-season," knife in hand, with an expression of countenance fully exhibiting an inward consciousness of their dexterity, and of the great importance of their mission. These were amongst the most patient of men. Years rolled past, and still they pruned on with the utmost precision; "spurring back" with all the exactitude of a walking-stick manufacturer. Indeed, we knew of two of these worthies who were first-raters at walking-sticks, and no marvel either. And fruit *might* occasionally be seen on such trees, which was strange enough; the Pears would occasionally take their stand in bunches at the extremities like tassels; and it was noted, as an odd phenomenon, that the Pears generally commenced where the pruner left off! But our present business is not with wall-trees or Pears alone, but to point to root-culture, for the improvement of unsatisfactory fruit-trees in general; and in order to know what we are about, we must attempt a classification of the evils proposed to be remedied.

As this subject will not be disposed of in one paper, we are in duty bound to prepare the interested reader for it; and the following classification of evils will at once show the breadth of the subject:—

- 1st. Aged trees.
- 2nd. Trees weakened by bearing.
- 3rd. Diseased trees.

4th. Ramblers.

5th. Shy kinds.

6th. Gross, or plethoric young trees.

Before proceeding farther, let us point to the causes of these evils; let us give them names, in order to facilitate a due study of the various causes. The principal will stand as follows:—

1st. Soils of improper texture.

2nd. Soils too rich.

3rd. Too much depth of soil.

4th. Ungenial subsoils.

5th. Atmospheric considerations.

In the consideration of faults in *texture*, we have at once the too light, and the too stiff, or adhesive; the first leading to a kind of leanness in the tree, much averse to the production of first-rate fruit, or to a permanency of habit. On the other hand, there are the clayey loams of extreme tenacity; these, by holding water too long, bring on a debility of constitution, equally averse to profitable results.

Soils too rich.—Most of our readers know by this time that much manure is prejudicial to fruit-trees in general, as inducing an overgross habit averse to the production of blossom-buds; and in addition, in the case of trained or dwarfed trees, causing a most unwarrantable amount of labour to the pruner. There are some exceptions: the Gooseberry and the Black Currant will bear high manuring on most soils; and, indeed, a few exceptions exist in the varieties of some of our fruits. Thus the Manks Codling, one of our very best kitchen apples, will succeed in a rich soil, which would drive a Dumelow's seedling or Normanton Wonder wild. But, be it remembered, that this Manks Apple has the peculiar property of producing bloom-buds freely on the annual shoots; which, of course, creates a greater demand on the root.

Too great a *depth* is the next in our brief review of the evils; the tendency of this is to place the tree beyond that wholesome control which has proved of so much service in later years. We are quite prepared to admit, that in the ordinary orchard, where the object is to produce huge and long-enduring trees, which may pass on to our heirs, without either manuring or pruning, that the soil can scarcely be too deep, if sound; or in other words, if waters can pass freely away at that low level. This is altogether another affair from the dwarfed and early-bearing tree of the garden. And as to the merits of the dwarfing system, when duly carried out, what are the results as compared with the former position of affairs? Then the possessor of a little suburban garden might have a huge Bergamot Pear or a Jargonelle, perhaps a Swan's-Egg; and then there would be the great, old Russet Apple-tree, a gnarled old Codlin, &c., &c.; and these being in bearing, he was therewith tolerably content; for on being advised to plant others, it was ten to one some over-zealous gentleman set him at "composts," and give the ill-fated tree fifty per cent. more manure than the objects warranted. But now, in such a garden, it is becoming no uncommon thing to see an extensive collection, and that, too, in a small compass; in fact, as many kinds as the proprietor can desire.

Ungenial subsoils are not the least of the evils connected with fruit-culture; we speak of those which have received no assistance from the cultivator. Wet and sour bottoms bring on betimes all the effects of age on trees, decayed points, boughs smothered with moss, and a generally lean and debilitated condition. No fine and high flavoured or good-keeping fruit can be expected under such circumstances.

Atmospheric considerations.—Of course an artificial atmosphere is not to be expected out-doors; but if we cannot fit the atmosphere to fruits, we can adapt the selection to peculiar conditions. This is a portion of our subject which has never yet received a fair consider-

ation, even by practical men; it is, however, of much importance, and for the last thirty years—during which period this question, as one of note, has constantly acquired strength—we have seen quite sufficient to confirm the opinion, that it will be well for all parties to give it a consideration. If any reader doubts this, let him try to account for the singular and notorious fact, that a given apple, say A. B., which is a staple commodity in one district, should be lightly esteemed in another. It is of no use saying the soil differs. Soils, after all, are not more material as affecting fruits than the very character of the air itself; and that, it would appear, chiefly based on the degree of moisture where-with it is charged. What makes Cheshire so noted for the production of cheese—its soil? By no means. It is produced in this county from all classes of soils: reclaimed bogs, sandy uplands, and the downhill clays. We do not affirm that an equality exists as to its virtues; but this will not weaken the force of our argument. And then the Damson, almost peculiar to Shropshire and Cheshire, where every hedge-row of the cottager, whether on the clays or the sands, has its thriving Damson-trees.

In many gardens in Lancashire, and other maritime counties, it is no unusual thing to see Peach-trees, in the autumn, with most of their young shoots black and perishing with a kind of gangrene. About twenty years since, when Mr. Taylor was gardener to Earl Wilton, at Heaton Park, near Manchester, he made some new borders for Peach and Nectarine-trees, at a considerable expense, and planted them with capital trees of choice kinds. These trees made the most splendid growth imaginable; in fact, too splendid to be safe. I saw them in the month of October, and poor Taylor was quite puzzled about them; for, having lived previously gardener to the Marquis of Ailesbury, at Sheen, near Richmond, he had not been accustomed to the damp and murky skies of our tall-chimney gentlemen. These borders were twenty per cent. too deep, and sixty per cent. too rich, for the circumstances they had to battle with; and had they been planted *above* the ground level (instead of making holes for them), and the soil a simple upland loam from an old pasture, without a particle of manure on it, the probability is they would not have made half the length of shoot. Here, within thirty miles of Manchester, we never lose a shoot this way; the wood ripens as perfectly as though the trees were in a peach-house; but to be sure, our "stopping" practice has much to do with this; we do not produce wood as sport for the pruner's knife. Now it is not a matter of temperature, let people fancy or affirm what they will; of this we are perfectly satisfied. In order to oppose our argument, some might say, How can we alter the conditions of our atmosphere? We answer, you cannot; but you can alter the conditions under which your trees are situated. It is tolerably evident, that in such climes the trees both absorb more from the atmosphere, and perspire much less; indeed, the latter is the most important fact; for without a liberal perspiration how shall those elaborations freely proceed, which are doubly essential to trees from brighter and warmer climes? Thus we find these men insisting on the necessity for flued walls, by which, it need scarcely be urged, the fruit must become much more costly in its production.

It being tolerably evident, then, that the absorption of too much sap from rich and deep soils is the cause of the failure of such trees, the question is, how to avoid this gluttony? We at once answer, Give them less and poorer diet; put them, as our medical gentlemen would say, under a lowering course, if they become gross, by root-pruning or transplanting; for our readers may rest assured that the pruner's knife can *never* conquer such radical evils. Planting high is of the utmost importance in such cases; and if folks *will have* what is termed

a border, let it be above the ground level instead of below it.

Look at the north of Ireland, and, indeed, other parts of that fertile country, and examine the reasons why they cannot produce Peaches, Nectarines, Apricots, &c., like some parts of England. We were in the habit of corresponding on such subjects, some years since, with Mr. Young, then gardener to the Earl of Enniskillen, at Florence Court, where our singular Irish Yew first showed its face; a mere sport from the common Yew. In such correspondence, Mr. Y. used to give extraordinary accounts of the wild and rampant character of such fruit-trees through extreme humidity of air; not for want of warmth. Broad Beans have been quoted as six feet high, and many other things in proportion. To be sure, the want of more sun-light is a great drawback; but here we are met with another reason for the avoidance of a plethoric habit. Mr. Young has, since those days, gone to Natal, on the African coast; and if ever these pages should obtain a footing amongst the descendants of Ham, we should be right glad to hear from him. He will have a very different account to give of that climate.

In a subsequent paper we will give a detail of cases, with their treatment; and such will surely be fitting matter for the dormant season. R. ERRINGTON.

A VISIT TO THE BOTANIC GARDEN, OXFORD.

THIS is the oldest botanic garden in the kingdom, having been founded in 1632. The first catalogue of plants in it was published in 1648, enumerating two thousand species, of which six hundred were English. Dr. Robert Morison, a native of Aberdeen, was the first Professor of Botany; he was appointed in 1669. Of his three next successors little is known. In 1728, Dillenius, a German botanist, was appointed Professor, and the garden was much improved through the influence and liberality of Dr. William Sherard, who bequeathed £300 to provide a salary for the Professorship. On the death of Dillenius, in 1747, Dr. Humphrey Sibthorp was appointed his successor, and he, in his turn, was succeeded, in 1784, by his youngest son, Dr. John Sibthorp, the celebrated author of "Flora Græca." He died of consumption, in 1796, at the early age of thirty-eight, and in his will bequeathed his books and collections to the botanic gardens. The number of species collected from his manuscripts and specimens amount to three thousand. He also devised a freehold estate of £200 a-year to his own University, for the purpose, first, of publishing his "Flora Græca," and afterwards of endowing a Professorship of Rural Economy. The author of the "Flora Græca" was succeeded by Dr. George Williams, who held the Professor's chair till his death, in 1834, when the present occupier, Professor Daubney, took the reins.

I had a longing desire to visit Oxford, for two reasons; first, to make the personal acquaintance of the worthy curator, Mr. Baxter; and then to see, for the first time, the very garden from which the first ideas of the sexual system in plants was given to the world, from experiments and observations made there two hundred years ago, and before Ray or anybody else had given a thought on the subject. The cross-breeder was received at Oxford very differently from the reception given by Dillenius to Linnæus, whose name is immortalized through the sexuality of plants. Within the last few years, Professor Daubney, assisted by Mr. Baxter, the curator, has made great alterations and improvements in the arrangements of this garden, and their plans are not yet finished. I had some notion that the

Professor had a taste for flower gardening, from his remarks when I once conducted him over a fine scene in that style, but I little expected to find a better taste in the disposition of the flower beds here, along two of the principal walks, than is to be seen in a similar way at Kew. The beds in the angles of walks, at Oxford, and along both sides of the walks, in pairs, are in the best style of the art. They are so at Kew, likewise; but there are no beds in the angles of any of the leading walks at Kew, and there is an outlandish taste in placing five or six feet circles immediately behind each pair of oblong beds, which may be from twenty to twenty-four feet long, writing from memory. The botanic herbaceous plants are planted, chiefly, in circles of different diameters, cut out of the grass behind the flower-beds which skirt the walks, and the trees and shrubs are planted in long borders in such a way as to diversify the surface as much as possible, the situation being low, and without any natural undulations.

The grass garden is also in circles cut out of grass, every species having a circle for itself, and the whole bordered with medicinal plants, and the odds and ends are in borders or strips here and there over the garden. All the walls are covered with half-hardy or nearly hardy plants, and some of them are the very finest specimens in that style I ever saw, particularly a very large full-grown plant of *Spiræa Lindleyana*, on a south-east aspect. It was then in seed at the ends of all the branches, and on an average, the flower branches or clusters were from twenty to thirty inches long, and of immense thickness. It must have been the next thing to the Pampas Grass while it was in flower. The plant is a very fast grower, and last year I recommended to have it made into standards, to rival the Stag-horn Sumach; but, for a cold wall, where plenty of room can be given to it, I would plant it next after *Wistaria sinensis*, and before any other deciduous plant that I can now think of. After that I would plant a strong young plant of *Aralia japonica*, about which Mr. Fish put us on the right scent the other day. The *Spiræa* I would train just like a peach-tree, and the *Aralia* I would allow to grow out from the wall, as you see figs sometimes left untrained. I now see clearly enough that this *Aralia* ought to be treated in all respects like a fig, except the close nailing. *Melanthus major* is here, and at Kew, against walls without heat, and is one of the best of the very old plants that one could plant for the beauty and sea-green of the leaves. The flowers are dull, but so full of honey, that at the Cape of Good Hope they use them for tea and coffee instead of sugar. In very hard winters this needs protection, but if the roots are saved they will soon throw up strong young wood. *Smilax Sarsaparilla* is of the same class, and is convenient for training here and there between specimens of larger growth.

The Olive, Christ's Thorn, (*Zizyphus Paliurus*), the Osage Orange (*Machra aurantiaca*), the oak-leaf *Hydrangea*, *Acacia julibrissin*, a fine thing, New Zealand Flax *Convolvulus scamonium*, *Solanum crispum*, a fast grower but coarser and more common-looking than *S. jasminoides*, are all against cold walls here, with Passion flowers, Banksian Roses, and many other less hardy plants, of which they have a large stock. Also two species of a very scarce plant called *Ephedra* (*monostachya* and *distachya*). One seldom sees these two dwarf evergreen shrubs except in botanic gardens; but they are highly curious, and well worth having, as we have no other plants like them except the *Casuarinas* of Australia, or our own British *Equisetums*, or Mare's-tail.

I must also notice the *Fox Grape* of North America, from among this class, if only to second a suggestion that was lately made by an able writer, to the effect

that these hardy vines from North America would make excellent stocks to work our hothouse grapes on, in preference to growing them on their own tender roots as at present,—a very excellent idea as it appears to me.

After the above, I noted a few out-of-the-way plants which are suitable for a wilderness or for rough banks. *Urtica nivea*—a kind of nettle—a large, bushy shrub, with rough, broad leaves, having the underside quite white, and when they are moved about by the wind, they look singular and very interesting. Another one, of the Currant family, called *Ribes ferox*, looks as fierce and wild as a porcupine. Out of all their herbaceous plants, the two which appeared to me to be most suited for a wilderness part of a garden, were *Phytolacca decandra*, the American Poke, lately described, and *Pyrethrum serotinum*, a very scarce herbaceous plant, reaching nine or ten feet high, with stems and leaves not much stouter than those of a Michaelmas Daisy, and bearing large clusters of white composite flowers on the top, the individual flowers being also large, and easy to be seen a long way off. Whoever grows the old *Astelma maxima*, will find a good match for it in this *Pyrethrum*. Among these trees I shall notice particularly the Maiden-hair Tree, *Salisburia adiantifolia*, one of the finest specimens of it I ever saw; it is a tree that will grow as easily as a Thorn-tree, and every one who plants ought to have this one among the first. *Koelreuteria paniculata*, from China, is another of those fancy trees which every one who wishes to excel in gardening ought to plant.

In all the universities here they teach, among other things, an old Roman doctrine, which says, that "it becomes all men who aspire to excel (in gardening, let us say), to labour with their utmost might, not to pass their life" so-and-so, like so-and-so, but to let the rest of the world understand that they, at any rate, shall not be left behind in the race of garden improvements. Instead of planting ten or twenty trees of one sort, people of this caste would rather plant ten or twenty different sorts of trees, if they only knew the names of the best sorts. The *Koelreuteria* is as pretty going to rest, with its deep, yellow, pinnated leaves, as when the end of every branch is in full bloom, on large, loose pannicles, bearing first, small yellow flowers, and afterwards, large, bladdery seed-pods or capsules. The first tree that attracted my notice, on passing the garden-gate, was a full-grown specimen of the true Service-tree (*Pyrus domestica*) loaded with fruit; here is another tree one hardly sees in a day's march. The Manna-tree, (*Ornus Europæus*), a very, very slow-growing tree at first, is a beautiful specimen here, and so with many others, for which I have no room to-day for mentioning them.

There is a wide ditch on the south side of the garden, and a large pond near the bottom of the garden, in the same direction, and it was astonishing to me to see how many water-plants, from the stoves, they contrived to grow in them all the summer, without any more care than at first to fix them in their places. Those who doubt that most of our stove plants cannot be trusted out-of-doors in the height of summer, and through the autumn, ought to visit Oxford to see these aquatics smothering each other with their luxuriant growth.

Of an opposite family of plants, the Succulents, they have the best and cleanest-growing specimens in England, and a vast number of species of the different forms of *Aloes*, *Mesembryanthemums*, *Cuculias*, *Crassulas*, and so forth, but not many of the *Cactus* family. Many of these curious, gouty plants are enough to make one laugh to look at them. A whole row, on an upper shelf, of little, tiny *Mesembryanthemums*, their leaves fringed all round with rows of teeth, and standing in pairs facing each other, like the jaws of so many puppies of all the dog tribes, and all the cats, and other grinning creatures at full play, such as *caninum*, *agninum*, *vulpinum*, *lupinum*, *tigrinum*, *felinum*, *murinum*, *mustellinum*,

erminum; while *obeordellum*, *testiculare*, *muricatum*, *bifidum*, *spinosum*, *rostratum*, *tuberosum*, *moniliforme*, *taurinum*, and a dozen more of such like, put you in mind of all the drolleries in a toy-shop; and the best of it is, that you could put a score of full-grown plants of most of these into a night-cap; that a little thumb-pot is large enough to grow any one of them; that a little water once or twice a-week in summer, and once in three weeks or a month in winter, will do for them; also that silver sand will do to grow them in; but they will grow in anything; then tell me if it is not worth while to go all the way to Oxford to learn this; and yet the best part about succulent plants is not told, and cannot be told to-day. Among these succulents are two which we might call silver plants, they are so white; they are *Echeveria farinosa* and *pulverulenta*, that is, mealy and powdery-looking. There is one plant of the *Socotorine Aloe*, the finest specimen of the kind, perhaps, in existence, it is so perfect all over, so bushy, so healthy, and so heavy, that four men would find it a good pull to raise it into a barrow, and yet the specimen is not bigger than a full-grown geranium at the London shows. Whether it is the air, the chalky soil, or the great attention they receive, I cannot tell; but there is nothing about London which will come near to the succulents at Oxford for vigour, symmetry of growth, and cleanliness. Perhaps *Crassula perfoliata* is as singular as any of the tribe: the leaves of this species might almost be called versatile, that is, they are so slightly "attached to the stem that they may be turned round at pleasure." When Mr. Fish has a week to spare, he ought to look round London, and see where the best succulents are to be had, and, between us, we could make up a fine selection for amateurs who cannot grow any other kind of plants. We could pick up a dozen sorts that would answer for balconies, terraces, and terrace-gardens, better than the more fashionable plants now in use, because of the novelty of the thing, and the little care needed to look after them. Perhaps Mr. Appleby—now that he has a shop of his own—would hunt out for us the best of the pan Aloes, tree Aloes, and other suitable ones from the other sections.

I shall close this section with a *wonder*—a real tree-pink—*Dianthus fruticosus*. I never saw it, or the like of it before: it has a stem as rough and rugged, and as woody as any plant in the garden, and if the shoots and leaves were cut off, no one could make out the trunk from that of an elm tree dwarfed by a Chinaman. Even as it was, had it not been in flower, I could hardly bring myself to believe that it was a pink at all!

D. BEATON.

(To be continued.)

TRIFLES TO BE THOUGHT ABOUT WITH REGARD TO PLANTS IN PITTS, &c.

It is quite possible to have too much of a good thing. The lady, so admirably pourtrayed in a late number, found this to be the case in regard to the abundance of fruit her garden yielded. Overflowing beneficence was no blessing to her! Many, who nobly buffet with the storms of adversity, lose all balance and self-control when the gale of prosperity comes. Nothing but real evils would ever cure the Mrs. St. Clairs of society of their imaginary woes. Necessity is the chief spur to energy and existence. Without it, there may be strivings and splendid realizations among the few, but there would be sloth and sluggishness, mentally and physically, among the many. What holds true of matters in general, holds equally true in gardening. Fine weather is not unfrequently permitted to do more mischief than the storm. A dull, mild autumn and winter will leave more empty pots behind them than an unusual amount

of frost and snow. In the one case, we are lulled into carelessness; in the other, we are aroused into action.

Already complaints are reaching us about having "too much of the good" of a warm, dull, dripping autumn. Cuttings fairly struck, and secured in pits and frames, are already damping off; and where will they be when April arrives? One person has acted so much on the defensive, that the glasses were kept close, to keep out the dull, foggy, moist air; and when he expected to be able to congratulate himself on his wisdom, the moving of a sash showed Mr. Damp in quiet undisturbed possession. A second has kept them exposed night and day, though many have been rotted off by the surface of the pot; and the soil, in addition to losing its nourishing properties, has been lashed as hard as a brick. A third, knowing that growing plants must not be thoroughly dry even in this weather, has wisely told young *blue apron* to examine all; to take out those that are dry, and water and replace again when drained; and, on his future inspection, he has the pleasure to perceive that the bottom of his pit, so dry erstwhile, is now as thoroughly soused as if a canal from the Nile had been introduced for irrigation. And here, fourthly, is our friend, *Present Time*, chuckling with glee over what he calls, "the stunted rusted things of neighbour *Look-before-him*," who beat him, it is true, last season, but let him look out for the next! "Why, his plants have not budged since October; while mine, from the attention and *heat* I have given them, have grown several inches, and the leaves are as green as leeks." Hint that there may be such a thing as extension, without much addition, and you will be met with a stare, that is designed to tell you, that surely, if great men have found out that *plants are increased greatly in bulk when the leaves are gone*, he cannot be wrong in coming to a similar conclusion when his leaves get fresher every day, and a measuring rule tells him how his shoots lengthen by inches. *These*, and many more cases, I will endeavour to meet in a few directions.

1st. *At all times, but especially in winter, let all stimulants to growth be in proportion to the presence or absence of light.*—It is somewhere about eighteen years since I sent an article to "Loudon's Magazine," disapproving of a high temperature in hothouses at night. Opinions held then have been more than confirmed since—though then I had plenty of reasons, theoretical and practical. The mentioning of these in detail would occupy a number. Let me glance at one or two. In circumstances, as respects heat and moisture favourable to growth, I kept an account of measurements, taken several times a-day, of quick-growing plants. I found that when the night temperature was at all high, increase in length chiefly took place during the darkness of night. The next greatest growth, as respects length of shoot, took place in dull, shady days. In bright days there was always a difference, as respects mere progression, in the case of one plant kept shaded and another fully exposed to sunlight. I perceived, however, that the plant with most light soonest arrived at maturity, bloomed best, and was less subject to casualties. I also found that in the case of such plants grown fully exposed to light, and with as low a temperature at night as to be safe; and, again, of those with a rather high temperature at night, or somewhat shaded during the day—when equal weights of similar-looking shoots were taken from plants thus differently treated, and exposed, first, to the evaporating influence of a dry, heated air; secondly, to being burned in an open vessel; and, thirdly, charred in a somewhat close one—that in every case the hardy light-treated plants produced the heaviest weight of residuum. Then I came to the conclusion, that there might be mere elongation and expansion without much *addition*, on the same principle that out of a small piece of brass the clever worker will manage

to spin out many yards of wire. Exceptions there are, arising from the peculiar nature of particular plants; but, as a general rule, our young friends will do well to bear in mind, that the shining of the sun on the leaves is necessary to solid additions.

What care, then, is necessary *now* for plants in frames and pits, after such a season of warm, dull, muggy weather. Do what could be done, there was too much of the wire-drawing as respects growth. Every thing should have been done, and must continue to be done, to prevent mere elongation, by keeping the plants as *dry* and in as *low a temperature* as to be safe. In general cases, there has been enough of moisture in the *air* to supply plants in such places without watering the roots; and if, during a week's gloom, an hour's sunshine should flag the foliage, it would be advisable then to dew the foliage with a little water, instead of drenching the roots. The very flagging, in such circumstances, speaks of an enervated state of growth; and frequently, when the sun breaks out on a sudden, plants, rendered tender and watery by dull weather, will be most benefited by a slight shading, removing it, however, as soon as it can be done without. On dry days the sashes should be wholly off, when the outside temperature is 40° and above. No rain, however, should fall on the plants, as the moisture, when close, would increase the elongation. In misty weather keep the sashes on, but let air permeate freely beneath them, back and front; taking it away only at night, when there is danger from frost.

2. *Prevent damp from attacking and spreading.* No better weather could have been chosen for the attacks of this insidious enemy. Wherever the plants, in addition, have been kept close and warm, the slender shoots present another favourable circumstance. A low temperature, and abundance of air, as detailed above, are the chief preventives. But even these will not be sufficient. A few decaying and damping leaves left alone will soon spread their contagion. Cleanliness must, therefore, be duly attended to. Not a decaying leaf should stand a day. All the fungous damps delight in garbage. Then the moving of the plants will be a great advantage. You can then roughly rub the outside of your pots; place fresh dry ashes, saw-dust, or boards, for your plants to stand on. Remove a little of the old surface-soil, and fresh dress with dry sandy soil well mixed with powdered charcoal. In delicate cases, a little of this powdered charcoal, mixed with dry sand, and a little, *very little*, powdered lime, and sulphur, may be scattered or puffed among the shoots and leaves. If the frame or pit is deep enough, a raised stage will be a great advantage, more especially if there are means for letting in air, front and back, *beneath* the stage, as well as *over* it by tilting the sashes. In extreme cases, lumps of unslacked quicklime will help to dry and purify the atmosphere. In foggy weather, and there is no artificial means of heating, a few bottles of hot-water, corked, will tend to set the air in motion.

Are all plants usually preserved in such places equally exposed to injury? No. The whole group of Geraniums will suffer little, unless unduly elongated by close heat, and dull weather. Verbenas, Anagallis, Petunias, Senecios, and all of that soft tribe, are easily ruined, and hard-wooded plants are easily mildewed. All the Calceolaria group will suffer little from damp. Half of young beginners ruin *them* by kindness, and a dry atmosphere. If nicely rooted, or commencing to root, they want nothing more during the winter, than to be kept from frost, have plenty of air, and a dusting from the syringe in fine sunny weather.

Suppose we want these plants chiefly for baskets and balconies next season, should we pot them singly in autumn in small pots, put several in a larger pot, or allow the young plants to remain in the cutting-pots? Any way, according to your conveniences, the size you

wish your plants to be, and the state of forwardness in which the cuttings are. Plants in small pots are liable to all extremes, and involve additional labour in routine attention, and any moving they require. When left in cutting-pots, the young plants should be chiefly round the outside, and thus the surface soil can easily be stirred and renovated. When struck moderately early, I prefer placing a number in largish pots, as they are less liable to extremes, and more quickly moved. But for all such stock purposes in winter I approve of wooden boxes—say from two to three feet in length, from nine to twelve inches in width, and from four to seven inches in depth. Any spare boards may soon be converted roughly into such a purpose, and if they have a good painting with quicklime, and be allowed to dry before using them, damps and funguses will trouble them little that season. The chief advantages are—that from the non-conducting properties of the wood, the plants are not exposed to the extremes of heat and cold, dryness and moisture, which they are liable to in small pots, and thus necessary attentions are *minimised*, while all labour in moving from place to place is abridged,—a matter of no little consequence where a limited portion of glass is made subservient to many purposes during the season. When economy in labour becomes a still more serious affair, I shall expect to see, for all out-door ornamenting purposes, with tender plants, pots, and boxes, too, entirely dispensed with, and the requisite number of small plants pricked-out into beds in autumn, there to remain until wanted in the following May.

3rdly. *Watering*.—This has been already alluded to. So few will require anything of the sort, that they had better be removed, watered, and replaced when the extra moisture has drained away.

4thly. *Protecting from frost*.—We have had a few touches of this, and must expect more. Plants in general are in the worst position for resisting its effects. Even under the hardest treatment, the last six weeks has filled them with crude juices, along with a deficiency of solid matter. It is good, therefore, to be prepared. Those who have acted according to the advices of this week would have the plants near the glass. Unless these were on a stage, so as to have several feet of air beneath them, the nearness to the glass, though beneficial in fine weather, would be equally prejudicial in a sudden frost. When there is the smallest likelihood of the *icy king*, it is best to cover the glass at night, even though it would be advisable to leave half-an-inch of air behind. In such circumstances, several degrees of frost would not do much injury, as radiation would chiefly proceed from the glass, or its covering. But near the glass, and not covered, tender, spongy shoots would suffer much from a few degrees of frost. I have hitherto made as simple as I could the whole theory of protection. I could add nothing were I ever so willing. I was told by a person lately, who had read these remarks, that he had built a six-light pit, sunk it two feet in the ground, and left two rows of out-jutting bricks on the back and front wall, so that he could place plants in the bottom, or on transverse platforms of boards, near to, or nearer the glass; and that he meant to have a regular tarpaulin to keep all his glass dry at night in winter, with a softer cloth to lie upon the glass, and to have hay, &c., on it, and beneath the tarpaulin in rough frosty weather. And how could I do other than approve. He rates me, however, that his plants are *damping*, even though he has *dung linings* round the walls; and that the water stands in the bottom of his pit like a canal. Reader! have you any desire to have such a pit; and, for the sake of neatness, and great ultimate economy, do not grudge a little primary outlay? Then build as our friend has done; only have hollow walls if possible, and then they will need no protection; and if not, tie

on them neatly for the winter months, a two-inch layer of wheat-straw. Concrete the bottom of your pit to prevent damp rising; for you have no business to put water there *now*, and a little in summer will be rather an advantage. Raise the earth round the outside of the walls of your pit, so that when beat or rolled firmly there will be a slope outwards of at least one inch to the foot; cover this to the width of six feet with one-eighth-of-an-inch in thickness of coal tar; over that place a layer of gravel firmly rolled, and you may defy outside moisture finding its way within; and then, for protection, tack a lath to the side of every sash—to be removed in summer—and have light half-inch deal wooden shutters, well painted, made to slide up on every sash: and though for such covers for six ordinary lights you pay the best part of two pounds, with ordinary care they will be little the worse for twenty years' wear, while they will enable you to dispense with all other protecting material, except a little litter thrown over them in *very severe* weather. The laths round the sash are both to prevent the covers wearing off the paint, and to enclose a body of air between the glass and the cover. Who, that prides himself on being an amateur, would not prefer examining his pets in cleanliness and comfort, instead of wading among rotting filth and littery, dripping mats?

The same principles will apply to pits and houses heated and used as *Preservatories*. The labour and attention is, however, considerably abridged, as in the dullest, closest weather a sharp fire in the morning, with plenty of air, will promote a free circulation, and thus so far put a damper on damps. Keep in view, however, our first directions.

R. FISH.

CONSERVATIVE AND HEATED FRUIT WALLS.

A CORRESPONDENT (F. H.) writes thus:—"Observing in THE COTTAGE GARDENER that Mr. Appleby remarks upon the Osmaston Manor Garden, and mentions that the garden-walls there are heated with hot water, and answer well, I should feel obliged to him if he would answer the following queries:—

"How large is the boiler? What length of pipe to one boiler? What is the diameter of the pipes? What height is the wall? And are there any gratings in the wall?" Our Editor very naturally sent me these queries to answer; and in order to be quite correct, I sent them to my friend Mr. Lamb, the gardener at Osmaston, and with his usual prompt kindness I had, by return of post, the following answer:—

1st. "The boiler is composed of a series of pipes three inches diameter, connected together at each end; thus forming a boiler seven feet long, which is placed over the fire. 2nd. We have upwards of 3000 feet of pipes to one boiler, but intend to connect another powerful boiler, to be used if found necessary, as there is more pipe to be added. 3rd. The pipes are principally four inches diameter, except the flow and return near the boiler; there they are five inches diameter, in consequence of there being many connections. 5th. There are no gratings in the wall. The walls are about twelve feet high." Mr. L. adds in a postscript, that if any further description is necessary he will be happy to give it. So I would advise F. H. to write to him personally. This correspondence is just the thing that is really useful to such parties as may be about to build garden-walls, either for fruit, like those of our correspondent and the Osmaston gardens, or for growing ornamental plants against, usually called conservative-walls, though, I think, *preservative* would be a better term.

Heated walls have, as is well known, been used for a long period. I well remember, when I was undergardener at a place in Yorkshire (Wheatley Hall, near

Doncaster), what a toil and turmoil the attending the fires was to a young man. The head-gardener would come round with his lantern some cold night in March or April, feel at the wall, and if it was too hot or too cold, would he not storm away at my carelessness! I was young then (it was my first place), not more than seventeen, and could not understand the consequence of too much heat or too much cold to such, as I considered, hardy things as Peaches and Apricots. He was a gardener of the old school, and grew some as fine Peaches as a Snow, or a Collinson, or any other good gardener of the present day. He was a strict disciplinarian, and I never forgot his lessons. His name was Mr. B. Mann, and is worthy of being recorded, for he was a worthy man, and filled the situation for more than thirty years with credit. The walls, I need not say, were then nothing but smoke flues, winding upwards in length of about fifty feet to each fire; so that it was no trivial affair to attend to ten or a dozen fires during the season. Science has done much to ease the labour of the under-gardener. Hot water has not only lessened the extreme labour, but has rendered the necessary attention more certain in its results. One fire, as in the case of the hot walls at Osmaston Manor, is more easily attended to, and the heat is far more equally diffused throughout the entire length of the walls, to say nothing of the great saving in fuel. In my younger days, the idea of devoting a wall to the growth of half-hardy plants would have been thought a most extravagant idea, something like a steam railroad; but now! no garden of any celebrity but must have its conservative-wall. Perhaps the finest example in Great Britain is the one at Chatsworth. I have observed the progress of that wall with great interest. When the idea of growing half-hardy plants against a wall was first acted upon by Sir Joseph Paxton, perhaps nothing more was aimed at than a trial of the cold which certain plants would bear if sheltered by a wall in about the same degree as gardeners shelter the more tender fruits; and the success of the first attempt led to the present splendid example. The wall now extends to the length of several hundred feet, is covered with glass, which extends a sufficient distance to allow walking under it. The plants thrive beautifully and flower magnificently. There may be seen *Oranges* and *Camellias* in the greatest possible luxuriance, the former blooming and fruiting freely, and the latter flowering profusely; also great numbers of New Holland plants, such as *Acacias*, *Epacris*, *Hoveas*, &c., &c., growing so well, and blooming so gaudily as almost to be unrecognisable. I had the pleasure of seeing this famous wall this last August, and a more interesting and beautiful sight in gardening I scarcely ever witnessed. One plant, the *Ribes speciosa*, was particularly gorgeous. This plant is undeservedly neglected, very few gardens possess it at all; yet there are not many plants that are grown against a warm wall that surpass it in beauty when in bloom.

There is, also, a tolerably good wall of this description which was planned and planted by the same able garden architect (Sir J. Paxton), at Tatton Park, near Knutsford, in Cheshire, one of the finest seats in that fine county. It belongs to W. Egerton, Esq. Another wall of this description was mentioned incidentally by my good friend Mr. Fish. He saw it at Wrest Park, and promised to describe it. I trust he will not forget, as the subject of conservative-walls, I assure him, is becoming one of the forward moves in gardening. I saw, on my late journey, many instances on a small scale indeed; but still the idea, and desire to carry out the idea, is progressing; so that any information any of us can give on the subject will be acceptable. I shall try to do my share, and propose to myself to ask and try to answer the following questions. What is the use of a conservative-wall? What is the best aspect? How

should it be built or formed? Should it be heated? Should it be covered with glass? And lastly, What kind of plants should be planted against it? and then give a list of such plants as would be suitable for the purpose.

T. APPLEBY.

(To be continued.)

THE PANSEY.

AMONGST the various tribes of florists' flowers, there are few that attract more admiration than the *Pansy*. It possesses many points of beauty, both in form, colour, and length of blooming season. We find it at all the spring and summer exhibitions, both as cut blooms, and flowering in pots. It is a favourite throughout the length and breadth of the land, and is cultivated largely by almost every florist. As one proof of its general cultivation, I have received a list of kinds or varieties grown by a gentlemen so far north as Berwick-upon-Tweed.

The readers of THE COTTAGE GARDENER, AND GENTLEMAN'S COMPANION (and a very good companion, too, in his garden), will recollect that I invited florists to send me a list of such varieties as they considered first-rate in quality. My Berwick friend was the first to respond to the call, and, in consequence, I send a copy of the list to the Editor. I have no doubt it will be received gladly by our readers, and will be useful to many amateurs, and even dealers. I can vouch for the accuracy of the list, and for the qualities the writer describes.

WHITE OR STRAW-COLOURED GROUNDS, WITH MARGINS OF BLUE, LILAC, PURPLE, PUCE, &c.

Almanzor (C. Mc Laurin); white and purple; a good old flower.

British Queen (Dickson and Co., Edinburgh); white, and fine bluish-purple; beautiful eye; new.

Boadicea; white, upper petals dark purple, belt same colour; very distinctly marked; new and fine.

Countess of Roslin (Downie and Laird); beautiful; straw and rich purple belting; new, and extra fine form.

Duchess of Rutland (Thomson); white, with lilac belt on the top petals; fine.

France Cycle (Grieve); white, and rich deep purple; fine form.

Lady Mackenzie (Stirling); upper and lower petals dark blue, centre very pure white.

Lord Hardinge (Gossett); straw, and bright puce.

Lord Jeffrey (Lighbody); white, deep purple belt, and top petals the same colour; good velvety substance.

Hunt's Helen (Hunt); white and light purple; a fine flower, but sometimes comes indistinct in hot weather.

Mrs. Beck; white centre, rich purple belting; fine eye; extra fine form.

Miriam (Dickson and Co.); white, broad belt, and top petals of the richest dark purple; good substance; fine form; eye large and very dense; new, and extra fine.

Miss Talbot (Dickson and Co.); white, belt and top petals deep purple; new and fine.

Minstrel (Dickson and Co.); white, belt and top petals blue-purple; new and fine.

Royal Standard (Dickson and Co.); white, belt and top petals of a beautiful light purple; new, and extra fine.

Royal Visit (Dickson and Co.); light primrose, and rich deep moreen top petals and belt; good.

YELLOW GROUNDS, WITH MARGINS OF BLUE, LILAC, PURPLE, MAROON, &c.

Captivation (Major); yellow, belted with rich, dark maroon; fine.

Commander-in-Chief (Youell); yellow-bronze, purple margin.

Constance (Thomson); yellow and purple; very constant.

Duke of Norfolk; yellow, and deep maroon; apt to run in summer, but a noble blower when in perfection.

Elegant (Thomson); yellow, and deep bronzy-purple; fine.

Gliff (Dickson and Co.); yellow, top petals and belt fine bronze; large size (has been three inches across); good substance; new and extra fine.

Jubilee (Dickson and Co.); yellow, fine bronze-pace belt and top petals; form and texture very fine; new.

Lady Emily (Sheare's); yellow and bright claret; large and constant; new.

Mr. Beck (Turner); yellow and maroon; good old variety.

Post Captain (Maishment); yellow and bronzy-purple.

Sunbeam (Dickson and Co.); rich, deep, orange-chrome margin, and top petals bright bronze-erimson; blotch large and dense; constant and beautiful.

SELFS.

Adela (Turner's); golden-yellow; large and fine.

Blanche (Turner's); large, white, fine, bold eye.

Duke of Perth (Handyside); very dark; fine and large.

D'Israeli (Hunt); very deep purple, with a shade of blue.

Flower of the Day (Downie and Laird); rich dark plum; bright golden eye, with a fine, white crown; round and good; new.

Lucy Neal (Scotcher's); dark purple; fine.

Magnificent (Neilson); shaded puce.

Satirist (Thomson); bronze; quite a distinct flower.

St. Andrew (Downie and Laird); rich, dark mulberry; of perfect form; new; and a first-rate show flower.

Sovereign (Dickson and Co.); a golden-yellow self; blotch large and dense; new; large and fine form; one of the very best yellows.

Uranus (Dickson and Co.); yellow; large and fine.

My correspondent says, "I consider the above the very best Pansies grown in this neighbourhood; the greater part I have myself, and therefore can speak from experience; the remainder I have had opportunity of seeing in flower, so they may be depended upon as being first class. I do not hesitate to say, that a well-grown bloom of any of them would be an acquisition to any stand."

Such lists as the above, from distant parts of the kingdom, are exceedingly interesting. Many of the varieties, I think, would be desirable to the florists of the south; and the florists of the north will be pleased with a list of the best flowers grown in the south. This list it shall be my business to furnish in my next paper; the space allotted to me now being full.—T. APPLEBY.

(To be continued.)

COAL ASHES AS A PRESERVATIVE TO CELERY, &c.

THE dark days before Christmas being proverbial for their decaying influences, means must be taken to counteract their destructive tendency. It usually happens that the protracted dull and damp weather has the effect of injuring all herbaceous growth, in which the vital powers are not in full and vigorous action: for instance, celery that is full grown begins sooner to decay than the younger or later-planted section—the former having attained a degree of ripeness, which, like maturity in all other cases, is sooner or later followed by decay. To maintain the one and arrest the other is an important duty of the horticulturist. The enthusiastic florist acts in accordance with this principle when he shades his beds of tulips, or other pets—he thereby retards nature's operations in the various functions necessary to the

production of seeds, as well as the ripening of the bulb, or other portion of the plant. The shutting out of sunshine is the means of his retaining in perfection that part of a plant's formation to which he has attached the name "beautiful." Now, though the principle is the same, wherein a plant is preserved entire against decay arising from another source, yet the means to be adopted are so different, that it is only in a literal sense that they agree. The tendency of summer sunshine being to hasten plants on, to accomplish that purpose destined them by nature (namely, to ripen and perfect their seeds, in order to perpetuate their species), is another thing from the hardship of winter acting on a plant of mature growth rendered delicate by artificial cultivation, by which term Celery and Endive may justly be known when they have undergone the process of blanching, which process, by-the-by, is accomplished at the expense of the plants' constitutional hardihood; and though they may occasionally live and prosper after undergoing this debilitating operation, yet, in many cases, they die before the return of that stimulating season which recalls their dormant energies to activity again. That a great number should perish under the ordeal they have been subjected to, need not be surprising, when we consider that the process is all but total destruction at once to the plant. This may appear strange, but it is true; it is only those parts of the plant left to enjoy the action of the atmosphere that keep the others alive: to totally cover all would be a more speedy death than the protracted one, wherein we make the plant part with some of its juices, which we reject as unpalatable; and having done so, we need not be surprised at the loss of health which the plant has sustained in the trial. Productions less robust would have perished under it, but Celery resists decay more than most things, though its endurance has limits; and the earliest "full blanching" of the season will be the first to decay, while the later grown will keep better, and do to succeed it. But then the question is, how is the season of the first-named to be prolonged? how is its decay to be arrested? The question is an important one, but its solution lies in a nutshell. Celery, as well as everything else, is preserved a longer or shorter time in exact accordance with the medium by which it is surrounded; should the medium consist of putrid matter, wet and sour, its contagious qualities may easily be guessed at; if, on the other hand, a good, dry, anti-decaying material be used, a contrary result will be the consequence. Now, I do not use the word dry in the sense it is accepted as a fireside term, because it is folly to think of anything keeping dry that is in contact with the ground, should there even be a waterproof covering over it, loaded as the ground is, as well as the atmosphere, with moisture at this season. It is, therefore, useless to suppose that the term "dry" has any further meaning than as a substance absorbing less water than most other things by which it is surrounded. Ground of a certain description is called "dry," although exposed to every shower that falls. The fact is that by conventional usage we have accustomed ourselves to call it so, because this same rain is, by the component parts of such ground being so open, so speedily carried off, that it is, comparatively speaking, drier than soil of a contrary kind; consequently, we will take it for granted that this porous sandy soil is better adapted to blanch and preserve Celery than the deep loamy kind, strongly impregnated, as it often is, with humous, and other putrid or absorbing matter; but then, many gardens consist entirely of this latter description, which though not the best for blanching this vegetable, is certainly the most suitable for growing it.

Now, it is no difficult matter to grow Celery in one substance and blanch it in another, and many have been the means used to comply with this latter suggestion.

Earthenware tiles or pipes, whole and in halves, have been recommended, and used with more or less success: straw and other bandages have also been tried by some, but the result here has not been satisfactory, affording as it does such an harbour for slugs and similar enemies, it has another bad property also, that of beginning to rot just at the precise time when it ought to preserve itself unimpaired; and by its decaying when the plant is less able to resist its contagious influence, the evil produced is badly compensated by its former utility. Straw, moss, and other litter, is, therefore, to be avoided, and something else substituted. I have myself, after many trials, found nothing so useful as plain coal-ashes; their porosity is such as allows but a small quantity of water to loiter amongst them, compared with other things, while they have a sort of anti-decaying influence in their having so recently passed through the fire, and the way I use them is this—when the celery requires earthing-up, a quantity of ashes is thrown against it by a person on each side of the row or trench, whilst a third one holds the leaves of the plant together; the ashes are then backed-up with earth, and the process repeated when necessary; by this means, no more ashes are used than requisite to enclose the stalk a few inches on all sides with this keeping substance, observing that it is essential that the ashes last of all should be at the summit:—beating the sides of the embankment so as to throw off the wet, is also advisable; but except in very severe, hard frosts, I do not recommend the use of straw, or any other loose covering at top:—it would, doubtless, be better, if the plants could be entirely protected from rain; but since that cannot be, I have little faith in loose straw, or other litter, doing much good that way. Certainly it will exclude frost, and for that purpose it is valuable; but remove it in rainy weather, or the covering up of that part of the plant which has maintained vitality in the wet, will be its utter destruction sooner than it would otherwise be. Another property that coal-ashes have, is the repulsive medium they present to worms and other depredators that prey on the celery when it becomes fit for use; the sharp, gritty feel that it has, together, no doubt, with some obnoxious quality imparted to it in its combustion, makes coal-ashes but little desired by the tribe of enemies the Celery suffers from. These qualifications, united together with their cheapness, and, not the least, their utility in stiff, heavy lands afterwards, enable me to recommend them to the amateur with more confidence than anything else in that way that I have tried.

J. ROBSON.

DAHLIAS OF 1851.

My remarks on the new Dahlia seem to have given pleasure to some of your readers. I proceed, therefore, to fulfil my promise respecting the Dahlias which came under my notice last season. I shall begin alphabetically, so as not to appear invidious, though I dare say I shall offend some of the vendors. If I do, the only revenge I recommend to them, is more care in sending out, and I believe many of them really are desirous of doing right. Let me begin with noticing another fact I have proved, which is, that owing to so many plants being propagated from the roots, and that after being sent out by the advertizing party, the plants have again to undergo decapitation; and after losing the side-shoot, so as to make three plants out of one, the poor amateur gets a chance of blooming his half-guinea plant about the 20th of September! To avoid all this, let every amateur send to a respectable grower in April, with orders to have his plants the first week in May, or not at all. That is my plan.

Another important matter, is to know how to grow your plant when you have it. I will give you my experience. Repot your plant as soon as you receive it, and keep it growing, not in much heat, but with plenty of air. A *nearly-*

spent dung frame, giving only a *little bottom-heat*, is best, just to *swell* the plant, and not let it spindle up. Plant out, the 1st of June, six feet apart. Never cut off any branches, but tie out the shoots; and if they are many, remove them when very young, *but never cut off branches*. I saw some plants this year which appeared like stalks of cabbages, with a few blooms on the top. My plan is to top the young plant, and then the shoots will bloom well by being thinned out, and the centre bloom is generally semi-double. My plants, this year, almost met together, and none above four feet in height, except *John Edward* and *Fearless*, which are very tall growers. This I consider was derived from watering every night *over-head*, not round the root. Just try this, and see the effects.

I begin my remarks with

ALICE (Drummond's); fine colour; in almost every case semi-double, and did not have a good bloom all the season.—*Discarded*.

ALERT (Barnes'); long petal; very thin; dull colour; good eye.—*Discarded*.

ARIEL (Turner's); white; not one good bloom all the season; good colour.—*Discarded*.

AURORA (Keyne's); dull colour; sometimes very fine; hard eye; requires much water. I think I shall try it again.

ANNIE SALTER (Salter's); *peach, like wax*; one of the best flowers I ever saw; requires no cutting out; very free bloomer, and every bloom on the plant I grew fit for show; first-class show flower; rather late; and a good large plant. Should be put out.

ABSALOM (Spary's); amber; pretty colour; rather thin; and late in the season. I had a bloom or two pretty good; shall try it again.

CLOTH OF GOLD (Hooper's); dull colour; very bad.—*Discarded*.

COMPACTA (Gaines'); buff-scarlet; very small; dull colour.—*Discarded*.

DR. FRAMPTON (Rawlings'); very pretty, and fine form. I never had a bloom large enough to show, but I had some very perfect flowers. It must be very much thinned. Shall grow it again, and try hard to get it large enough. Smallness is its only fault.

DUCHESS OF SUTHERLAND (Turner's); fancy purple and white; too thin and uncertain.—*Discarded*.

DOUGLAS JERROLD (Keyne's); this I have seen very fine. I fear it is uncertain; but when caught, it is quite a gem. Owing to its tip, the form is not good and not bearable, except when it has the tip. I shall try it again. Colour buff, with scarlet tip. I remember seeing some blooms good at Surrey Gardens. Cut out the plants by thinning.

EDMUND FOSTER (Turner's); crimson; very full; coarse. I do not like it. Flower round, but not symmetrical.—*Discarded*.

EVENING STAR (Salter's); good colour; thin; poor.—*Discarded*.

FLORA McIVOR (Keyne's); purple, tipped with white. This flower was a gift, and proved a good one. It is very fine, and first-class; fancy flower; not cut out; grows strong.

GLORIE DE KAINE; lilac, black and white striped; a very beautiful flower; good form, and first-class; very certain; grows well.

GLOBE (Turner's); bronzy-brown; new colour; good form; uncertain, but sometimes good. I shall grow it again. Requires cutting out, and good growth.

GRAIN D'OR; orange; dull colour; not symmetrical.—*Discarded*.

GEORGE WILLIAMS (Union); rather thin; good smooth petal. I shall try it again. My plant was very poor, and had no chance of seeing it until late.

JAUN DE PASSY; pale yellow; beautiful colour; very full, but not quite right at the finish; a good flower for the garden, but not for show.—*Discarded*.

JOHN DAVIES (Cook's); not so good as *Cobden*; too rough, and not shaded.—*Discarded*.

KOSSUTH (Drummond's); fancy; not good enough.—*Discarded*.

LOUISA GLENNY (Rawlings'); yellow; one of the finest for form and colour. I grew two plants, one of which gave me all show flowers, the other not one. Requires cutting out. Shall try it again, for, when right, I have seen no yellow equal to it for form.

Laura Lavington (Keyne's); fawn, tipped with white; very fine-formed flower, but came many selfs, and not tipped. Perhaps the season was against it; at all events, it must be grown; we have few such good forms among the fancies yet.

Lilliput (Barnes'); red, tipped with white; very fine, fancy flower; requires cutting out; was very late with me, but first-rate when grown well.—OBSERVER.

(To be continued.)

CUCUMBER PIT.

a, the soil; *b*, trellis; *c*, stage for ferns; *d*, stage for ferns, with water-tank under; *e*, hot-water pipes; *f*, brick pillars, to support the slate box; *g*, pipe for admitting fresh air; *h*, pipe for the escape of foul air; *i*, ground-level; *j*, steps by which you enter the pit; *k*, passage; *l*, the wall is built hollow here.

THE above is a plan of our Cucumber pit, which we have now had at work for fifteen months; and as it answers the purpose so well, I thought it worth a corner in THE COTTAGE GARDENER. The pit is forty feet long, four lights of which are devoted to Cucumbers, and the other six for Kidney Beans, both of which I send to table all the year. The soil which I use for Cucumbers, is one part of loam, dug from the pasture, not more than three inches deep; one part leaf mould, and one part old hotbed dung, to which is added a small portion of soot, mixing these well together. When sufficiently dry, it is put into the pit, first draining with bones, over which I put the roughest of the compost. In a day or two the soil is warm enough to receive the plants, which have previously formed three or four rough leaves. I always plant them two inches deeper than they were before, and fill in round the stem with charcoal, as that prevents canker. I find it best to have only one plant to a light, as the Cucumber thrives best with plenty of room. The leading shoot I train up the centre of the light; never stop it till it reaches within six inches from the top of the light, but the laterals which are sent out are stopped at the second joint, and trained out at right angles, exactly the same as a vine managed on the spur system. They very soon break from the second joint, at which time, and always afterwards, they are never let go more than one joint at a time, taking care in stopping not to injure the fruit, which is as yet almost imperceptible. All the male blossoms I take off, as they are of no use, except seed is required, and I never allow any fruit to be produced till the leader has reached the top. I always use water at the same temperature as the soil, which is 75° to 80°; and when I water, I give a thorough soaking, but not again till it is really required, using liquid-manure every alternate time—poultry dung is the best for that purpose, taking care not to make it too strong. The air pipes *g* and *h* are always open day and night, except in very sharp weather, when *h* is closed. I ought to mention that there is one of these pipes under each light. Of course, in very hot weather, the lights are

tilted up at the back; but it is better, in the winter months, to allow the temperature to rise a few degrees than to open them too much for a "blink o' sun," as that, in all probability, would make the plants flag, which is sadly against their well-being. The night temperature I prefer is 60°, and in the day 70°, and 80° if from sun heat, with plenty of moisture often charged with sulphur, as that keeps mildew at arms-length. If this meets your approval, I will trouble you very soon again with a plan of a flower-garden, and also an American ground, accompanied with a few suggestions.—J. RUST, Gardener, Chase-Side-House, Enfield.

WINCHESTER AND SOUTHERN COUNTIES' SOCIETY'S EXHIBITION OF POULTRY.

CLOSELY following on Dorchester and Hitchin, Winchester has now added another name to the list of those towns and districts which have this year initiated themselves in the establishment of societies for the improvement of the various breeds of domestic poultry. This exhibition, for which active preparations had been some time in progress, took place on Wednesday, December the 1st; and, whatever the previous anxiety of those who had been most interested in the success of the undertaking, the subsequent comments of all whom it brought together are sufficient evidence that they did not overrate the interest and attention that it was likely to awaken in the district assigned to its operations. It was, indeed, natural that many would doubt the probability of such general support as more sanguine individuals ventured to anticipate, but it cannot be otherwise than satisfactory to feel that such doubts have been thus overcome, and that some of those who thought least favourably of the project have given the most decided marks of approbation at a triumph so little expected. Everything, indeed, concurred to stamp success on this first meeting of the Winchester and Southern Counties' Poultry Show; the continuous rain of the last six weeks had at length ceased, and a bright sunny day both favoured the travels of the feathered competitors, and aided the necessary preparations for their reception, which took place on Tuesday, and on the evening of that day all were ready for the inspection of the next morning.

The Rotunda of the Market-House, and two large rooms, contained 172 pens, on which we purpose to make some few remarks, in the order they occupied in the Catalogue and the Judge's Award. The latter individual appears to have thought but lightly of Hampshire Bantams as there represented, for although a first prize was awarded to the Gold-laced birds, that was assigned to the pen belonging to Capt. Hornby, R.N., of Knowsley, in Lancashire, and certainly, in colour, figure, and condition, we yield a ready assent to the verdict. A second prize was assigned to this class; and the Partridge Bantams of Mr. Sayers were deservedly admired. The Silver-laced and White Bantams were but indifferent, and the Black ones had no representatives. It may not be amiss to remind our readers, that however desirable size and an upright comb may be in a Shanghae, they are all equally so in the present instance.

Near neighbours were the tiny winners in this class to Mr. Sturgeon's magnificent pen of Shanghaes, which bore off no less than three different prizes, viz., that for the best cock and two hens, with the separate awards for the best single cock, and the same for one of the hens. Weight, colour, condition, and figure, were here displayed in full perfection, and were there room to add another laurel to their owner's wreath, every voice would have at once accorded it; they were pre-eminent, and fortunate would it have been for the Judge if no greater difficulties had come before him than could have arisen from any comparison of these with their competitors. Mr. Sayers' birds, and those belonging to Mr. Gilbert, were good specimens, and could have no discredit reflected on them by suffering defeat from such antagonists.

In Class 3, for a Cockerel and three Pullets of 1852, Mr. Sturgeon's name again appears with all the honours. This class contained twenty-seven entries, of which No. 41 belonged to Mr. Punchard, of Blunt's Hall, Haverhill, Suffolk; the Cockerel was a bird of remarkable beauty in point of

make and colour, the latter a rich buff, powdered, as it were, with orange, gold hackle, and singularly free from any dark feathering; the pullets were equally meritorious as regarded plumage, no less than distinctness of form.

Another year we shall, doubtless, have to chronicle a more even class than were exhibited on this present occasion; birds will then be better matched, and sent in higher condition; but while we venture on this anticipation, let us at the same time acknowledge sincere thanks to all those who were willing to send birds to give *eclat* to this first exhibition, and to encounter criticism rather than run the hazard of empty pens.

In Class 6, a cock and two hens of Mr. Punchard's had a first prize; and, though alone in their class, it would assuredly have been very difficult to have seen adjoining pens equally well-filled. While prevailing taste, as we admit, induces us to regard with longing eyes the lighter-coloured varieties, we frankly admit that the robust character, well-proportioned figure, and delicate markings of such birds as occupied pen 35, will always have great attractions in our eyes.

The class for Chickens of the Brown and Partridge was indifferent; and several points, both as to figure and colour, should have due consideration before another year again sees the Market-house similarly occupied. The possession of five toes will not enable them to perch more readily, or facilitate their movements on the ground. A good pair of white Shanghaes were shown, as single specimens, by Mr. Sayers; and a pen of Chickens of the race came from Mr. Chase, of Turwick. Many of the Shanghaes, competing as single fowls, were exhibited in the Rotunda; while the majority of this class occupied the large room on the left of the entrance; a position, during the whole day, so densely crowded, as clearly to indicate the greatest point of attraction. The single-combed Speckled Dorkings were present in great force and excellence. We concur, however, with the award that gave the first prize to Mr. James Lewry; in whose pen, colour, figure, and substance, were also admirably represented. Lady M. Macdonald had good birds exhibited in this Class; and her Ladyship was also successful in Class 19, where rose-combed birds of the same race competed. Captain Hornby's Cockerels and Pullets in this class stood alone. Mrs. Mills' White Dorkings were shown in excellent condition; and, in shape and substance, left little to be desired; we could have wished, however, that the bill should have been quite free from any dark markings. Their competitors were without blame in this respect, but yielded the palm in respect of figure and condition, in which the winners were pre-eminently distinguished. Game fowls occupied but two pens; of which No. 98 contained well shaped birds; but we could not but regret the absence of other specimens of one of the most beautiful varieties of our domestic poultry.

Golden Hamburgs, both Pencilled and Spangled, were absent from the list. Another year we trust to see this omission supplied; for few members of the gallinaceous tribe will better reward our labours, where external appearance is mainly regarded. But brilliantly were the fortunes of the family retrieved by their first-cousins the Silvers, which, in both the Spangled and Pencilled varieties, were evidently anxious to atone for their relations' absence. Mrs. Mills' Pencilled and Mr. Chambers' Spangled birds were almost safe from criticism, if such an assertion can ever be safely made. The second prize for the Spangled birds was assigned to the pen that took the first prize at Lewes in the present year.

The Malays were but few in number, and, although good specimens were shown by Mr. Sayers, we cannot but hold to our opinion, that in all points they are at least equalled, if not exceeded, by their Oriental neighbours, the Shanghae.

Class 62 presented three very good pens of White Crested Polands—birds that deserved commendation no less for their general figure than for the great beauty of their tufts, which, especially in the winners, were perfectly globular and even. The prize for the best cock fell to the bird in the pen that took the second prize in Class 62. The extreme regularity of his crest, and points of excellence in figure generally, justly gave him precedence, although the fair sex were better represented in the younger birds.

Were it not that we hope to see all classes satisfactorily

represented when another year has passed over us, the Polish family should no longer occupy one pen; but since the Winchester, in common with all other Societies, seeks to improve, we may express our hope that the Golden and Silver-spangled Poland, whether ruffed or otherwise, will then come before us in a more favourable light than that in which we can now venture to regard them.

In Spanish, Captain Hornby met with his usual, but well deserved success; and many a claimant was at hand for the purchase of these much-coveted favourites.

Pigeons were few in number; but a pair of Capuchins and another of Carriers, belonging to Dr. Wesley, of Winchester, were justly distinguished. The Tumblers were fine birds.

In Ducks, Lady M. Macdonald had a pen of East Indian (the Labrador is as entirely a misnomer for these birds, as the term Cochin-China is for Shanghae's). A first prize was awarded for this pen, there being no other competitors; but we should wish to see a fuller display of the golden-green metallic lustre on both ducks and drake.

The Aylesbury Ducks of Mr. Edwards, Captain Hornby, and Mr. Page, fully merited the Judge's award. Mr. Edwards' other pen of older birds were probably passed over on account of their stained bills, a change we were informed that was first perceived at their last moulting. Of Mr. Punchard's Rouen Ducks, our commendation must be strongly expressed—they were excellent in every respect.

We cannot think that Hampshire, or any of the southern counties were at all fitly represented by the Geese that came into competition on this occasion; and its farmers will do well to look to the Toulouse Goose, either pure or crossed with our own breed, to give both size and quality.

Lady M. Macdonald was successful with her Turkeys, of which some bronze-tinted birds carried off the first prize; but this class also will admit of improvement.

No. 168 contained a pair of Guinea Fowls in good plumage.

This ends the Catalogue of the First Winchester Show; and if in its subsequent progress it retains its claim to that public support which has been so liberally, yet so justly awarded to its infancy, the expectations of those who first suggested its establishment will be fully realized, and amply rewarded.

The verdict of Birmingham Judges was at one time the sole authority to which English poultry-keepers had to direct their attention, but now, from Penzance to Yarmouth, and the most northern counties, an eagerness for information is being manifested in these matters, which can only be accounted for on the ground of such details being at length recognized as a profitable branch of farm economy. If poultry exhibitions should prove the means of directing general public attention to this branch of the farmer's revenue, while others are represented in so unsatisfactory a state, the object of their promoters will be fully attained. These Societies have directed their labours, in the first place, to what may prove profitable to the farmer and cottager; and, if in so doing, they can render service to any other class, by gratifying individual taste or inclinations, they will thus gain an additional motive for increased exertions. The multiplication of these Institutions will certainly have one beneficial effect, which we hope, indeed, is already recognized; we allude to the comparison which the exhibitions of adjoining districts must inevitably suggest, and the consequent more definite classifications of those principles on which awards are to be assigned. If the former fact may possibly instigate more minute inquiries into the reasons and authority for such decisions, and thus add to official responsibility, the latter will fully atone for such judicious hazards, by the gradual substitution of a more generally recognized standard of excellence and merit.

The Judge on the present occasion was the Rev. W. Wingfield; and we never knew decisions more generally approved. We will conclude with a List of the Prizes he awarded.

Class 1.—BANTAMS.

5. First Prize—Cock and two Hens, golden-laced, 5½ months old, £12 12s. Captain Hornby, R.N., Knowsley Cottage, Prescott, Lancashire.
9. Cock and two Hens (partridge), one year old, £3—A. C. Sayers, Esq., Clanville House, Andover.
3. Second Prize—Cock and two Hens, gold-laced, three years old—H. Holloway, Esq., Marchwood.
12. Highly commended—Cock and two Hens, gold-laced, 18 months, £2—Mrs. Mills, Bisterne, Ringwood, Hants.

Class 2.—COCHIN-CHINA (Cinnamon and Buff).

- 13. First Prize—Cock and two Hens—Thos. Sturgeon, Esq., Manor House, Grays, Essex; and prize for best Cock and best Hen.
- 16. Second Prize—Cock and two Hens, hatched 3rd of March—A. C. Sayers, Esq., Clanville House, Andover.
- 17. Highly commended—Cock and two Hens, eight months old—A. Gilbert, Esq., 17, Upper Phillimore-street, Kensington.
- 21. Cock and two Hens, Cock 18 months—Mr. H. Higgs, Southampton.

Class 3.—COCHIN-CHINA (Cinnamon and Buff).

- 29. First Prize—Cockerel and three Pullets, hatched in March—Thomas Sturgeon, Esq., Manor House, Grays, Essex.
- 41. Highly commended—Cockerel and three Pullets, eight months—C. Punchard, Esq., Blunt's Hall, Haverhill, Suffolk.
- 32. Commended—Cockerel and three Pullets, hatched last week in March—Mr. Wheeler, Commercial Road, Southampton.

Class 4.—COCHIN-CHINA (Cinnamon and Buff).

- 47. Commended—Single Cock, 10th March—Mr. R. Griggs, Marchwood.

Class 6.—COCHIN-CHINA (Brown and Partridge).

- 55. First Prize—Cock and two Hens, chickens of 1851—C. Punchard, Esq., and prize for best Cock and Hen.

Class 11.—COCHIN-CHINA (White).

- 72. First Prize—Cockerel and three Pullets, hatched 29th of May, £35—G. Chase, Esq., Turwick, Petersfield.

Class 12.—COCHIN-CHINA (White).

- 73. Prize—Single Cock, one year—A. C. Sayers, Esq., Andover.

Class 13.—COCHIN-CHINA (White).

- 74. Prize—Single Hen, hatched 23rd of April—A. C. Sayers, Esq.

Class 14.—DORKING (Single-combed).

- 77. First Prize—Cock and two Hens, 14 months, £5—Mr. James Lewry, Handcross, Crawley, Sussex; and prize for best Cock and Hen.
- 76. Second Prize—Cock and two Hens, old—Lady M. Macdonald, Woolmer, Liphook, Hants.

Class 15.—DORKING (Single-combed).

- 83. First Prize—Cockerel and three Pullets, five months one week, £4 4s.—Capt. W. Hornby, Knowsley Cottage, Prescot, Lancashire.
- 81. Highly commended—Cockerel and three Pullets, five months and one week, £4—Mr. James Lewry.

Class 16.—DORKING (Single-combed).

- 84. Commended—Single Cock, two years old—H. Holloway, Esq., Marchwood.

Class 18.—DORKING (Double or Rose-combed).

- 86. Second Prize—Cock and two Hens, old, £10 10s.—Lady M. Macdonald, Woolmer, Liphook, Hants.

Class 19.—DORKING (Double or Rose-combed).

- 89. First Prize—Cockerel and three Pullets, five months two weeks, £4.—Mr. James Lewry, Handcross, Crawley, Sussex.

Class 22.—DORKING (White).

- 91. First Prize—Cock and two Hens, fifteen months, £3.—Mrs. Mills, Bisterne, Ringwood, Hants; and prize for best Cock and best Hen.

Class 23.—DORKING (White).

- 94. First Prize—Cockerel and three Pullets, six months, £2 10s.—Mrs. Mills, Bisterne, Ringwood.

Class 25.—DORKING (White).

- 95. Commended—Single Hen—N. Antill, Esq., Portsea.

Class 38.—GAME (Duck-wing and other Greys and Blues).

- 98. First Prize—Cock and two Hens, 20 months, £2—G. E. Lowman, Esq., Lyndhurst; and prize for Cock and best Hen.
- 97. Second Prize—Ditto, 20 months, £2 10s.—Same.

Class 50.—SILVER-PENCILLED HAMBURGH.

- 100. First Prize—Cock and two Hens, 18 months—Mrs. Mills, Bisterne; and prize for best Cock and best Hen.
- 101. Second Prize—Cock and two Hens, three years, £1 1s.—W. G. Chambers, Esq., Portsmouth.

Class 51.—SILVER-PENCILLED HAMBURGH.

- 102. First Prize—Cockerel and three Pullets—W. G. Chambers, Esq.

Class 54.—SILVER-SPANGLED HAMBURGH.

- 103. First Prize—Cock and two Hens, Cock and one Hen three years, and one Hen 1852—W. G. Chambers, Esq.; and prize for best Cock and best Hen.
- 105. Second Prize—Cock and two Hens, 15 months—Mrs. Mills.

Class 58.—MALAY.

- 109. First Prize—Cock and two Hens, two years—A. C. Sayers, Esq., Clanville House, Andover; and prize for best Cock and best Hen.

Class 59.—MALAY.

- 110. First Prize—Cockerel and three Pullets, hatched in May—C. Rawson, Esq., the Hurst, Walton-on-Thames.

Class 62.—POLAND (Black with White Crests).

- 112. Second Prize—Cock and two Hens, two years, £10—Mr. T. P. Edwards, Lyndhurst Railway Station; and prize for best Cock.
- 113. Cock and two Hens, seven months, £10—Same; and prize for best Hen.
- 111. Highly commended—Cock and two Hens, 16 months, £3 10s.—Mrs. Mills.

Class 63.—POLAND (Black with White Crests).

- 114. First Prize—Cockerel and three Pullets, five months, £5—Mr. T. P. Edwards.

Class 82.—SPANISH.

- First Prize—Cock and two Hens, 18 months, £4 4s.—Captain W. Hornby, R.N., Prescott, Lancashire; and prize for best Cock and Hen.
- Second Prize—Cock and two Hens, 18 months—Mrs. Mills.

Class 83.—SPANISH.

- 125. First Prize—Cockerel and three Pullets, five months and eight days. £8 ss.—Captain Hornby.

Class 87.—PIGEONS.

- First Prize—For Capuchins, Tumblers, and Carriers—Dr. Wesley, Winchester.

Class 88.—DUCKS.

- First Prize—Drake and two Ducks (Aylesbury), two years—Mr. T. P. Edwards, Lyndhurst Railway Station.

- 157. First Prize—Drake and two Ducks (Rouen), eight months, £3.—C. Punchard, Esq., Blunt's Hall, Haverhill, Suffolk; and highly commended (Rouen), full age, £3.
- Second Prize—Drake and two Ducks (Aylesbury)—Captain W. Hornby, R.N., Prescot, Lancashire, 5½ months, £1 12s.

- 154. Commended—Aylesbury—Mr. W. B. Page, Hill, Southampton.

Class 89.—GEESE.

- 162. First Prize—Gander and two Geese, 1851—G. Bridger, Esq., Chilcombe.

Class 90.—GUINEA FOWL.

- 168. First Prize—Pair of Guinea Fowls, 16 weeks—H. Holloway, Esq.

Class 91.—TURKEYS.

- 170. First Prize—Turkey Cock and two Hens, light-coloured, £6 6s.—Lady M. Macdonald, Liphook, Petersfield.
- 169. Second Prize—Turkey Cock and two Hens, Black Norfolk, £6 6s.—Lady M. Macdonald.

RAPID GROWTH OF SHANGHAI FOWLS.

In calculating the cost of feeding fowls, "Gallus" should certainly make a distinction between full-grown birds and chickens. While it is generally admitted that Cochinchina chickens eat more than others, that full-grown Cochins should eat less than others, will, perhaps, not be disputed, when it is remembered how large a portion of their time is passed in the brooding fit. From the comparative smallness of their eggs, they must eat much less than their rivals the Spanish; and from their natural inactivity, compared with the Dorkings and Spanish, they must require less nourishment.

With regard to those fearful eaters, Cochinchina chickens, it would be well to match them with others of exactly the same age, and to note the increase in weight of each bird. A friend of mine has a cockerel that has increased an ounce each day for some time, and now weighs 12 lbs. Pullets at a certain age increase an ounce each day until after they begin to lay; as they get to the end of the batch, they begin to decrease in weight; but below a certain age, the daily increase is less, on which account the chicks that are matched should be of the same age. I give a list of the increase in weight of seven of my Cochinchina pullets for ten days—

	Hatched.	Weight Nov. 3. lbs. ozs.	Increase.	Weighted Nov. 13. lbs. ozs.
1. May 15	6 2½	10½ 6 13
2. " 25	5 5	8½ 5 13½
3. " 25	5 2½	7½ 5 10
4. June 13	4 15	6½ 5 5½
5. " 13	4 13	5½ 5 2½
6. " 13	4 11½	6 5 1½
7. July 27	3 12½	4½ 4 1

During the above ten days my hens had become broody, and had lost each nearly one ounce per day. I have not been able to prove this time what they lose during a sitting.—W. P. BEEBY, *Chuldon, near Coulsdon, Surrey.*

BRITISH EATABLE FUNGI.

(Continued from page 169.)

Why should we despise what our continental neighbours not only use as a common food, but also consider a luxury? Is it because prejudice is one of the prevailing fashions of our land, which we feel in duty bound to follow; or is it because we have so long been ignorant of the British

edible fungi, that we consider we are now too old to be taught? No markets might be better supplied with such fungi than the English, in spring and autumn, and yet with the exception of the common mushroom, they are rarely exposed for public sale.

Out of at least thirty esculent species (including most of those eaten on the Continent) indigenous to our British isles, only two or three are commonly eaten, and this with agricultural distress and the poverty of the poor, while abundance of nutritious and wholesome food surrounds them on all sides and rots beneath their feet; food which on the Continent not only supplies the edible diet of thousands of the poorer classes, but also luxuries to the rich, which in this land both classes of society are deprived of, and Great Britain continues to be the only country in Europe in which this valuable food is wasted and despised.

Perhaps the undisturbed peace and prosperity of our land, which enables us to cultivate and obtain abundant supplies of the productions of other countries, induces us to believe that our own natural productions are almost unworthy of notice. The Chinese present a striking contrast to ourselves, in the attention paid to their esculent vegetation, having printed annually some thousand copies of a work describing those plants which are suitable for food, and distributing them gratuitously to the poor in those localities which are most exposed to natural calamities. Such an instance of provident solicitude on the part of the Chinese, for the lower classes, may be suggestive in our own land, and a more general knowledge of native plants useful in medicine, domestic economy, and the arts, would be an important and interesting branch of education.

With the exception of the common Mushroom and the Truffle, scarcely a single species is generally known; the Morell is so local and scarce that it seldom appears at table, and the greater portion sold are probably imported. The much esteemed *Cantharellus cibarius* is but little known, except to the Freemasons who keep the secret. I quite agree with Dr. Badham, when he states, that we should be rendering a better service if we applied ourselves to the task of discriminating the esculent from the poisonous fungi, rather than condemn them universally, because we cannot at a glance select the good from the bad, and will not pay that attention to them they so justly deserve, nor does it speak favourably of the superiority of the human race, and the proper employment of their faculties, when they allow the brute creation to surpass them in their diagnosis of food.

I shall now enumerate, separately, the esculent species of most importance, as mentioned by Dr. Badham, commencing with the *Agarics*; in doing this, I shall not pretend to give the discriminating characters, as I consider no one ought to commence collecting them for the table, without some previous botanical knowledge, or the assistance of some botanical friend, in which case, of course, they would possess themselves of some scientific work upon the subject. But should they not investigate the subject themselves, I should advise them not to check the progress of others labouring in the field, while their want of knowledge will not justify them in giving an opinion, as by so doing they may injure others, without themselves deriving any benefit.

Agaricus prunulus.—This fungus is highly esteemed, and much sought after, particularly as it occurs in spring only, when fungi generally are of rare occurrence; the borders of woods and pastures is the proper place to seek it. I have not found this fungus.

A. procerus.—This is a very handsome and delicate fungus, and by no means rare, growing plentifully late in the summer and autumn, on downs, &c. I have found it abundant in Hackwood Park, near Basingstoke; on the common near Odiham; at Hornsey, Middlesex; and on the banks of Loch ———, Ireland. This is a very agreeable, wholesome, and nutritious fungus in its raw state.

A. campestris.—Although most persons would feel indignant were they accused of not being able to select, without doubt, the common mushroom from its thousands of companions, it may be well to remark, that there are several varieties of the common mushroom, and that many of their despised, though equally valuable neighbours, might be recognised with equal facility, if the veil of prejudice which dims the vision was for a short time discarded.

A. exquisitus (Horse Mushroom).—This fungus is much

larger and coarser than the common mushroom, and when stewed I found it hard, and inferior in flavour; it is by many considered superior to the common mushroom for making ketchup, for which purpose it is brought into the markets for sale this autumn. I saw a basket in the Winchester market, and upon questioning the seller, she denied that they were horse-mushrooms, stating that she considered the latter poisonous; from her description, I concluded that she considered *A. procerus* to be the horse-mushroom, which is known to be the most wholesome in its raw state, of any fungi. *A. exquisitus* grows abundant under trees, and in a young state is of a brilliant white, having a pleasing effect in the gloominess caused by our hanging trees. I have found it fine and abundant at Archer Lodge, near Basingstoke, and on the banks of Lough Neagh, Ireland. Abundant in autumn.

A. oreades.—This fungus, of course, is well known as the Champignon, but caution must be taken in collecting, as two poisonous species nearly allied are occasionally found in company with it, namely—*A. dryophilus*, and *A. semiglobatus*; it is of so common occurrence in autumn, forming the fairy-rings, that I consider it unnecessary to quote localities.

A. nebularis.—This *Agaric*, which is considered rare, I have found sparingly at Archer Lodge, beneath fir-trees, has a very agreeable flavour when toasted and seasoned with pepper, salt, and butter.

A. deliciosus.—This I have heard spoken very highly of by several who have used it as an article of diet, stating that it really is as its name implies, delicious; unfortunately I never found but three of this species at the locality last named, and, therefore, cannot speak from experience of its good qualities.

A. atramentarius and *A. comatus*.—These are so similar in appearance, occur so frequently in the same localities, and require the same treatment for the table, that I shall consider them together. I have found them both near Archer Lodge, and on the banks of Lough Neagh, Ireland. I have also found *A. comatus* in a lane near Winchester, and *A. atramentarius* beneath the willow-trees on the banks of the Basingstoke Canal.

A. orcellus.—This, which I consider the sweetest of all the *Agarics*, I found abundant in Hackwood Park, and Archer Lodge, growing beneath the shade of trees in considerable abundance.

The following esculent *Agarics* I have not yet found:—*A. heterophyllus*, *ostreatus*, *rubescens*, *melleus*, *ulmarius*, *fusipes*, *vaginatus*, *violaceus*, *castaneus*, *piperatus*, *virginicus*.

Lycoperdon plumbeum.—This fungus I have found in Hackwood Park; also, *L. bovista*, in Tangier Park, near Basingstoke. The *Tuber cibarium* (Truffle) is also abundant in the beach plantations about Hackwood; also, the *Helvella crispa* I have found in great abundance in the same locality. I have also found it in the plantations at Avington Park, near Winchester.

Boletus edulis and *scaber* I have found abundant and fine in the oak woods at Pamber, Hants; the *B. edulis* also in oak woods at Otterbourne, Hants, and Hornsey, Middlesex; and *B. scaber* very abundant under fir-trees at Archer Lodge.

Morchella esculenta.—I found one plant of this some years back, I regret to say before I knew its good qualities; it was looked upon as an object of considerable curiosity, and then cast away.

In conclusion, I will give a list of esculent fungi on which, as I have not found them, I cannot pass my opinion. *Amanita Casarea*, *Cantharellus cibarius*, *Clavaria coralloides*, *Fistulia hepatica*, *Hydnum repandum*, *Morchella semilibera*, *Peziza acetabula*, *Polyporus corymbosus*, and *frondosus*.

F. YORKE BROCAS.

THE DECOY-POND AND ITS WATER-FOWL.

A WALK of about two miles from my residence, over hilly heaths, brings me to a wild and solitary spot—a sort of deep valley, or glen. It appears as if a whole wood had been sunk into it until the tops of its loftiest trees were brought upon a level with the summits of the surrounding hills. Access can only be had to this sylvan retreat by applying to the keeper, an old Robinson Crusoe kind-of-man, who has

had charge of the place for the last twenty-two years, and who lives in a cottage close by. Furnished with an ignited piece of peat, that the birds may not, by scent, be made aware of any human approach, you enter through a rustic gate, overhung with foliage, and after winding your way for a short distance, amid gloom and underwood, emerge upon the edge of a beautiful expanse of water—a miniature lake, in which the shadows of the surrounding trees are reflected, and their branches dipping. A more lovely and sequestered scene can scarcely be conceived. Upon the water are wild-fowl, diving, sporting, or preening their feathers; these are the decoy-ducks, and this is the decoy-pond. A rivulet enters the glen at one end, and has been stopped up at the other; this occasions the water to overflow its banks and form into a basin; and the water can be raised or lowered at pleasure by means of the sluice-gate. But to render the pond complete for the purpose of taking wild or water-fowl (the terms are indifferently used), it is necessary to have an outlet at each of the four points of the compass, for the birds to pass up, as they will only enter that one down which the wind is blowing. The outlet or pipe, as it is called, is formed by making a cutting about eight or ten feet wide leading from the pond, and gradually diminishing in size as it curves to a point. It is crescent shaped, or resembles in form the blade of a common scythe. Over this arches are fixed, by means of hoops and upright stakes, leaving within the pipe, on each side, a bank of about two feet wide. The arches, or arch, for it is a continued series, tapering to the end, is covered with netting, and when finished exhibits a tube or tunnel. The earth which is dug out of the cutting is placed on the outer or convex side of the pipe, and forms a bank, behind which the decoy-man can pass without being noticed by the birds inside. Along the inner or concave side of the pipe, screens made of reeds are placed at an angle of about forty-five, inclining towards the pond, so that a person standing where these screens converge towards a point can see between them, and command a view of the whole length of the tunnel. There are five of these pipes in this decoy, and these, with a few minor appliances, and a rustic shed or two for holding baskets, tools, &c., complete the establishment.

Water-fowls are winter visitors, and usually begin to arrive in the first or second week of October, and leave at the end of March. Unlike other birds, they feed at night, and resort to the Decoy-pond for rest and security during the day. They are very timid and watchful; nevertheless, their vigilance is overmatched by human stratagem; and their place of safety becomes a trap. The birds principally caught in this pond are, Wild Ducks, Teal, and Widgeon. The Teal and Widgeon prefer deeper water, and frequent a pond near by. 5311 Wild Ducks, beside other fowl, was the number which the decoy-man informed me that he had taken in the last of what he called the good seasons, seven years ago; since which the birds have greatly decreased, and he seldom captures now more than one-third or one-fourth of that number. He attributes this falling off to the mildness of our winters, and the eggs, feathers, and flesh of the birds being more sought after in their native haunts.

Birds rise at dusk, that is, they leave the pond for their feeding places; and it is a beautiful sight to stand at a distance, at sun-set, and see hundreds of them emerge from the centre of the wood like steam of a cauldron; they return again at break of day in small flocks. For the first month after their arrival, the birds are allowed to pass to and fro, and remain in the pond undisturbed: during this time and a little before, the half-domesticated decoy-ducks, which have catered for themselves in the pond during the summer, are fed in and about the pipes, to induce them the more readily to enter them. In the morning, after noticing the direction of the wind, and lighting his piece of peat, the decoy-man proceeds cautiously to reconnoitre the pond, and, if all is favourable for his purpose, he commences the work of capturing: this is usually effected by tempting one of the decoy-ducks up one of the pipes by means of hemp-seed, small portions of which are thrown, from time to time, before them as they advance; the decoy-man, the meanwhile, being concealed behind the outer-bank, or inner-screens. The wild fowl accompany the decoy ducks, and when a sufficient number have entered the pipe, and passed far enough up it, the decoy-

man suddenly shews himself behind them, and the birds rush pell-mell to the smaller end, where they are taken off in a hoop-net, and killed upon the land. Should, however, the birds appear dull and inclined to sleep, recourse is had to the dog, not to drive, but to allure them. He is sent to the edge of the pond nearest to where the greatest number of birds are situated, suitable for working; he there snuffs about, and being regarded by the birds as an intruder, they rush towards him to drive him away—he knows his business, and leads on to the mouth of the pipe, which he enters, continuing along one of its banks, and, by a series of manœuvres, entices them onwards until they are secured and taken as before. Easy as it may seem to write about these birds, it is not so easy to catch them. Much skill, patience, and perseverance are needed; many disappointments are undergone, and exposure to wet, cold, and fatigue, and that for hours together, in the severest weather, have often to be endured by the decoy-man before he accomplishes his object.

The man, his dog, his cottage, and his haunts, have a wild look about them, and particularly the former when seen stealthily moving amid the dark shadows of the wood, with his fur cap on, and which is made to resemble an animal when he is peering over the top of a bank, or fence. In winter, the man is paid by the dozen for all the fowl he takes; and in summer, by the week, for repairing the nets and keeping the place in order.

Wild ducks are fond of frequenting creeks, bays, harbours, and tidal rivers; they hunt along the margins of them for eels, small fish, and crustaceæ; pick up the offal from vessels, and such as is brought down by the ebb-tide from towns. When the weather is mild and open they return to the decoy-ponds, well-fed, dull, and inactive, and are not so easily captured; but in severe weather, and during frosts, their supplies are diminished; fish lie deeper in the water, and crustaceæ deeper in the mud; shallow places are frozen, and the scarcity is often aggravated by an increase of birds. In this state of things they may often be seen upon the decoy pond, sitting on the ice by hundreds, and they are then more active, and are easier taken. The severest season, the richer is the decoy-man's harvest. It is not cold, but hunger which drives wild-fowl from their northern homes. Cold stops their supply of food, and sends it, at the same time, along our shores, whither the birds come in quest of it. In political economy supply follows demand: in the animal economy demand follows the supply; and it will probably be found that the migration of birds and fish are simultaneous, hunger being the motive power, and instinct the governing one. Water-fowl are an index to our fisheries; each species of birds has a predilection for a particular kind of fish; a knowledge of this, coupled with their presence in greater or lesser numbers, may enable us to form a comparative estimate of the state of our supply. What a wide and interesting field for study do the habits of these birds offer to the careful observer of nature who resides upon the sea-coast! They are living barometers, and prognosticate wind and rain, calm and tempest; in short, they are a beautiful link in the great chain of animal creation; they have a mission to execute, and they fulfil it with fidelity and precision; and does man, it may be asked, aided by the superior lights of reason and revelation, perform his part better?

S. P.—*Rushmere.*

THE DORKING FOWL.

WHAT IT WAS, IS, AND SHOULD BE.

I VERY much doubt if our Dorking fowls were ever a distinct breed. It is certain that very few birds bearing this name have much claim to purity. The Greeks and Romans tell of a famed five-toed breed; and so our Dorkings may have been originally derived from that source.

Some years ago, a breed of fowls thus named, bred at Dorking and in that neighbourhood, to supply the London markets, were much esteemed, as are now the large Surrey fowls, which still seem to command the best prices in those markets, as table fowls. Our old Dorkings were a rather small breed of fowls, colour white, sometimes with a few grey or cuckoo-dun feathers sparingly interspersed; they

had a full rose comb, short neck, wide shoulders, full chest, were wide across the hips, had short white legs, five toes, a broad tail, and though not remarkable for laying, were frequent and steady sitters; the chicken came early to maturity, and fattened easily; and were considered the best of all fowls for eating. In some few the hind toes were even triple.

Larger fowls being required for the markets, they were crossed with large sorts, and consequently lost many of their properties; such are the Surrey and Sussex fowls of the present day: of which a great assortment is to be found. These are known by various names, but are generally called Dorkings; of which breed some have one property, some another; some of them are double combed, and others single; short or long legged, four or five toed, being of no particular stamp or breed, and little better than a set of mongrels: their only recommendation is, that they are easily obtained, and, being good eating, are readily disposed of (at a price). Fowls of this nondescript variety of Dorkings are very plentiful in Kent, Surrey, and Sussex, and are considered good by some.

To these some persons are adding a dash of China blood; but they will still bear the name of Dorking fowls.

The improved Dorking should possess all the points of the old bird, with increased weight. Such fowls are very scarce: they appear very square-made birds, and in looking down on them seem almost as broad as long. They should have a large rose comb, short thick neck, short white legs, with five toes; altogether a rather lumpish-looking fowl.

In colour, the cocks are generally of a whitish-brown above, with a black or mottled breast, and black tail; somewhat approaching to the colour of a game cock called a Duckwing. The hens are grey, with light hackle, and sometimes slightly speckled with white. I do not, however, consider the colour of the feathers of much importance if the other properties are strictly adhered to; in which case, I think a good Dorking fowl will be found to have less offal than any other in proportion to its weight. The cocks often weigh 7 lbs., and the hens from 5 lbs. to 6 lbs., and some even more.

I fancy the Dorkings are more subject to Roup than are other varieties; as also to diseases of the feet; and that they lose their productiveness earlier than many varieties. But I am of the opinion, that if breeders would pay more attention to the properties of those birds they keep for stock, always selecting the best shaped and healthiest fowls, and never allowing them to breed in-and-in (that is, not to let too near relations breed together), but continually introduce fresh blood, being careful to select fine birds of the same variety for that purpose, they will soon find their stock improve, as well in health and beauty as in profitableness.

Bessel's Green, near Sevenoaks.

B. P. BRENT.

THE MUSK DUCK.

At a time when we meet with so many well-written articles in your columns upon the relative qualities of the different breeds of fowls, it may not be out of place to notice those of any other species of poultry. It is the Musk Duck that I would draw attention to. I have kept them four years, having purchased a fresh-imported pair direct from South America. I find them great layers, good breeders, producing two, and often three broods in the season. The eggs are mild and well-flavoured; the flesh delicious. The drakes will, if well fed, obtain the weight of seven pounds and upwards at three months old. As a proof how prolific they are, I have had, the last two seasons, broods from ducks hatched early in the spring. I have now a brood of six, five weeks old, by a duck hatched in February last, doing well. One most desirable property is (like the Cochinchina fowls), nothing seems to hurt or put them out of the way, they are so very docile. A CONSTANT SUBSCRIBER.

MERITS OF DIFFERENT VARIETIES OF FOWLS.

We have received so many letters upon this subject, that we can do no more than select from the facts they contain, re-

jecting, without any favour, the mere expressions of opinion; for these coming from anonymous correspondents are not weighty authorities.

ENDURING QUALITY OF SHANGHAES.—*Gallina* says, "I can find a hen, imported some six or seven years ago, and not very young then apparently, that has produced this season chicks from her own eggs. As for food, good barley being at 3s. 6d. per bushel, it costs me far less than 3d. per week each, and they eat until satisfied."

EXPENSE OF SHANGHAES, &c.—*Gallus secundus, M. D.*, declares, "So clearly have I been convinced of the positive extravagance of these birds, that I have been reduced to the miserable expedient of a pun, by asserting it to be as expensive to keep a Cochinchina as to keep a coach in China! They are, indeed, veritable cormorants, and I may exclaim, with the judicious "Thomas," that two will eat as much as a pig. My experience is most unquestionably to the effect, that the Spanish are the best layers. They lay more frequently, and their eggs are larger, but they are not so good for the table as the Dorkings. The Cochinchinas are decidedly good layers, and their eggs are very rich, though small in comparison with the Spanish."

MANAGEMENT OF SHANGHAE FOWLS.—"It may be interesting to you to know that, with the exception of a few ducks, my stock consists entirely of Cochinchinas. I keep five hens and a cock, as breeding stock, having had them presented to me by a friend, who imported them last spring. I have bred several pullets this year, which promise to be better than the old birds; and my idea is, to keep them as stock for next year, and to procure a very good cock. I hope by doing so, to improve my breed; and, by selecting my best pullets annually, and changing my cock, to bring my stock, in the course of time, to something like perfection. Is this the course adopted by successful breeders? [Certainly.] In feeding my poultry, I adopt the plan of always having food in the troughs, which sometimes consists of brewer's grains mixed with meal, and sometimes of boiled potatoes and meal. In addition to this they are fed (by hand) three times a day, with as much wheat or oats as will satisfy them; and, since last spring, I have ascertained that the cost of keeping old and young has not averaged 1d. per week each: in fact, up to the 1st of September, the cost was only about 3/4d. per week each. This, of course, is exclusive of scraps from the kitchen; and I may add, that they have the run of half-an-acre of grass land. In selecting pullets as stock birds for next year, I have chosen all of a light buff colour, being convinced that they are not only the most handsome, but quite as hardy as the dark variety."—T. J. O.

COST OF KEEPING FOWLS.—S. states, "For the last fortnight my stock has consisted of fifteen Spanish Fowls, viz., a cock and two cockerels, three hens and nine pullets, the youngest hatched in the beginning of last April, and although they have had free access to barley at all times during the fortnight, they have not quite consumed two-and-three-quarter pecks, which, at present prices, cost in this part of the country about 2s. 3d. My fowls have the run of about twenty perches of land, part grass and the remainder gravel, and in addition to the barley there has been given them daily, part (another yard of fowls taking their share) of the refuse of the kitchen, which I should think was over-valued at one penny a day, but say 2s. 10d. for the cost of the food of fifteen fowls for two weeks, or a trifle over 1d. a week per head. I have kept poultry for some years, and have found, after repeated trials, that a quarter-of-a-pint of barley per day, for every full grown fowl, with a grass walk not exceeding a quarter-of-an-acre, is rather more than will be consumed."

NOTES ON BEES.

I HAD contemplated that the subject of my next offering of Notes on Bees to the pages of THE COTTAGE GARDENER should have been entitled "Spring management on the moors," as a sequel to my last. But the year is gliding on so rapidly, that perhaps a review of the last season, in reference especially to the bees themselves, is more in place at present, and soon we shall look prospectively to the work of the coming spring. From the accounts received from all parts of the kingdom, it is evident that the apiaries in the

north have been more highly favoured than the southern sisterhoods. Though the spring had been unusually dry, many hives in early situations were ready for swarming the beginning of June, about the usual time in ordinary seasons; then came three weeks of chilling rains, when those bee-keepers (I am sorry to say they are still numerous), who maintain that bees which cannot support themselves are not worth assisting, lost many of their stocks. In some hives the royal nymphs were destroyed (in common hives this symptom of distress cannot well be ascertained); drones and larvæ (a certain sign of starvation) were brought out; while in others, without any of these precursors, families 20,000 strong ceased to exist. At last, when fine weather came, in some apiaries those hives which had received timely assistance swarmed with a determination which it was impossible to check, and in others the design of swarming was entirely abandoned. It is often difficult to understand the operations of the bees, from the very numerous combinations and circumstances which affect them; in these opposite results I am inclined to think that in those families which had been prepared to swarm two or three weeks previously, the queen had at that time finished the *great laying*, constituting the swarms; in fact, a quantity of eggs had been probably wasted, and thus, on the return of fine weather, there was sufficient vacant space for the storing of honey, as well as the deposition of eggs, in which, as Dr. Bevan observes, there is usually a relaxation in July. On this point, I only speak as compared to the prior laying, the queen still produces them in considerable quantities, as may be seen by examining the combs a few days after the swarm has been established, when many square inches will be found occupied with brood. According to the statement of Huber, in which Dr. Dunbar coincides, the diameter of a worker's cell is two and two-fifth lines, thus one square inch comprises fifty cells, including both sides of the comb. Dr. Bevan gives the dimension as two and three-fifth lines, which I think will be found the most correct measurement, and still affording a wonderful proof of the economizing of space.

The letter of Mr. H. Taylor, for the perusal of which the readers of THE COTTAGE GARDENER are much indebted to Mr. Payne, suggests subjects of deep thought to the apiarian. On the comparative merits of old and young queens, I will beg to offer a few remarks. As far as I am able to judge, more from attentive observation than lengthened experience, I am led to the opinion that a young queen will be equally prolific from the day she begins to lay eggs, *provided* all contingencies are alike. However, it must be borne in mind, that a young queen, established at the same time, and with as strong a colony as an older queen, commences her sway under much less favourable circumstances. A week, a fortnight, or even longer, elapses before she commences to lay eggs; and those apiarians whose hives enable them to view the whole body of bees at once, cannot fail to have been struck with the rapid diminution of their numbers during the working season, when there are no young bees to replace those that are lost. Then, as in spring, poverty in numbers is the parent of poverty. I have seen a queen of two months old, from this cause, laying her eggs "to mere waste," and have counted as many as three and four in one cell, while others were dropped and devoured by the workers. With profound respect for royalty, I admit having detected a queen condescending to deception. I found one of my young queens, this year, going through the routine of depositing eggs, examining the cells first, as is their wont; having reason to doubt this fact, I took out the window, and, making a minute inspection of the cells, found there was not a single egg. Next day she began to lay in earnest, but in another comb, and within a fortnight honey was stored in the cells where she had been *shamming*. But this is a digression, and I return to find further proof in favour of young queens. We have it on such good authority as that of Mr. Golding, that she has been known to lead off a swarm a few weeks after her birth. The second season in one summer enjoyed by bees near the moors, offers a full test of her powers. There we find stocks depopulated by swarming, and second swarms labouring under the disadvantages above-mentioned, returning to their owners with as large a population as their elders possess.

For instance, this season a second swarm filled a Grecian hive, and stored six or eight pounds of honey in a glass; while of four hives sent together to the moors, three of which were swarms, and one a stock which had swarmed twice, the stock came home decidedly strongest, so full, indeed, of bees, that had the season been May instead of the end of October, I should have looked for a swarm in a few days. Yet I do not imagine a queen deteriorates before her third year at soonest; and I am glad to see so experienced an apiarian as Mr. Taylor, is of this opinion, as well as Mr. Golding, whose "old lady," at four years of age, swarmed when she was dead!

This letter is already so long, that the consideration of queenless stocks and drone-laying bees must be deferred to another opportunity, if my pen should be again employed in transcribing from notes on bees.—INVESTIGATOR.

TO CORRESPONDENTS.

WEIGELA ROSEA (N. B. E.).—Surely you must know that the rose and the vine flower on wood made the same season; or, in gardener's language, on the current year's growth. The difficulty lies in this, that both the vine and the rose have been, or may be, pruned as close as to the last eye of the young wood, and to any other eye from the last to the one at the end of ten, twelve, or fourteen feet; therefore, they are not very good examples to teach the pruning of other plants from. It is a rule that ought not to be slightly broken, that all plants, when removed from one place to another, or transplanted, should be pruned in some way or other. Roses, low plants, and shrubs, like your beautiful Weigela, should be cut down to within a few eyes of the young wood; and stronger things, as large trees, only to be thinned of shoots, or cut according to the extent, the vigour, or the mutilation of the roots in the removal. But cases do occur, and yours is one of them, where it goes against the grain to fulfil the laws of pruning to the letter. For fear of misleading others, we must state your case before we advise you, however. You planted your Weigela this autumn, and it has from fifteen to twenty shoots rising directly from the crown or collar of the plant, their average height being three feet. This tells a tale. This plant was too large for the space for it, or else it was too straggling, and they cut it down to the ground to renew it. The shoots are now too numerous for a plant not transplanted; and one that has been lately removed must have about one-half of these shoots—the weakest ones—cut in from three to six inches in length; then take *three* of the strongest shoots, not cut, in your left hand, and cut off five or six inches from the points—then let them go; now, with your eye, measure the *best distances* between the top cuts and the bottom cuts, for cutting back the remainder of the shoots at different distances. Give the plant a good watering in April, three in May, and four in June—three or four gallons each time—and let us hear next August how it looks, &c., &c. In another year you will cut out all the very weak shoots and as much of the older wood as will keep the head regular, and the young shoots you will cut back, some to one-half their length, and some to one-third.

SHADED BORDER (R. A.).—What will grow on a five-foot-wide-border sloping a little to the north-west, and shaded with high laurels that may be cut down considerably? This question admits of many answers, yet none of them might be to your liking. Tell us what you would like there.

PRUNING STANDARD CHINA ROSES (A. J. F.).—It is not easy to answer about the pruning of monthly China Roses that are now straggling. The smallest Roses known are among the monthly Roses, and the very strongest also, as *Indica major*, and every degree of strength between these extreme points are also found in monthlies. Now, we all know that these, and every other Rose, will get straggling in time, unless they are attended to; but about the pruning of monthlies, without knowing what kind of monthly they are, is more than is safe to undertake honestly, without writing an essay to include all the possible shades of pruning. In a general way, very strong Roses must not be pruned at all on standards; that is to say, not much shortened; whole shoots cut out entirely, to leave more room for others, is the rule; standards, not very strong, may be pruned according to the degree of strength, without reference to what section they may belong to; and weak-growing standards must be pruned close, under any circumstances.

TROPÆOLUM TRICOLORUM (Michel).—There is nothing unusual in your plant starting vigorously and making as yet few leaves. You will have plenty by-and-by; the symptoms are *quite promising*. Do not give too much water in this dull weather. Let the pots be filled with roots before you soak the soil freely.

PLEROMA ELEGANS (Ibid).—How and when to propagate? In early spring, take off the points of half-ripened shoots; or, better still, select some shrubby side-shoots from two to three inches long; cut them across at a joint, and remove one or two tiers of the lower leaves; then plant them firmly in silver-sand, over sandy-peat, well-drained; water; allow to drain, and the tops to dry; then place over them a bell-glass, and plunge the pot in a sweet, mild, bottom-heat. After a few days, lift the corner of the glass at night, to prevent damping and to admit fresh air, and replace the glass firmly again in the morning, shading as much during the day as will prevent the shoots flagging, and no more.

WATSONIA FULGIDA (Troublesome).—This growing in the border, may be left there with the protection of a hand-light; but we think you would be better pleased with the blooms if you lifted it carefully, potted it, and kept it in a cold pit during winter.

BIGNONIA RADICANS MAJOR (Ibid).—The pot of this has been cracked, and then inserted in a deep, rich border, but the plant has not grown more than twelve inches since May. Examine the roots; remove at least part, if not most of the pot; and trace out the roots with the hand, and give them a little sandy-loam and peat, or leaf mould, to ramify in at first, and you will, most likely, have growth *enough* next year.

T. B.'S MODE OF PROPAGATING AND PRESERVING VERBENAS (*Ibid.*).—This mode is at page 374 of our last volume. We cannot say whether T. B. possesses a mild climate or not. In any climate in this country his mode would answer well for propagating; and with care in protecting, especially with waterproofed material as overalls, we should see no great difficulty. We are, however, no advocates for hand-lights for such purposes. You might have a glazed frame, and each light would cost you little more than a glazed hand-light, while there would be no comparison of the available surface-soil. In a frame or pit they would keep nicely under such treatment, and involve less labour than under hand-lights. See what Mr. Fish says to-day.

ALLAMANDA IN POTS (*A. Bartleman*).—You speak of having large old plants, and ask when to start them? As soon as you like. Cut back the long shoots of this year's growth to from six to twelve inches of the previous year's wood, allowing the leaves to remain on the wood left. After that, just see that the soil is not dry, as it is desirable to swell the buds left. An average temperature, from 55° to 60° at night, will do. When the days lighten and lengthen, in February, or before, add 10° or 15° to the temperature, and syringe the stems as well as water the roots. When the young shoots are several inches in length, give what shifting the plant requires, using rich rough loam and a little peat, and a pot not less than twelve inches in diameter, and a trellis at least three-and-a-half feet in height by two-and-a-half in diameter. When freely growing, give manure-water liberally. Success depends upon the vigour of the young shoots, and their being well exposed to light. *Allamanda nerifolia* may be grown in a pot as a shrub; the others require a considerable amount of room, whether on a trellis or a rafter.

VARIOUS.—*Margaret*, living in North Wales, kept 260 plants last winter in five windows, including Verbenas, Petunias, &c.; but has no greenhouse. 1. *Lotus Jacobæus* is rather a bad thing to keep; you did right not to pot it. You should not have given it a very rich compost at this season as a top-dressing. Prune away all the decaying and withered parts, and give no more water than will just keep it from flagging; and if you preserve life it will thank you for all the labour next summer. 2. *Lily-like plants*.—We can hardly make out whether your plant is a Lily, a Calla, or an Arum; but in its present symptoms you had better let it die down, but not to be quite dry. Any darkish place free from frost will do. 3. Your *Fern-looking* plant keep rather dry for a few months, and then water it freely. It is hardly worth growing. 4. *Mimosas* that have lost their leaves.—Do not repot now; just keep them a little moist at the root, but they will want little water until the leaves break afresh in the spring. We fear they will be rather strong-growing for the window. Before they break they will not require much light. 5. *Astromerias* nearly dying down.—Give them no water. They may be kept anywhere, where shelter from frost and wet can be afforded them. If you intend to grow them in pots, fresh pot before growth commences. 6. *Tropæolum* on a trellis.—Do not interfere with the tuber until the foliage has withered, nor for a short time afterwards. You may then take it up, place the tubers in a small pot surrounded with earth, and give no water; but when the young shoots begin to move, pot in a similar pot to that the plant is now growing in. Any place in the room will do now; it must have all the light possible when growing. See another answer to a correspondent. 7. *Cactuses*.—Do not think of moving them to a dark place; give them what light you can. Give no water unless they shrivel much, but avoid the least frost. Your success is very creditable to you; your mode of giving air in winter by the top of the window is admirable, and knowing such results lightens labours that otherwise would not be easily borne.

NAMES OF PEARS (*G.*).—*Passé Colmar*. (*W. B. N.*).—So far as we can judge from the sketches sent, and taking it for granted that the fruit is at maturity now, we should say No. 1 is *Passé Colmar*, and No. 2 either *Calebasse*, or *Beurré Bosc*; but this, of course, is mere guess-work in absence of the fruit itself.

ORCHIDS (*A. M. S.*).—Such delicate flowers as you sent should always be put into a tin-box, and be packed amongst soft, damp moss; put between thick paper as yours were, they are sure to be crushed coming through the post-office. They were flattened, and the colour squeezed out completely. As far as we could judge, they are—No. 1. *Zygopetalum Mackayi*. No. 2. *Zygopetalum crinitum*. No. 3. *Marillaria picta*.

GLADIOLUS GANDAVENSIS (*Cuto*).—This should have been planted last month, but as the weather has been so dreadfully wet they may be planted now, or as soon as we have three consecutive fair days. Mr. Appleby is preparing lists of all the best florists' flowers, and will give the *Chrysanthemum* very soon. For its culture see the back numbers of *THE COTTAGE GARDENER*, or *The Cottage Gardeners' Dictionary*.

ZERO.—We have written to the gardener, and as soon as we receive his answer you shall know.

LAYERING CARNATIONS (*A Real Cottager*).—You do not say whether you grow your Carnations in pots, or in the open border. We suppose the latter. You may thin out the shoots, if numerous, and peg the remainder down the same as if you had layered them, only do not cut off the ends of the leaves. Lay a little good, rich earth over the bare shoots, and do not neglect to layer them next August, or they will most probably run their colours. It is a great pity you have not layered them, for even with the above care you will find them much injured in respect to the properties they would have had had they been layered at the right time.

VARIOUS (*C. C.*).—*Combretum Purpureum*. Plant this as you propose doing in the back border near the furnace. *Allamanda Schottii*, keep in a pot at the warmest end of the house; but we give you little hope of doing good with either, if your house is merely kept from being lower than 40° at night. Let it range from 50° to 55°, and you will find all will do well; but those heats would be too high for common greenhouse plants. The *Ipomæa* best next to *Learii* for a greenhouse, and not liable to spider, we think, is *Sellowii*. It will contrast with *Learii*, being a reddish-pink. But you must keep your eyes about you, as every *Ipomæa* is liable to spider if not duly watered and syringed. *Jasminum Sambac*. This you can only grow successfully in the temperature recommended above for *Allamanda*, though 5° less would do if not of long continuance; then give it a warm position. But if 40° to 45° be your average range at night, I would advise you to substitute *Jasminum gracile*, or *J. grandiflorum*, in its stead. The *Gracile* is a very short thing, that will do well either in a pot or against a pillar.

These two hints we would give you as a young beginner. 1st. Do not make a bugbear of insects. Every plant is subject to them if neglected. Care and attention will always keep them at a distance. We have seen people in a pretended agony about an insect-covered plant in a window; and yet five minutes use of their own fingers, and a drench from the rose of a water-pail, would not have left the vestige of a living thing upon leaves or stem. 2nd. Never go to the expense of getting large plants in pots like the *Combretum* sent to you, until you have previously ascertained if such a plant will suit your circumstances. As you have got it, try it in the place indicated. Your warm position and full exposure to sun may do much.

POLAND versus HAMBURGHS OR DUTCH.—"In *THE COTTAGE GARDENER* for November 18th, I observe a correspondent complains, that I have endeavoured to overset a uniformity of nomenclature respecting the Dutch Every-day-layers. I beg to state that such is not my desire; I only oppose the application of the name of Hamburgs to them, as it is the only one by which the mongrel Poles are known; whereas, the Dutch Every-day-layers have many, and ought to be satisfied. A 'Fowl Fancier,' at page 134, of the same number, while speaking of the Shanghaes, says:—"It is a libel to call the gangling, half-Malay creatures, which are so common, by the aristocratic title of Shanghaes." Now, this is exactly my opinion about calling the Hamburgs Poles. And, however unpleasant it may be to those keeping them to be told, that the least appearance of comb shows impurity, it is nevertheless true. My wish is to have things called by their right names, and to save, if possible, the true Poles, ere they become extinct. It is no new scheme of mine; for if your correspondent will refer to Mr. Trotter's Prize Essay, as it stands in *The Royal Agricultural Journal*, he will find them noticed separately there, although he has altered it in the separate edition of the same. Mr. Dixon's description of the Poland fowl I do not consider taken from good birds; but Mr. Richardson's description of them is excellent; but in the later enlarged edition of his work, some friend has tried to make him fashionable too, by mixing together what he had separated. I have not read Mr. Bailey's book, but will do so. It has become too much the fashion to call all tufted fowls, Polands, and all five-clawed fowls Dorkings, which I consider greatly injures the purity of those varieties."—B. P. BRENT.

SUTTON IN SURREY (*W. E. J.*).—The soil of which you require information in Surrey, is a fair, thin, sandy-loam, resting on the chalk formation. It is well adapted to the cultivation of common fruits, vegetables, and flowers. In that county, not very far from the place you name, there are large fields devoted to the cultivation of Lavender, Peppermint, Chamomile, and other flowering plants—we allude to the adjoining parishes of Mitcham, Carshalton, &c. Water is there obtainable from either wells, springs, or rain. Let "W. E. J." remember that it is found that sufficient rain falls on every house in England to supply its inmates with water. As to the rest, consult any Croydon land-agent or auctioneer, such as Blake, or Fuller, or Stedall.

ERRATA.—At page 143, for *Azalea* read *Aralia*; at page 143, for *Tilsoe* read *Silsoe*.

MR. STURGEON'S SALE (*A Fancier of Cochins*).—Lot 101, the cockerel by Jerry for which £12 10s. were given, was bought by Mr. Hodgkinson, of Birmingham.

WORKING GARDENERS' SOCIETY (*A few Working Gardeners*).—Let us know what funds you have or can command.

BOOKS (*I-forget-my-Name*).—Buy Loudon's *Self Instructor for Young Gardeners*. You do not want any instructions for preserving botanical specimens. Put each between several sheets of blotting-paper, and press it moderately till dry.

DAMP (1001).—"Steam" is not generated in a cold pit, the damp condensed on its glass arises from the exterior cold causing the air within to deposit its moisture. You understand our directions quite correctly as to the application of the peat, &c.

REMOVING VINE BARK (*R. S. E.*).—What says "F.?" "Nature never gave Vines bark that should be taken off by the hand of man; it was given them for a wise purpose, and, therefore, should not be removed again." Now this is neither so philosophical, nor even so reverential, as appears at first blush. Suppose we can admit, with "F." that it was given for a wise purpose, and removed for one equally wise—where is "F.'s" philosophy? It so happens, that our gracious Creator has not tied our hands in the use of material things very tight, or we had not been permitted even to prune away branches! But "F." should distinguish between a live bark and a dead bark. In our plan we take no living organs from the tree: only one crime we commit—we take away a very good non-conductor of heat, one which even in its decay doubtless subserves a very useful end. A tree with coarse dead bark on will neither become so rapidly heated nor cooled as a bare and polished one. So far so good. But we "give a sprat to catch a herring." We can, *in-doors*, manage all about these conducting powers easier than we can manage mealy bugs, the concealed spores of destructive fungi, &c. And this, as we conceive, is a justification of the practice, which, however, is established beyond all cavil, by the best gardeners in the kingdom. Prune your *peach-trees* any time from now to the end of January; get them nailed also, providing you can hang canvass or boughs over them directly. Like the bees, they do not require to be awakened in mid-winter.

PRUNING PEACHES AND APRICOTS (*H. M. S.*).—Prune your Peaches, but rather leave your Apricots till the first week of February. You cannot well distinguish the blossom-eyes on the young wood, or even the spurs. Look at an answer to "R. S. E."

VINE BORDERS (*A Country Gentleman*).—If your Vines have been unluckily concreted on the surface of the border—a notion unworthy of the age—we say, pull it all off, and apply a compost, in a slight fermenting state, composed thus—fibrous, free loam, one-part; lime-fubbish, one-part; leaf-soil, one-part; and manure one-part; well-blended. If you are "well-drained below," and your texture of soil right, pray do not take them up.

METEOLOGY OF THE WEEK.—At Chiswick, from observations during the last twenty-five years, the average highest and lowest temperatures of these days are 45.2° and 35.2° respectively. The greatest heat, 58°, occurred on the 16th in 1849; and the lowest cold, 14°, on the 16th in 1848. During the period 92 days were fine, and on 83 rain fell.

BRITISH WILD FLOWERS.

POPPY-WORTS.—PAPAVERACEÆ.

CHARACTERS OF THE ORDER.—*Sepals*, two, deciduous. *Petals* below the ovary, either four, or some multiple of that number, inserted in a cross form. *Stamens* below the ovary, either eight, or some multiple of four, generally very numerous, inserted in four parcels, one of which adheres to the base of each petal; anthers two-celled, innate. *Ovarium* solitary; *style* short or none; *stigmata* alternate with the placentæ, two or many; in the latter case star-shaped upon the flat top of the ovarium. *Fruit* one-celled, either a long pod with two placentæ attached to its sides, or capsular with several placentæ. *Seeds* numerous. *Albumen* between flesh and oily. *Embryo* minute, straight, at the base of the albumen, with plano-convex cotyledons.

PAPAVER. POPPY.

GENERIC CHARACTER.—*Calyx* below the ovary, of two egg-shaped, concave, blunt, equal, deciduous leaves. *Petals* four, roundish, crumpled, spreading, large; narrowest at the base; two opposite ones smallest. *Stamens* very numerous, filaments hair-shaped, much shorter than the corolla. *Anthers* terminal, erect, somewhat stalked, oblong, blunt, compressed. *Germen* roundish or oblong, large. *Style* none. *Stigma* round-shield-like, radiated, downy, permanent. *Capsule* egg-shaped or oblong-reversed egg-shaped, leathery, large, of one cell, incompletely separated into a greater or less number of marginal cells, answering to the number of rays in the stigma, between which the capsule bursts by as many valvular openings, under the stigma, which is more or less elevated by the incomplete partitions. *Seeds* kidney-shaped, numerous, minute, dotted, attached to the partitions.

Section 1.—*Poppies with bristly capsules.*

PAPAVER ARGEMONE; Long-prickly-headed Poppy; Wind-rose; Long-headed bastard Wild Poppy.

Description.—It is an annual. *Leaves*, pinnate, and the pinnae opposite to each other, and deeply pinnatifid, the end pinna being three-cleft; upper side nearly smooth, nerves beneath, and the leaf-stalks rough with spreading hairs. *Stem* leafy, about a foot high; this and the flower-stalk clothed with hairs pointing upwards. *Calyx* hairy. *Petals* wedge-shaped, narrow, often jagged, pale coppery-scarlet, with a black spot at the base, a little distant from each other, and falling in a few hours after opening. *Germen* reversed-cone-shaped, with a stigma from four to six rayed. The germen becomes a capsule having as many cells as the stigma has rays. The capsule is purplish, ribbed, and covered, but most thickly at its upper part, with white bristles, which point upwards. *Stamens* about twenty, with purple filaments; the *anthers* suspended by a fine thread from the top of the filaments; *pollen* bluish. *Seeds* blackish.

It is sometimes found with double flowers, but *Papaver maritimum* of Withering is only a starved specimen of this species.

Places where found.—Corn-fields, especially where the soil is sandy or gravelly.

Time of flowering.—June and July.

History.—This plant is found not only in all parts of Europe but in the Levant; but though so common is frequently unnoticed, owing to the speedy dropping off of its petals. *Argemone* is the old Greek name for this plant, and so called because its juice was found to allay the inflammation of the eyes, known by the name of *Argema*. The bruised plant was also recommended to be put upon the black or blue marks caused by any violent blow.

PAPAVER HYBRIDUM: Bound prickly-headed Poppy. Bastard Wild Poppy.

Description.—It is an annual. *Root* small and tapering. *Leaves* doubly pinnatifid, the segments being numerous, narrow, nearly equal, slightly bending back, and each tipped with a bristle; the pinna at the end of the leaf three-cleft; upper side nearly smooth, but the nerves beneath covered with bristles pointing upwards. *Stem* from twelve to eighteen inches high, this, as well as the branches and footstalks, which are channeled, covered with similar bristles. *Calyx* oval, and slightly hairy. *Petals* small, dingy-scarlet, often violet at the base. *Stamens* with purple filaments, and bright blue anthers. *Stigma* from five to eight rayed, and rather raised above the capsule. *Capsule* furrowed lengthwise, and thickly clothed with tawny bristles, pointing upwards.

Places where found.—In sandy and chalky fields; rare.

Time of flowering.—July.

History.—Never was a specific name more misleading than *hybridum* applied to this Poppy, for it is a true and permanent species. Gerarde says, speaking of both the species—"These plants do grow in the corn-fields in Somersetshire, and by the hedges and highways as ye travel from London to Bath. Lobel found it growing in the next field unto a village in Kent, called Southfleet, myself being in his company, of purpose to discover some strange plants not hitherto written of." Its medicinal powers were considered by the old herbalists to be the same as those of the preceding. (*Lindley. Smith. Martyn. Gerarde.*)

MANY of our readers have heard or read of the difference of opinion which exists respecting the true origin of that anomalous production—the purple Laburnum, *Cytisus Adami*. Some believe it to be a cross-bred plant between the common Laburnum and the purple *Cytisus*, while others as firmly assert that it must be the result of artificial treatment, although the facts respecting the process have escaped notice. The question is, therefore, still at issue, no clue having hitherto been discovered to decide it either way. Mr. Adam, in whose nursery, near Vitry, in France, it was originated about the year 1825, believed it to have issued from a blind bud of the purple *Cytisus* inserted in the Laburnum as a stock in the common way, as related in the Annals of the Horticultural Society of Paris in 1830 by M. Poiteau. A deputation from the Society was sent, after Mr. Adam's death, to ascertain if the original plant was really a seedling or a budded plant. But the evidence of this deputation was contrary to that of Mr. Adam's, and in favour of the cross-seedling side of the question.

This gave currency to many wild and extravagant ideas on the continent as to the effect of hybridisation. The old notion, that mules can revert to one of their parents, was strongly urged by some, and this anomalous plant adduced as a strong evidence that mules could change in time to either of their parents. Even the exploded doctrine of superfecundation was revived to account for the origin of such a plant; and to the present time no satisfactory answer can be given as to how, or by what means, the plant first originated, and it is altogether different from those variations called "sports." Our own belief inclines strongly to the artificial mode through the blind bud, because, among other reasons, if it is really a cross-bred plant, it stands alone in its habits among the thousands that have been so produced. Both parents, very nearly in their original characters, are produced simultaneously with the mixture between them; and the seeds of the two parents, thus produced, will come true in their generation without any variation whatever.

These facts of themselves amount almost to a proof that the purple Laburnum is not a cross-bred plant, but had its origin in some way which we have not yet discovered. For these peculiarities are widely different from the effects of hybridising on plants, as far as we have yet discovered them. We have not yet arrived at any conclusion which would indicate a law or rule by which the reversion of a true cross-bred plant to one or either of its parents is provided for; and, after experimenting on this point for very many years, we cannot say that we ever forced a true cross to assume or re-produce either of its parents; and we believe the thing is an actual impossibility in the vegetable kingdom. It is true that many writers on this subject assert, that what they call a mule plant will in time revert to one of its parents; but no one who has dived much into the mysteries of hybridisation can countenance such a doctrine. All that our experiments on the subject have hitherto brought to light is our own total ignorance of any such law. We cannot even, with any degree of

confidence, foretell whether the offspring of any two plants will be fertile or sterile. The most dissimilar species in any genus, if they will cross at all, will be as likely to produce a fertile offspring as not, while two others, to all appearance the nearest in aspect and affinity, will be equally likely to have a sterile offspring. We make use of the words fertile and sterile to get rid of the confusion caused by the different meanings given to the term mule by different writers. Professor Lindley, in his "Theory of Horticulture," limits the use of the word mule to the offspring of two distinct species, whether fertile or not; while he makes "cross-breeding" to cover all the productions between distinct varieties; and if all writers had kept to these definitions we should be at no loss to comprehend their meaning; but Dr. Herbert, late Dean of Manchester, applied the terms hybrid, cross-bred, and mule, indiscriminately, and scouted the idea of placing any limits between species and permanent varieties; while other writers apply the word mule to any cross that is sterile, and writers on cross-breeding in the animal kingdom are just as far at sea in their opinions and terms. An actual impediment to a proper understanding of the language of hybridisation is thus placed in our path, which it would be useful to remove by discarding the word mule altogether, or at least from our popular literature.

On poor, light soil the colour of the flowers of the purple Laburnum is much affected by the nature of the previous season. After a hot, dry summer the flowers are almost all of that dingy colour peculiar to the first variation, for a "sport" it can hardly be called; and after a wet, cold summer the yellow flowers of the Laburnum are in excess. These variations are not so manifest when the tree is growing in rich moist soil till it attains its full size. If we could fathom the law which governs these variations, it might form a step towards the clearing of the mystery which hangs over the real origin of the plant.

Dr. Herbert suggested a very ingenious and probable hypothesis to account for the possible origin of this tree, which can easily be reconciled with the statement given by Mr. Adam, already referred to. Dr. Herbert believed that the shield of the purple *Cytisus* bud might be still alive after the bud itself was destroyed, and that this live portion might unite with the Laburnum stock in the absence of a bud, and that the new wood, or cellular matter, which formed over the wound, between the shield and the stock, might produce an incipient bud, in the absence of a leading bud; and if the new bud was from an intermixed matter formed by the two plants, it could hardly fail of partaking of the two natures—that is, of the Laburnum stock and the purple *Cytisus* bud, which, in reality, it does; and the question is, how are we to proceed in order to obtain similar productions between other allied plants, for we must still adhere to the fact that species can only mix by pollen, or by this kind of union, when they are nearly related to each other. If it is possible to force a bud from two wounds in union with each other, and partaking of the natures

of two different species thus brought together, there can be no doubt about our being able to push this process farther than can be done by means of strange pollen in the usual way; and we think it can be done, for we perfectly concur in Dr. Herbert's view of the question. The well-known fact, that the two natures in the purple Laburnum aspire to separate themselves from the union, and assume their original character, cannot be accounted for on any other principle.

The means which Dr. Herbert suggested for effecting intermediate forms were to bud in the usual way, and, when the union took place to kill the bud, and to prevent the edges from uniting by lacerating the bark till a quantity of cellular matter was formed, from which a bud might be expected to issue, if the growth of the tree was checked in other parts. It is impossible, however, to succeed simply by this process. The question involves the true origin of latent or incipient buds—a question that has never been satisfactorily answered by any one.

We asserted, many years since, in "The Gardeners' Magazine," that if you cut out the buds from a yearling shoot, leaving only the top bud to carry on the branch, the part of the branch thus disbudded was incapable of producing a latent bud afterwards by any kind of manipulation. This assertion was much disputed by some in private correspondence, when Dr. Herbert opened the question in reference to the origin of the purple Laburnum. A new set of experiments were, therefore, set on foot, to prove if Dr. Herbert's suggestion could or could not be effected; these experiments were begun in 1841, and carried on till the end of 1847. The most conclusive of these experiments we shall briefly relate, as the result is, probably, the only stumbling-block in the way of clearing up the mystery which hangs over the origin of the purple Laburnum.

Truncheons of the common Willow are proverbial for the ease with which they root and produce shoots from all parts of their surface when planted or stuck into the ground. The Willow was, therefore, fixed on as the most likely plant to produce incipient buds. In the spring of 1841, cuttings were made from the strongest Willow shoots that could be procured of the former year's growth. They were two feet long, and all the eyes or buds were carefully cut out, except the three top ones, and they were planted in the usual way in rich kitchen-garden soil. In 1843, when these had made two year's growth, some of them were cut below the growing branches, leaving only a bare stump. Now, we should naturally suppose that a Willow shoot of full three year's growth, and with abundance of roots, in good soil, would not refuse to shoot forth buds and twigs from all parts of the bark. Not so, however; for they died away inch by inch, roots and all, without ever offering to produce a single leaf. In 1844, another lot of the same batch were cut, and they died in the same way. After this, the bark of others was lacerated in all directions, to see if buds would issue from the new-formed wood over these wounds, but all to no purpose; and the last two were cut in the spring of

1847, when they were much stouter than a walking-stick, and they died also. Now, these Willow-shoots, although united to other Willows by inarching or budding, could hardly be capable of producing an union-bud—as we suppose the purple Cytisus and Laburnum to have done—seeing that they could not do so on their own roots; at any rate, the inference is rational enough, and can hardly be controverted. How then, it may be asked, can you suppose the shield of a bud of the purple Cytisus could be capable of taking a part with the Laburnum stock to produce the purple Laburnum? We answer—simply, by surmising that the said bud was taken from a *two* or *three-year-old shoot* of the purple Cytisus, which is not at all unlikely, seeing how thin the bark of a younger Cytisus shoot is. Another inference in favour of this view of the question is, that in France they have always been in the habit of leaving more of the young wood attached to the buds in their nursery operations than is generally done in England; and all of us know, that if a bud on a two or three-year-old shoot is destroyed, a quantity of incipient buds will immediately issue from the surrounding parts. The close-spurring of the Grape Vine is founded on a knowledge of this fact or principle. Therefore, we can see no reason why two shoots of mature age, to form incipient buds, may not be made to produce an union-bud, if the parts are at first properly arranged; and we think we can see why union-buds are not produced in our nurseries when the more natural bud fails, leaving the shield alive and in union with the stock. Our invariable practice is to take the buds from one-year-old shoots; and we have seen, by the experiment with the Willow, that if buds on one-year-old shoots are once destroyed, the shoots are not able to furnish others; besides, it may require more than a season or two to ripen the young wood over wounds sufficiently to produce buds; and leaving a portion of the young wood attached to the bud, may have something to do with the time required.

After weighing these considerations, we think the safest way to treat Dr. Herbert's hypothesis will be to inarch two shoots of closely-allied species, not less than three years old; to bring an eye of each shoot directly opposite in the inarched part, to prevent the wound healing over in the vicinity of the buds for the first season; and when the junction of the edges took the following year, to destroy the buds, or the shoots, which may have sprung from them, and to cut away some of the surface-bark from behind the buds, so that if incipient buds were formed at all, they must come from the sides next to the wounded parts; and if the irritation caused by keeping the wound from healing over has forced the young matter from the two shoots to run into each other, and finally to have formed one solid body, there can hardly be any doubt as to the issue of this experiment. Let it first be clearly ascertained that it is possible to produce an union-bud, and then there need be no limits to the application of the process.—D.

COVENT GARDEN.

FOLLOWING up our remarks on the subject which has occupied our attention for the last two or three weeks, we come now to the consideration of *the Pear*. And here we would observe, that there is even greater room for improvement in the selection of its varieties than is necessary in the Apple. Even in the oldest orchards composed of Apples we find many first-rate established varieties; but it is not so as regards the Pear; and the reason is because it is only of late years that we have been made acquainted with that new race of varieties, for which the world is indebted to the genius of Dr. Van Mons. However much our ancestors may have been disposed to extend the cultivation of this as a winter fruit, they could not, for it had not been brought to the same degree of perfection as the Apple, and thus it is that our markets are so badly supplied during the winter months with such a succession of first-rate Pears as they are with Apples. All the Pears which are brought to market in any quantity are of the earlier kinds, and it would amount to an impossibility for any one to go to Covent-garden market during this and the following months and procure this fruit in the same quantity as they could two or three months ago. But still they can do so with the Apple, and what we want, is that they should do so with the same facility with the Pear. While Apples are now being sold, and will continue for the next four or five months to be sold at per bushel, we have Pears offered at per dozen, and per half sieve. Surely, then, this is a subject worth engaging the attention of those who have even a small portion of ground which may be occupied by such a crop.

In the following selection, we have chosen those which may be regarded as peculiarly rich in flavour, and such as would always command the best price in the markets. The late varieties, particularly, would amply remunerate the grower for any outlay he may incur. As before, we shall take them in the order of their ripening, and as the great object with cultivators is to have their produce either very early, or very late, we have studied the two extremes.

1. *Doyenné d'été*.—The earliest Pear which is worth cultivating, but it is very little known in this country. It is not of a large size, being considerably smaller than the *White Doyenné*, but for a Pear which is ripe in July, it is of good size and excellent flavour, being in this latter respect not unlike the old *Jargonelle*.

2. *Citron des Carmes*.—This is an old-fashioned but excellent early summer Pear, and admirably adapted for orchard planting, the tree being a strong and vigorous grower, an early and abundant bearer, and succeeding well even in exposed situations. It ripens in the early part of August.

3. *Williams's Bon Chrétien*.—We have been doubtful whether or not we are doing right in recommending this, the most delightful of Pears, to the notice of our friends. It is a very uncertain bearer, and those who depend upon it for a crop will be subjected to very frequent disappointments. Still, however, as we have before re-

marked, we are only treating now on what may be called economical planting, and, therefore, we venture to include this excellent variety. Most people, now-a-days, know *Williams's Bon Chrétien*, but if there are any who do not, let them by all means procure a tree. The fruit ripens in August, and continues in use during the greater part of September.

4. *Beurré d'Amalis*.—This is a variety which for a few years past has been rather largely imported from the Continent, and has become so great a favourite in Covent-garden, that many of our largest growers have made considerable plantations of it. None know better than the London market-gardeners what to plant, and we can seldom be far wrong in treading closely at their heels. This is a splendid early autumn Pear, of very large size, handsome shape, and delicious flavour. It ripens in September.

5. *Dunmore*.—This is one of those delightful varieties raised by Mr. T. A. Knight. It is of large size, and of a particularly rich flavour. Every orchard and garden should have it. It ripens in September.

6. *Seckel*.—Of all the Pears we know at this season, we know of none to surpass or even to equal the little *Seckel*. It is originally from America, but it succeeds to perfection in this climate. It is remarkably rich in flavour, and when fully ripe seems as if charged with a powerfully aromatic sirupy juice. It ripens in October.

7. *Beurré de Capiaumont*.—This of late years has been very abundant in our markets, and has become deservedly popular. It is well adapted for orchard planting, being a most abundant bearer, and a beautiful, handsome, and excellent fruit. It ripens in October.

8. *Jersey Gratioli*.—This is a particularly fine Pear, and, if we are not mistaken, we spoke in very high terms of it in some of our early reports. By way of climax, we can only say, wherever there is a garden, there should this Pear be. It ripens in October.

9. *Marie Louise*.—There are none of the Belgian Pears which seem to have had such an extended cultivation as the *Marie Louise*. It is now as common in the markets, and on the fruit-stalls, as the old *Swan's Egg* used to be. It is a most delightful and valuable Pear. The tree is extremely hardy, and bears well. It ripens in October, and lasts till the end of November.

10. *Figue de Naples*.—This is a Pear of good size and of the finest quality. It is comparatively little known, but should always find a place in every collection. The flesh is very buttery, fine-grained, and melting, with a particularly rich, sugary, and aromatic flavour. The tree is a most abundant bearer. The fruit ripens in November.

11. *Passe Colmar*.—A most delicious Pear, and certainly one of the richest-flavoured we know when it is met with in perfection. Its flesh is very fine-grained, very juicy, buttery, melting, sugary and vinous, with a rich aromatic flavour. It ripens in November, and continues over December.

12. *Napoléon*.—Dr. Diel said of this Pear, that one may be said to drink, rather than eat it. Its flesh is tender, melting, and juicy, and very richly-flavoured. It

ripens in November, and continues in use during December.

We must now draw our observations to a close for this week, seeing our space for the market report is rapidly diminishing. But as we have not a great deal to communicate, there being few novelties presenting themselves, we must be content with merely making a general statement.

The prices of fruit continue firm, and rather on the rise. APPLES, for kitchen uses, are making as much as from 5s. to 7s. 6d., and 8s. per bushel. They consist chiefly of *Hanwell Souring*, *Winter Pearmain*, *Alfriston*, and a great quantity of nondescript varieties. Among the choice varieties, we observed *Newtown Pippins*, *Ribstons*, *Golden Pearmain*, *Court of Wick*, and *Downton Pippins*. We do not observe many of the common kinds of PEARS; but there are plenty of the finer sorts, such as *Ne Plus Meuris*, *Nelis d'Hiver*, *Passe Colmar*, *Glout Moreceau*, and *Beurée de Rance*. GRAPES are plentiful, the supply from abroad being rather large. These make from 1s. to 2s. per lb. Home-grown Grapes are also pretty plentiful, and make from 2s. 6d. to 5s., and 6s. per lb.

In Vegetables there is the usual abundant supply, and, generally speaking, a good demand. CABBAGES make from 6d. to 1s. per dozen. COLEWORTS, 1s. to 2s. per dozen bunches. CAULIFLOWERS of good quality, 1s. 6d. to 2s. 6d. per dozen. BRUSSELS SPROUTS, 1s. 6d. per half sieve. CARROTS, 2s. 6d. to 5s. per dozen bunches. TURNIPS, 1s. to 1s. 6d. per dozen bunches. ENDIVE, 1s. to 1s. 6d. per score. POTATOES maintain last week's prices, and are rather inclining upwards.

PLANTS AND FLOWERS.—The supply of EVERGREENS increases, and consists of *Lauristinus* full of bloom. *Chinese* and *Siberian Arbor Vitæ*, *Aucuba japonica*, *Tree Box*, *Red Cedars*, and *Common Laurels*. CUT FLOWERS are very plentiful, consisting of *Chrysanthemums*, *Scarlet Geraniums*, *Roses*, *Heliotropes*, *Chinese Primroses*, *Camellias*, *Cinerarias*, and *Fuchsias*.—H.

GOSSIP.

WE are informed, and we think upon good authority, that our observations relative to the *Great Metropolitan Poultry Show* are not justified by the facts. We lose no time, therefore, in stating what has just reached us, namely, that the Exhibition has been instituted by a few gentlemen, and that no gain is to be made of the refreshments. We have also heard that Mr. Gilbert, who was one of the prize takers at Great Yarmouth, is a chief promoter of this Exhibition, and his experience will insure that it is well managed. These explanations, however, do not touch the general principle we advocated, and still advocate, viz., that Poultry Shows should not be established for private gain, and, we think, Mr. Gilbert's own experience will induce him to join us in recommending the principal exhibitors to unite in signing a declaration, and publishing it in the public papers, that they will not exhibit at any place where their birds are required to be exhibited for more

than two days. We have received a very temperate letter on this subject, from "One of the Hitchin Committee," which we will reply to next week.

The continued *wet weather* throughout November, and down to the time when we are writing (Dec. 6th), has been too seriously felt to require in this column any general comment; but we refer to it for the purpose of stating facts demonstrative that the usual exclamations about never remembering such weather are more than usually well founded. At Chiswick, in the twenty-six years extending from 1826 to 1851, both inclusive, the average fall of rain during November has been 2.182 inches, whereas in the November just concluded 6.20 inches of rain fell, or but little less than treble the usual amount! The excess is very great, even if we take the November when most rain occurred in those twenty-six years—namely, that of 1842, for in that month no more than 4.47 inches fell.

Last month we ought to have expressed the genuine regret we felt at the loss science has sustained by the death of *Dr. Gideon Algernon Mantell*; and we take the more blame to ourselves for the omission, because with him has always been associated the memory of his brother, *Mr. Joshua Mantell*, our friend of early days, who cultivated his Dahlias with no small success, attended to the physical needs of his neighbours, and indulged his literary tastes by writing his *Essay on Floriculture*, and editing *Baxter's Agricultural Library*, whilst resident at Newick, near Lewes. He died in 1839, and now, on the 10th of November of the present year, his more distinguished brother has followed him.

"Dr. Mantell was a striking instance of a rise in life amidst great difficulties. He was born in the parish of St. John's sub Easter, at Lewes, where his father was a shoemaker in a small line of business, but of quick parts, and with a readiness of perception, and a strictness of integrity, which rendered him extremely useful to Mr. W. Cooper, the leader of the political party supporting the Whigs.

"Dr. Mantell has well described his father's virtues in some lines on a tablet erected to his memory in St. Michael's church in that town, reverently ending with the wish—

"Oh fain would he, who in these humble lays
Attempts a father's and a good man's praise,
Follow the bright example thou hast given,
And humbly trace thy footsteps up to heaven."

"The family consisted of four sons and two daughters, and it was with great frugality that the sons acquired their education. Dr. Mantell received his first instruction at a dame school in the same lane as his father's house, and here he was so great a favourite that on the old lady's death she left him her little all. From her he went to the school of Mr. Button, in the Cliffe, where a sound and practical commercial education was given by a gentleman whose political sentiments were so accordant with those of Mr. Mantell the father, that he was known to be on the Government black list. The grammar-school at which Evelyn had been educated was not at that time available for a child of Mr. Mantell's political opinions, the twelve boys on the foundation being nominated entirely by the feoffees. On leaving Mr. Button's school, the kindness of Mr. Cooper came to the aid of the young man, who had attracted the notice of his father's friends by the diligence with which he devoted himself to his studies, and by his quickness and general desire to advance himself in knowledge; and the consequence was that he was apprenticed to Mr. James Moore, a surgeon and apothecary of the old school, an amiable and accomplished man, and a bon vivant. Here, again, Gideon Mantell so far conciliated the good opinion of his master, that, after he had "walked the hospitals,"

and, what was then a novelty in country practice, become a licentiate of Apothecaries' Hall, he was taken into partnership with his former master, and commenced a practice in his native town, which he carried on until the year 1835. In the course of that practice he was eminently successful, especially in cases of midwifery, on which branch, and especially on the use of the *ergot of rye*, he contributed several articles to *The Lancet*, in addition to many articles on other branches of medicine. His professional rival was Mr. Thomas Hodson, who was the great friend of Sir Astley Cooper and Mr. Abernethy, whose skill as an operating surgeon was equalled by few, even among the London practitioners, and whose practice in midwifery was as successful as that of Dr. Mantell. Indeed, so great was the skill of both, that it is recorded in *Smith's Philosophy of Health* (p. 149), that in fifteen years, out of 2,410 cases of parturition in the Lewes district at this time, there were only two deaths; and so fixed upon the attention of the poor was this success, that when Dr. Mantell was elected a member of the Linnæan Society, the popular belief was that F.L.S. meant that he had been elected a fellow of the lying-in society, and, as an old lady emphatically added, 'the society never had a better fellow.' It was in the exercise of his profession, also, and with the assistance of his accomplished brother, the late Joshua Mantell, then in his dispensary, that Mr. Mantell saved the life of a woman condemned to death for the murder of her husband by arsenic; Dr. Mantell having distinctly proved that the tests used, and which were said to have shown the presence of this mineral poison, had entirely and chemically failed. This led to his publication, in 1827, of his 'Observations on the Medical Evidence necessary to prove the presence of Arsenic in the Human Body in cases of supposed poisoning by that mineral. Illustrated with cases.' By the exertion of great interest, and solicitation, in addition to these scientific efforts, the woman's pardon was procured, and she still lives in Burwash.

"At Mr. Button's school Dr. Mantell evinced a strong love for the study of natural history, and, upon commencing his practice at Lewes, he stole—for it could be called nothing else—some hours from the very arduous labours of a country profession to the investigation of the 'Organic remains of a Former World,' firstly in the chalk, and next in the Tilgate formations, which were comparatively new ground. He was greatly encouraged in this work by Mr. Davies Gilbert, and he was largely assisted by the zeal and knowledge of Mr. Stewart Warren Lee, who was his most intimate friend and companion in all his early discoveries. He was also a keen follower of antiquity, and he opened many of the tumuli near the town. In this pursuit he was encouraged by the Rev. Mr. Douglas, the author of *Nænia Britannica*, who was Vicar of Preston, near Brighton. Their results were published in the first volume of *Horsfield's History of Sussex*.

"For nine years he devoted himself to the prosecution of his researches into the chalk formation, and in the foundation of the collection now in the British Museum. In May, 1822, he published, by subscription, the result of his labours in the quarto volume, 'The Fossils of the South Downs, or Illustrations of the Geology of Sussex,' the engravings being executed by his wife, to whom he had been married after an attachment formed during his unremitting professional attention to her father, and whose artistic skill would have done credit to a professional engraver. The work was dedicated to a Mr. Davies Gilbert, through whose recommendation Mr. Mantell was elected a F.R.S. in the year 1825.

"In 1824 he contributed to *Horsfield's History of Lewes* 'The Natural History of the District;' and in December, 1826, he published his 'Illustrations of the Geology of Sussex,' with figures and descriptions of the fossils of Tilgate Forest, among which he had found the iguanodon, the megalosaurus, the plesiosaurus, &c., and had made discoveries which will never be dissociated from his name. Indeed it is as a working geologist, as a discoverer, and as a collector, as a man who, in the infancy of the science of geology, placed before the world the means by which others could write a thesis or found a system, that Dr. Mantell's merits were best displayed, and will be honestly acknowledged.

"He received from the Geological Society in 1835 the Wollaston medal and fund, in consideration of his discoveries in fossil comparative anatomy; and in 1849 the Royal Society conferred upon him the royal medal for his memoir on the *Iguanodon* which was printed in the *Philosophical Transactions*.

"Dr. Mantell quitted Lewes in 1835. Among the patrons of merit which Sussex then possessed was the Earl of Egremont. He was a frequent visitor at Dr. Mantell's museum at Lewes, and mainly by his advice, and with a handsome donation of £1000, the residence of Dr. Mantell, together with his museum, was removed in 1835 to Brighton. The same amount of professional success, however, did not follow him from his native town, and, the Earl having died in 1838, and an attempt to keep the treasures in Sussex having failed, Dr. Mantell disposed of his collection to the British Museum for the sum of £5000, and himself removed in 1839 to practise at Clapham; whence he came to Chester-square.

"His professional practice was not increased by these removals, and latterly he had devoted himself more than ever to literature. We append the titles of some of his principal works, referring for others to the *Bibliographia Zoologica et Geologica* of the Ray Society, where the names of sixty-seven books and essays are given.

"*The Wonders of Geology*. 1838. In two volumes 8vo. This work consists of a series of lectures on the principles and facts of the science. It has gone through six editions, and has been translated into German.

"*The Geology of the South-east of England*. 1838. 8vo.

"*The Medals of Creation; or, First Lessons in the Study of Organic Remains*. 1844. Two volumes 8vo. This also has been translated into German.

"*Thoughts on a Pebble; or, a First Lesson in Geology*. Seven editions.

"*Thoughts on Animalcules; or, a Glimpse of the Invisible World revealed by a Microscope*. 1846.

"*A Day's Ramble in and about the ancient Town of Lewes*. 1846. 12mo.

"*A Geological Excursion round the Isle of Wight, and along the adjacent Coast of Dorsetshire*. 8vo.

"*Petrefactions and their Teaching*. 8vo. This was one of the last of the author's works, and was intended as an introduction to the organic remains in the British Museum.

"Dr. Mantell received a pension from the Crown during the last year, and had scarcely lived to derive any benefit from it. His doctor's degree was acquired from an American university. For the last few years he had suffered from a spinal affection, caused by accident, which prevented him from following his pursuits with his former activity.

"As a lecturer, as well as author, Dr. Mantell was eminently successful. His style was fluent, and he possessed the art of attracting his audience by an exhaustless catalogue of wonders. It has even been said that he yielded with reluctance to the revelation of a truth when it dispossessed him of a pretty illustration. It is certain that he depended much upon the arts of popularity, and he usually obtained all the applause for which he aimed.

"The Council of the Clapham Athenæum have publicly recorded their testimony of Dr. Mantell's last scientific efforts in that locality. They remark that 'For a long series of years the lectures delivered by Dr. Mantell in this place have formed one of the chief ornaments and attractions of successive sessions. No one who has enjoyed the advantage of hearing him can ever forget the singular ability, the felicitous illustrations, and the energetic eloquence which characterised all his discourses. He was one of the earliest and most zealous members of this Institution, and the originator of that series of gratuitous lectures on scientific subjects which have been so advantageous and creditable to the parish of Clapham. The members of the Clapham Athenæum will not be unmindful that Dr. Mantell's services were always prompted by an earnest desire to promote intellectual enjoyment and good-will throughout the neighbourhood; nor will they forget that these admirable lectures were generally delivered by him at the cost of much self-denial, under the pressure of severe bodily pain, and that the last public effort of this gifted man was made in the presence of the Society only a few hours before his lamented decease.'"—*Gentleman's Magazine*.

The following is a list of the *Horticultural and Poultry Shows* of which we are at present aware. We shall be obliged by any of our readers sending us additions to the list, and giving the address of the Secretaries.

HORTICULTURAL SHOWS.

SOUTH LONDON (ROYAL), Dec. 16.

POULTRY SHOWS.

BIRMINGHAM AND MIDLAND COUNTIES, 14th, 15th, 16th, and 17th December.

CORNWALL (PENZANCE), January 10th, and 11th. (*Secs.* Rev. W. W. Wingfield, Gulval Vicarage, and E. H. Rodd, Esq.)

HONITON, January 12th. (*Sec.* H. K. Venn.)

PINE-CULTURE: THE HAMILTONIAN SYSTEM.

(Concluded from page 160).

We have now the remaining heads—"Piping, Root-culture, Recipes, Ripening, Soil, Structures, Suckers, Syringing, Temperature, Watering, Ventilation," and then a few wind-up remarks; and we cry mercy of one portion of our readers, to whom this apparent repetition, or rather "summing-up" may be tedious.

PIPING.—For disposition of this in Hamilton's house, we may refer the reader to page 4 of *THE COTTAGE GARDENER*; and as a "Querist" has desired to know the calibre of pipes in that house, we beg to say that they are of five-inch bore, although Mr. H. observes they *might be* of four-inch. It will be seen, that there are two five-inch pipes in each bed for bottom-heat, viz., a flow and return; and that they are made to proceed to, and return from, an iron reservoir or tank at the farthest end; this saves the expense of elbow joints, we suppose, and is more simple. Two five-inch pipes also proceed along the south, and two along the north, turning round the end opposite the boiler; there also are a flow and return on each side, so that the house is fairly surrounded by piping to warm the air.

Now, as in hot weather the air-piping is not required on duty, Mr. H. says, on this head—"The pipes which heat the air of the house can be plugged up at any time, when only bottom-heat is wanted; this is a mode of my own, and simpler and better than valves." Our advice is, where you have any doubts about amount of piping, either call in an old practitioner, a man who is experienced in Pines as well as pipes, or else employ his fee in laying down a little of what you conceive to be piping which might be dispensed with; anything, in fact, but under-heating.

ROOT-CULTURE.—But little is requisite—still some is desirable. Mr. H. says in his book, page 65—"In conclusion I may state, that only when the roots are to be seen in the axils of the leaves, the operation of earthing-up is required; and it is better to earth-up *among* the leaves, than to destroy them before they have performed their destined offices for the plant." It will be seen, also, that in pot-culture, when an attempt is made to cultivate the old stool without planting it out, he prefers stem-culture, the old roots perfectly undisturbed, to repotting. He says—"I then commence earthing-up with the prepared compost, pressing it a little round the trunk of the plant, and allowing it to slope down to the edge of the pot. I am quite convinced of the superiority of earthing-up over that of transplanting into larger pots after the fruit has been cut. I have invariably found the plants to be from two to four months longer in fruiting, and the fruit also to be much inferior in size." We have here, as in a few other places, slightly paraphrased our author, but feel assured of pardon, the principles not being perverted, and, moreover, time gained. To conclude this heading, we may

repeat Mr. H.'s answer to our query, No. 19. *Question.*—How long after planting before they require culture, and what kind? *Answer.*—"All kinds would be better by a little soil on the top once a-year." By this our readers may see that a little up-stem culture, if not absolutely necessary, is particularly desirable; as soon as our beginners perceive, by observation, the natural habits of the Pine, they will be able to modify their practice to meet, not oppose, its own native bent.

RECIPES.—Mr. H., at page 58, very properly remarks, on insects—"I have known many persons, and have frequently heard of others, who, after having tried every method they have known, have at last been obliged to destroy their whole stock of plants in order to get rid of them;" that is to say, the insects which infest the Pine. Happily for beginners in these days, the rule has become the exception, and foul plants are so little known or expected, that even the wary may occasionally be caught napping in making purchases. No man in his senses would think of buying a stock infested with insects of any kind. If, however, such a case should occur, Mr. H. offers a well-tested recipe, which may be found at page 59 of his interesting work. This is for the cotton bug and white scale, two of the Pines' greatest enemies, and Mr. H. affirms, that "with one application every insect was destroyed without doing the slightest injury to the plants." Many recipes are to be heard of for destroying such pests, but we would fain for the present have the Hamiltonian system fairly represented; and, moreover, we have not space, and perhaps our readers have not patience, for digression.

RIPENING.—Little to be observed here. Mr. H., like all other good cultivators, prefers a somewhat drier air, and a previous abstraction of root-moisture, in order to obtain a high degree of flavour.

SOIL.—Let the reader refer to "Composts" in the present papers; this will save repetition.

STRUCTURES.—More will be urged another day as to what modifications of Mr. H.'s plan might be adopted; for the present, we will just observe, that Mr. H. has so far fallen in with views we have pointed out to him as to the span-roof system, as to admit the following:—"I am of your opinion, that span-roofed houses would be better north and south." Now, this has long been with us a favourite opinion; but as misleading an anxious public is not a light matter, we have, during the last three or four years, sought out opportunities of obtaining the opinions of those we deem first-rate practical men on this subject, believing that we were all held in a sort of thrall in the matter. We may here just point to our old and esteemed friend, Mr. Appleby, who has more than once (during practical chat) expressed himself as decidedly of this opinion; and, verily, the ridge and furrow houses all over the country would seem to bear testimony to a desire to seek some relief from the lean-to method; and not only that, but a sort of desire for a morning and evening slope to houses, in preference to a burning mid-day sun, with all the extras of shading, &c.

SUCKERS.—We have before given a detail of the culture of these, with the technical names by which they are known through subsequent culture. It may here be observed, that Mr. H., in strong terms, points to the immense progress they make attached to the old stool, as compared with those deprived of the assistance of the parent plant, by being entirely detached.

SYRINGING.—On this Mr. H. lays much stress. He says, page 42—"My motive for supplying the plant with a sufficiency of water, by syringing over the leaves, is twofold. First, I believe the leaves of the Pine to be very porous, and, therefore, capable of absorbing a great quantity of its food by that process. Thus, I syringe with tepid water. Secondly, By frequently syringing the plants, the surrounding atmosphere is kept in a humid state, the soil is constantly moist on the surface

of the pot, which causes a constant supply of food to descend to the roots from the fresh compost, and although limited, it will prove sufficient for their supply till the fruit is perfected; whereas, by this usual practice of supplying the roots copiously with water, the nutritious fluids are entirely washed out of the pot, &c." Thus it will be seen how it is that Mr. H. so very seldom waters at the root. The frequency of the syringings must in part depend on the weather, and the time of year; in summer, morning and evening; but in winter some caution is necessary—perhaps about three or four times a week. One thing must here be observed. Most good cultivators judge by the axils of the leaves, and make a point not to repeat the syringing until the axils of the leaves are nearly dry. This points at once to the necessity for a lively temperature, as well as motion in the air by ventilation.

TEMPERATURE.—Although we have briefly observed on air-heat before, we must add a little more under this head. Mr. H. says—"The temperature required for succession plants in the winter, is from 55° to 60° at night, and 65° to 75° during the day. In autumn, winter, and spring, if fruit are to be swelled, they will require 60° to 70° at night, and 70° to 80° during the day. In the summer, the maximum, under the effect of strong sunshine, may rise to 90°, and may be allowed to drop as low as 70° by the morning. In very bright sunny weather, the plants in fruit had better be shaded than admit too much air at any time of the day. In order to swell this fruit to a large size no air ought to be given until the thermometer reaches 80° to 85°, which will generally be by nine or half-past in the morning. To keep it down to this, give it the benefit of air until half-past ten, then close the house,—shade the plants, and water them over the leaves; then let them remain until half-past two or three in the afternoon; then unshade, and let them have all the benefit of light and sun, giving a little air, which must remain until half-past four, then close the house, and syringe again over the leaves of the plants, which will keep them moist during the whole of the night."

WATERING.—This is so seldom requisite under the Hamiltonian system that we merely refer to it in its order to keep the eye fixed on the fact. Of course, we mean watering at root by the ordinary water-pot.

VENTILATION.—Although Mr. H. seems to care less about this than most cultivators, it is his diurnal practice, more or less. Nevertheless, we do think that although for profit his plan is superior to any, yet those who aim at the very highest amount of flavour, and a small crown, would do well to go much beyond him in ventilating points. Of the close treatment, it may be safely affirmed, that it has a tendency to produce big crowns, and these certainly detract from the appearance of the fruit on the table. Mr. H. advocates shading occasionally. Now, the question is, whether east and west roofs would not obviate the necessity of this, and thereby save expense and trouble? We recommend those about to enter on Pine-culture to give this a thought, and, in doing so, to bear in mind Sir. J. Paxton's ridge-and-furrow roofs. We beg again to quote our good friend Hamilton in support of this—"I am of your opinion, that span-roofed houses ought to be built with the ends north and south; if they are not, there must be a good deal of shading, otherwise their leaves will be completely drained of their moisture. I speak from experience; they will have holes burned in them occasionally." It has been generally understood that the Pine requires a winter's rest, or, in other words, should be compelled to cease growing for some eight or ten weeks by a low temperature and a dry atmosphere. Mr. H., like most of the good people in the tall-chimney districts, is all for quick return for capital; and although he does not deny that the elabo-

rations at that period are less complete, yet he will not hear of loss of time, believing it—yea, knowing it—possible, by good management, to still push on (although by more tardy steps) the plants to the desired end. We here think, with all deference, that he carries the idea a little too far; but our readers will judge for themselves.

And now for a correction of errors into which we may have fallen. At page 24, an inadvertency occurs which will surely be pardoned, when it is considered that we have had to wade our way through, at least, half-a-score letters, and, in addition, to watch every idea set forth in Mr. H.'s book. One misleading point, which is a kind of ambiguity, stands thus—"The flow and return in each bed are totally unconnected with each other, or with the flow and return round the exterior, &c., &c." Now, what we really meant to express was this—that each bed had a flow and return of its own to provide the bottom or root warmth; and that each side of the house, north and south, was also, in like manner, fitted up for atmospheric heat. It was also stated, at the same page, that "there must be a great preponderance of heat at the boiler end;" this, however, it appears is not the case. We wrote to Mr. H. once more, after his repeated kindnesses, to invite criticisms as to mistakes, and he has at once set the matter right; for it would appear by his description, that his house is entirely surrounded by piping for the atmosphere, and to use his own words, "there is not half-a-degree difference between the ends." Thus: the boiler, we will say A, has a flow and return into the iron pan (which Mr. H. calls his cesspool), B. From this "cesspool," or, rather, iron-pan (which forms the medium of communication between the boiler and the pipes), proceeds along the south cavity, or alley, a flow, and, of course, return-pipe to and from a similar iron-pan, C, in the south-west corner; be it understood, that in this case the boiler is at the east end of the house. In like manner, a flow and return proceeds along the north cavity, or alley, to the same iron-pan; but this piping has to traverse the west end, of course, before it can reach the iron-pan, B. This will, we hope, render all plain; if not, we will try again.

To conclude, let us, on our own part, and also that of our readers, heartily thank Mr. H. for his very great civility in furnishing information. We owe it to a long acquaintance, doubtless; but, knowing the man well, there was a secret assurance that we might presume on his help. To be sure, it would have been much easier to have skimmed his book, and to have sketched an "article" out of it, which, indeed, could not have erred much; it appeared better, however, to have, if not new matter, at least a confirmation of the old, from the fountain head, and this a good feeling of long standing enabled us to obtain. But those who would fain know the minutæ of Pine-growing by his system, must lay by a few pence and buy his little book. An expositor, after all, is not an author; the public lie at the mercy of his views. In that original work, though small, though dressed in rude attire, and, we may add, not enriched by a high style of composition, may be found by the considerate a host of ideas, or the germs of them, carrying every mark of originality, and of a mind determined to test every previous practice by nature's own standard. We need scarcely observe, that in dissipating the idea of a chamber being a necessary adjunct to Pine-culture, he has done the gardening world no small service, for these chambers are expensive things. We do not say that he has been the first to get rid of this superfluity; he may, or may not be so; but if he is not, who is the man?

We have to acknowledge assistance from Mr. D. Davis, also, of Heaton-Lane Foundry, Stockport, who has been in the habit of fitting up Pineries on Hamil-

ton's plan. He has, it appears, a foundry of his own, and casts all his own pipes, guaranteeing any desirable amount of heat during the most severe weather. Mr. H. tells us, that he is highly qualified to give practical instructions in the way of erecting stoves, having had much experience this way. We have no personal knowledge of Mr. Davis, but Mr. H. points to him as one peculiarly eligible to those within his reach. Another hint:—Thomson, Esq., Greenmount Hall, Harpurhuy, near Manchester, has some true Jamaica Pine plants to dispose of; or those that are by some called Montserrat; which are, at all events, the best kind for winter, and by no means the worst in summer; added to which they are not, by any means, second as to cultivation on the Hamiltonian system. R. ERRINGTON.

BULBS.

(Continued from page 162.)

ANTHOLYZA.—The species of *Anizanthus* are now referred to *Antholyza* by common consent, but there is no feature by which they can be distinguished from *Gladiolus*, except the fore-shortening of the front or lower petals, that part being, as the botanist says, *abbreviated*. *Antholyza* being almost united to *Gladiolus*, through this section having the lip abbreviated, it is immaterial whether we join Sweet's *Anizanthus* to *Gladiolus*—their true position—or to *Antholyza*, whose flowers are more *Anizanthus*-like than like *Gladiolus* flowers. I never heard if these two forms of *Antholyza*, or even the *Anizanthus*, could be crossed with some of the nearest *Gladioli*, such as *Watsonias tristis*, and *concolor*.

The whole order of Irids, to which these plants belong, stands much in want of a thorough revision. Meantime, gardeners and amateurs might greatly assist in this reformation by instituting experiments, perhaps not so much for the purpose of increasing popular varieties, as to determine how far they will stand the test with the pollen. Try if *Antholyza Æthiopica*, *cunonia*, or *splendens*, will cross with any wild *Gladiolus*, or with any cross *Gladiolus*, that may have the flowers less regular than usual. Is it possible to cross *Antholyza* with *Watsonia*? Should these experiments fail, try them differently; let the species of *Antholyza* be first crossed with each other; *Watsonia* the same; and then see whether the crosses, or any of them, will unite the two genera, or fall back to *Gladiolus* through some one of its numerous crosses.

Antholyza Æthiopica, *cunonia*, and *splendens*, are the best three in this genus for the flower border, and they hardly ever refuse to grow in any kind of soil that is not too stiff. In pure, fresh peat they will luxuriate and produce abundance of fresh offset bulbs; the same in a deep, light, rich border of sandy loam and very rotten leaf mould; and they are more accommodating than the *Ixias*, for they may be planted any time from the end of September to the end of April. At the Cape, they would seem to be stifled in the hard brown coats and remains of the old bulbs, but that is the best condition for them to drain and throw off the wet from them, and with such natural guards they may remain for many years in a border without being disturbed. I have seen splendid examples of them in pots, in very rich, light soil, but not so good as I have seen them in an open border, being planted six inches deep, and supplied largely with water from the time the flower-stalks appeared.

Antholyza præalta.—This is the next best after the three scarlet ones, and, like them, it grows from two to three feet high. The flowers are orange with a tinge of red.

Antholyza montana.—This is comparatively a small plant for an *Antholyza*, and is much more like one of those curious species of *Gladiolus* one often sees from

the Cape; and when we remember that it was through *Gladiolus tristis*, the oddest thing you ever saw, that Dr. Herbert laid the foundation of the beautiful races of them which we now so much admire, dare we assert what is "looming in the future" of this *montana*?

Antholyza quadrangularis is another anomaly in its way—indeed, it would take a clever botanist to say what it is; and after that a few touches of the pollen might prove that it was no such thing. The flowers are narrower and less shortened in front than those of *cunonia* or *splendens*, and the colour is that faintish yellow which few admire; but the plant is as strong and as easily managed as *cunonia*, or any of the more fashionable *Gladioli*.

BABIANA.—A common observer could not tell a *Babiana* from a *Sparaxis*, nor some of the latter from *Ixias*, and some species of *Ixia* run so close to *Tritonia* that, without knowing the "private mark," no man could know the one from the other. The colour, size, or texture of the seeds is no criterion of generic differences among these *Ixia*-like plants. The insertion of the stamens, here or there, in the flower would carry the same weight with a pollen master. Versatile anthers, smooth or jagged spathes, and other marks of distinction, have been useful enough hitherto as "private marks" for telling present arrangement; but sooner or later the whole must be laid aside, and a reconstruction of *Ixias* be made; therefore, cross all the species as if they were in one genus already,—if they do not mix, that is no sign of a natural difference, and if they do, it will prove useful in two ways—an improvement in the garden varieties, and a check on the labours of the systematist. All the *Babianas* are quite dwarf plants, and more fitted for pot-culture than out-of-doors. They prefer sandy peat when confined in pots, but out in a border they will do without a particle of peat, if the soil is very light. Four inches is deep enough for the bulbs, and if a handful of clean sand is put round half-a-dozen of the little bulbs in a patch, they may remain undisturbed for several years. Whether in pots or in a border, they ought to be planted early in October, and not to receive more than the first watering at potting time until the leaves are well up above the ground; and there is not a plant in the whole order (Irids) that likes to be without a free admission of air during every period of its growth. There is about a score of species in this genus, but their culture being so uniform, I shall not waste space with separate accounts of them. Under *Sparaxis* I shall show a good way of growing a collection of such bulbs in the open air.

BARNARDIA SCILLOIDES.—This is a small, half-hardy bulb from China, with purplish small flowers. I think it was introduced by the Horticultural Society; at any rate, I recollect it as among the earliest plants that Dr. Lindley named on his own account. A figure of it first appeared in the Botanical Register in December, just twenty-six years ago, when I was at Altyre, and the late Lady Gordon Cumming sent for it at once. It did not seem to like pot-culture, and I have not seen or heard much about it these twenty years; but if it is in cultivation it is well worth having, as few bulbs of its small size flower at the same time—the height of summer. A light, sandy soil will suit it best; and if grown in a pot, the bulb ought to be freed from the soil as soon as it rests, and be kept in sand in a dry place; it might be so kept all the winter, and planted early in February.

BEATONIA ATRATA, curvata, and purpurea.—These are small Mexican bulbs, that are very nearly hardy. *Purpurea*, on which the genus was founded by Dr. Herbert, was discovered in Mexico, by Galeoti, growing along with the *Jacobæa Lily*, *Sprekelia formosissima*. All three refuse to grow in peat, and prefer a good, loamy soil, made light with sand; they grow and bloom during

the summer, and require to be kept dry from October till March. I believe the whole stock of them in the country were in Dr. Herbert's collection when it was dispersed, and that they are now very scarce. Naturally they are intermediate between *Tigridia* and *Cypella*, among the Irids. There is another fine *Tigridia*-looking bulb, growing on the top of the mountain San Felipe, in Oaxaca, in Mexico, which is not yet introduced, I believe; but it would repay a diligent search, and the range is not far out of the route from Vera Cruz to the city of Mexico.

BESSERA ELEGANS, *fistulosa*, and *Herbertii*.—These are also small Mexican bulbs, very pretty, and all but hardy. *Fistulosum* was figured in the Botanical Register, some twenty years since, from a plant flowered by Dr. Herbert, who called the genus *Pharium*; but it was pre-occupied by Schultes, and *Pharium* is now cancelled. *Herbertii* is among the newest of our Mexican bulbs. *Elegans* is the best of the three; the flowers are drooping from the top of the stalk, of a rich orange-crimson, and red stamens. They require exactly the same treatment as the *Beatonia*s; but their affinity is with the *Barnardia* mentioned above, being Lilyworts, of the Squill section.

BLANDFORDIA.—If *Anthericum*s were as gay and varied as *Alströmarias*, *Blandfordias*, and *Bomareas*, they would be equally entitled to a place in our series, for, properly speaking, none of them are bulbs, or corms either; but strangers and all who care little about looking under the surface of things, need not mind the roots when the flowers are gay, and look as if they were produced from real bulbs. *Blandfordias*, with all the aspect of bulbs, are, in reality, only herbaceous plants; their constitution is much stronger and hardier than their outward looks would indicate; indeed, no one who can flower a good Hyacinth three seasons running, need fear trying any of the *Blandfordias* without having more convenience for pot-bulbs than would serve to grow Hyacinths well. *Blandfordias* are from Australia; they belong to the order of Lilies, and to the section of Day Lilies in that order; and the nearest plants to them in that section are the *Tritomas*, from the Cape of Good Hope.

Almost all who like to grow the most showy herbaceous plants know *Tritoma uvaria* and *media*. A young plant of *Tritoma media* would look much like an old-established plant of *Blandfordia*; orange, crimson, and scarlet, mix in the flowers of both; both are increased from side suckers taken off in the spring, and some of the *Blandfordias* seed freely, but *Tritomas* do not seed.

I am not aware of any family of plants that have been yet tried by the cross-breeder, from which better plants for the mixed choice border could be expected than this and *Tritoma*; and, notwithstanding the difference in their flowers, I can see nothing in them to debar their union; get a cross between the old *Blandfordia nobilis* and *Tritoma uvaria*, and if it comes intermediate between the two parents, raising *nobilis* higher in the world, and reducing *uvaria* to the dimensions of an ordinary border-flower, where, among all the herbaceous plants, can such another gem be looked for? There is one thing, and one only, which is proved by cross-breeding, and that is, that if the pollen of a hardy plant, like *Tritoma uvaria*, is dusted on a less hardy one, as *Blandfordia*, the offspring would take after the hardier parent in constitution, therefore *Tritoma* should be the pollen parent. I shall never believe that these may not be crossed together, till all we know of the means of effecting a difficult cross are exhausted.

Blandfordia nobilis.—It was on this species that the genus was founded in 1803. A strong plant of it will throw up a central flower-scape two feet high, bearing a cluster of drooping flowers on the top, the colour being a rich orange-red. It seeds freely, and the seeds

ought to be sown the same day they are gathered; but they will keep for months. Good yellow loam, two-parts, and one-part of turfy-peat, with a little leaf mould and sand, is the right compost for full-grown plants; for younger stages, reverse the proportions of loam and peat, and leave out the leaf mould. But to see this plant in perfection, it ought to be grown out in the open air, in a deep rich border, three summers running, and to be taken up in October, and kept half-dry through the winter, or, what would be far better, to be left in the border, keeping frost and heavy rains from it in winter. All the other species have much of the family appearance; and after you know one of them, you would find little difficulty in recognising any of the genus—orange, crimson, and flame-colour, being the prevailing colours. There is a new and tall species that was little known at the time the genus was printed for THE COTTAGE GARDENERS' DICTIONARY. It was introduced by Mr. Low, of Clapton, with whom I saw it last October, and others of the same genus; the name is *Flamea*, or flame-colour, and they say it grows from three to four feet high, and is easily kept and increased. I linger for opportunity to try a crossing in this beautiful genus.

D. BEATON.

(To be continued.)

ALLOTMENTS.

WHEN duly attending to the higher matters connected with gardening and rural affairs, the interest of the labouring cottager should not be lost sight of. His condition and prospects have secured no little attention from the philanthropist. If schemes failed, the result was not the consequence of a lack of kind wishes. To improve any part of the masses of society there must be, combined with willingness, a thorough acquaintance with the condition, the intelligence, the modes of acting and thinking, of the parties to be benefited; without this the kindest wishes may not unfrequently enhance the very ills they are intended to lessen. Charity itself may be, and often has been, so administered as to militate against self-respect and independence of character. Without a trace of presumption, I have often thought that a committee of moderately intelligent gardeners, with their hearts in the right place, would be able to point out a better redress for many social ills than a more learned conclave of parlour-bred philanthropists, and just because most of us, though at times we take a pen between our horny fingers, have companioned and roughed it with the humblest classes of society in various parts of the country.

With the double flux that is now going on—the influx of gold, and the outflux of emigration—the question of allotments is not likely to occupy the prominent position it did several years ago, when, from several causes, there was a superabundance of labour. Still, as in rural districts good gardens exercise a great influence upon social comfort and moral worth, and as in suburban districts there will be joined, generally, to these advantages, the pleasures of change of scene and of occupation; while in both cases, as many a happy wife could tell, the patch of ground became one of the chief antagonists to the charms of the drink shop—our earnest hope is that these allotments may be vastly increased. Still, when a thing is so good in itself, we ought the more carefully to prevent its being turned into an evil; and having thought and observed much on the working of the system, years ago, I have taken the liberty of alluding to the matter here, to express how thoroughly I agree in the ideas expressed by Mr. Errington in the commencement of his article, page 149, and to hope that those opulent and benevolent individuals who nobly

contemplate extending the allotment system will previously think these matters over. Wishing, however, humbly to support Mr. E.'s opinion, I hope I shall be excused for stating the following deductions:—

1. It is always an advantage that the ground be contiguous to the cottage; next, that it be in a field as near as possible; and if at some distance, that it be approached by a good road.

2. The rent charged, after making allowance for any extras, should be similar to what the farmer pays for the adjoining land.

3. Whatever terms be agreed upon; whatever the conditions as respects regularity of payment; proper and industrious cultivation, and propriety of conduct, necessary to the holding of the allotment; no considerations of previous character, unless there was something very flagrant, should operate as a barrier to obtaining one; for to allow of such a barrier would be tantamount to denying our faith in gardening as an improving influence.

4. It is to the advantage of every labourer to be in regular, constant employment. The allotment or garden should be no decoy from his regular occupation. The extent of his holding should be regulated by what he and his family can accomplish during their own time. Few employers would refuse a man a day at any particular emergency, but this must not be calculated upon as a matter of course. I have met with few who will pay a man regularly and cheerfully in bad weather, who bolts off to his own ground without leave or warning when it is fine.

5. When a surplus of labour abounds in a district, the dividing the land into largish allotments, sufficient to give work for several weeks or months, has been considered a remedy. I am convinced it is merely a temporary palliative. It is based on the supposition, that when not working for the farmer the allotment holder can labour for himself; but unfortunately the farmer and the allotment want that holder's chief services at the same time. Need I speak of the tendency to grumbling, idleness, squatting, and the mutual heart-burnings thus produced?

6. If in rural districts such a superabundance of labour should again exist—as we have painfully witnessed in times gone by—two views as respects allotments present themselves. 1st. If it be conceded that the labourer is remunerated for his work on the allotment—and this, I believe, is generally granted—would not the same labour be worth somewhere about as much to the tenant or the landlord? and if so, might not the labourer be freed from a nondescript position, always an unpleasant one to be in? But, 2ndly. If capital is deficient to pay the labour seeking employment; and yet the superior cultivation of the land would remunerate the labour so employed, why should those able to support themselves for a short time from previous savings, and are willing to labour, not have an allotment that would give them work, not for a few weeks, but during the greater part of the year; a system which in such circumstances would ease the labour market, and prove a barrier to idleness and pauperism? I am aware that such an allottee would imperceptibly become a market-gardener, or a small farmer, thus opening up a great social question. I am, however, merely treating of *allotments* of land; and my object in addressing these words, not to the enemies of allotments, but to their advocates, and as such, the friends of the working classes, is to incite them calmly to investigate, whether between such a small farming allotment, and one that can be cultivated in the over-time of the family, there be, except in special and particular exceptions, any middle course, which, if continuously followed, will benefit, ultimately, either the individual or the community.

7. Some of these special exceptions may consist of jobbers, mechanics, and artisans, who do not expect constant employment at their avocations. The mere change of employment is to them a great advantage. Even here, however, some judgment must be exercised. I have seen men in such circumstances, attending thoroughly to their business, and yet producing specimens of cultivation that few blue aprons could equal. I have seen others trifling on their allotment, neglecting alike their business, and the interests of their family. A smaller or a much larger allotment would to them have been an advantage, just because many men, when much employed on the ground, lose all relish for other work. I have witnessed scores of cases of industrious tradesmen and mechanics, in villages, not more than half employed, their work having gradually lessened through no fault of their own, and yet, from a strong development of the bump of locality, they cannot think of going beyond the sound of the church bell to which they listened in better days. A large allotment to such men would be alike a source of pleasure, comfort, and prosperity.

R. FISH.

GESNERA ZEBRINA.

THE roots of this, after the tops decay, must be kept dry and free from frost. I have often kept them in the pots in which they bloomed, turned over on their sides in the warm end of a common airy greenhouse. A great lover of these plants has directed my attention to a passing notice of their culture lately, for greenhouse decoration in early autumn, by my friend Mr. Beaton, and has put a couple of queries respecting them, which may be generally interesting. 1st, Have you yourself found a similar system to answer? Yes, perfectly so. To obtain large masses of bloom early, either for vases or large pots, it is best to grow single tubers in small pots. Whether checked by being moved to a more cool, airy position, or not, they will show bloom much earlier than when supplied with more feeding room, and may then be turned out of their pots and be packed in the larger vessel. I have thus had fine masses in the beginning of August in a glass-covered veranda. 2nd, Is there not a discrepancy between Mr. Beaton's very easy method, and the great care detailed by you as necessary, some two years ago? I do not think there is. Mr. B. glanced at a system, without going into the minutiae. These little matters, I consider as important as ever, just because fine foliage, with a deep shade of purple, is more admired than even the flower spikes. Hence, care will be saved, when these plants can be started and grown in a hot-house, or forcing-house, where they can either have a slight shade, or be placed from two to three feet from the glass. A frame or pit will enable admirers to have these plants early, though assisted only with fermenting material; but my experience would direct attention to the following points: First, The heating material must be sweet. Second, Even then no steam or vapour should collect around the foliage previously to the sun shining on them. Third, Air should therefore be given night and day. Fourth, The plants should stand at a distance from the glass, or be slightly shaded from bright sunshine. Fifth, The drier the leaves are kept the better. Neglect in these matters will cause you to run the risk of pale, bleached, curled, and blotched foliage; and thus expose you to the loss of at least half the beauty of the plant.

R. FISH.

PERPETUAL CARNATIONS.

SOME of these were exhibited lately at Regent Street. I have understood they were first introduced from the continent by Messrs. Knight and Perry. I do not know how many varieties there are, nor am I certain of the right name of one of them. A friend pre-

sented me with cuttings duly labelled, but the man who planted them out managed to confound them as effectually as if he had shaken the tallies in a lottery bag. These matters some of our friends may give us information upon. Few that I have seen would suit a florist; but they are fine things for the lovers of flowers and sweet scents. They are well named *Perpetual*; but their great charm is that they bloom most abundantly, in autumn, out-of-doors, and in windows and greenhouses in winter, without wanting any forcing. I have seen them grown continuously in pots, with various degrees of success. I wish here merely to detail an outline of the system I adopted, with the results of which I am for the present satisfied. The cuttings were struck in a mild heat in the end of summer; when rooted they were docked to furnish more cuttings, which were struck by the end of autumn. Some of the first-struck were planted out in a border in autumn, and defended with evergreen boughs in winter. The rest, and the second-struck plants, had rough treatment in the pots in winter. All of them, the younger ones being previously stopped, were planted out, about six inches from each other, at the end of March, protected a little by evergreen branches. In May, as I wanted something to fill up a row of Cloves, I took the first-struck ones to do so. In August, September, and October they were noticed by every visitor, as many plants had a dozen of open blooms, with scores of buds to open. In August, the second-struck ones were carefully raised with balls, and potted, some singly in six and eight-inch pots, and others three in a twelve-inch pot. Many of these have been in bloom for some time, and others are in bud. Those in the line of the border, notwithstanding the wet, were still so full of bud and bloom, that I raised and placed a number singly in twelve-inch pots, a fortnight ago, and set them in a cold pit. They seem to feel the change but little. The obtaining such quantities of bloom from young plants, I attribute, first, to the stopping of the growth when young; secondly, to the planting out early in rich mellow soil; and, thirdly, to repeated manure waterings.

R. FISH.

CONIFERÆ.

(Continued from page 165.)

JUNIPERUS SPHERICA (Round-headed J.).—A species from the north of China and the Altai Mountains. Dr. Lindley has named it, and describes it as very beautiful. I have never seen it.

JUNIPERUS SQUAMATA (Scaly J., or Creeping Cedar).—A low growing, trailing shrub, seldom exceeding three feet high; a native of Nepal and the Bhotau Alps. Hardy only in the southern parts of Britain and Ireland.

JUNIPERUS TETRAGONA (Four-angled J.).—Of this species very little is known. It is a native of Mexico, growing on the road-side from Real del Monte to Chico.

JUNIPERUS THURIFERA (Frankincense bearing J.).—A native of Spain; a handsome, upright species, thirty to forty feet high.

JUNIPERUS VIRGINIANA (Virginian Juniper, or Red Cedar).—Native of America, in the States of Maine and Georgia, where it grows to a considerable size, rising to the altitude of from forty to fifty feet. It is very common in the nurseries in this country; and there are some noble specimens at Dropmore, the seat of Lady Grenville, and indeed in most gardens fine plants may be seen of it. The name Red Cedar is given to it because of the beautiful red colour of the inner wood. It is used as a case for black lead, but is not so much esteemed as the Bermuda Cedar for that purpose. The habit is pyramidal, the branches spreading partially horizontally when the tree is old, but in its young state they are upright, but even then not so close as the

J. communis suecica. As it is so plentiful in the nurseries the price is very moderate, even more so than any other Juniper, except the common one. The cause of its abundance arises from the fact that it ripens its seed in this country. The wood being of such a beautiful colour, and so valuable in other respects, combined with the cheapness of young plants, renders it a tree desirable to plant in quantities for the timber. It requires a deep, dry, sandy soil, such as prevails in Sherwood Forest, in Nottinghamshire. It is perfectly hardy.

There are several handsome varieties, though none of them surpass the species in beauty. They are *J. V. humilis*, *J. V. glauca*, *J. V. pendula*, *J. V. aurea variegata*, *J. V. Bedfordiana*, which is beautiful, and *J. V. Chamberlainii*. All these are desirable, and are ornamental objects for the lawn and the Pinetum.

LARIX (The Larch).—To the greater part of our readers this tree is well known, both on account of its good qualities as a timber-tree, and its having been planted in immense quantities in almost every part of England, Ireland, and especially Scotland. Though a native of the Alps of the south of Europe it was almost unknown to our ancestors. The country is indebted to a Duke of Athol for bringing it first into notice. He received two plants, cultivated them in pots, and kept them in a greenhouse till they were too large for the place; they were then planted out in two beds in front of the building, where they grew till they attained the height of seventy or eighty feet. Their perfect hardihood being thus established, seed was saved, and the produce planted out as forest-trees, and this led to their general cultivation as timber-trees. Millions of plants were put in on the Highlands of Scotland, which, on account of their quick growth, soon turned to profit;—this encouraged our landed proprietors to extend its cultivation still further; and it was soon found that the ground on which the Larch grew was greatly improved by the falling off and decomposition of its foliage, the Larch being a deciduous tree, that is, it sheds its leaves annually, which very few of the Pine tribe do.

A drawback has come upon the culture of the Larch, arising from the fact that a disease has attacked them within the last twelve or fourteen years. The tops begin to wither and die, then the side branches, and in four or five years the trees die. This has been particularly observed to have occurred to young trees of four or five years standing, but it is spreading to trees of older and larger growth. How far it will spread is of course unknown, but some measures should be taken to arrest its progress. I should advise every tree the least diseased to be instantly removed, root and branch, and burnt. I would also propose a query to all foresters and owners of Larch plantations, to this effect. What is the cause and probable cure of this serious disease of the Larch in Britain? It would not be amiss to procure seed from the Alps, as it is more than probable that seeds from diseased trees would produce a diseased progeny, or even the same effect would happen if the seeds were gathered from healthy trees growing amongst sickly ones. Then, again, the situation in which to plant this handsome tree should be attended to. If the land does not suit it, it will grow too fast, and become hollow in the centre. This is the case in low, rich land. The proper situation is on the sides of lofty hills, in thin gravelly soils. Though for the first three or four years its progress may be slow, yet it will make rapid progress after that time, and by the annual fall of its foliage enrich the soil under it; thus, feeding itself, as it were, by that means. Another important point is close attention to thinning in time, selecting the most healthy and promising trees to remain. These thinnings make excellent stalks for such flowers as Dahlias and Hollyhocks. The wood of this tree is very durable, hence these stalks will last longer than any

other kind, not even excepting the oak. The genus *Larix* is a small one; the following are the species:—

Larix Europæa (European, or Common Larch), *L. Sibirica* (Siberian L.), *L. Dahurica* (Dahurian L.), *L. Americana*, and *L. Americana pendula* (Weeping Larch), *L. leptolepis* (Slender Scaled L.), from Japan; not quite hardy in the north of Britain. Amongst these the Weeping Larch is a great curiosity, and worthy of a conspicuous situation in the Pinetum, but none of the rest are handsomer in growth, habit, and foliage, than the common Larch. T. APPLEBY.

(To be continued.)

PANSIES RAISED AND GROWN IN ENGLAND.

THIS list, in addition to the one sent me from Berwick, by the Secretary of the Eastern Border Horticultural Society, will form as complete a list as any amateur or dealer need desire.

I am sorry to have to report, that this autumn this favourite flower is suffering much from a disease, something in the same way as the potato. Many collections have almost entirely perished. In particular, I saw that both Mr. Turner and Mr. Bragg, of Slough, had nearly lost all theirs, not one in ten had escaped in the open beds; and that veteran in Pansey culture, Mr. Thomson, of Iver, in Buckinghamshire, informed me, a few days ago, that his stock out-of-doors were quite as bad. If these eminent growers fail, who can expect to escape? The cause and cure of this disease are almost as mysterious as the formidable potato murrain. I would advise every amateur that has a collection to preserve duplicates of his stock in pots, under cold frames, in order to ensure keeping them alive till spring. No doubt this very wet season has aggravated, if not caused this disease, and we may hope, if the anticipated dry frosty weather sets in this month, the complaint may be checked in its progress.

SELS.—FLOWERS WITH THE PETALS OF ONE COLOUR, WITH THE EYE DARK IN LIGHT FLOWERS, AND LIGHT IN DARK FLOWERS.

Adela (Turner); gold-yellow; fine form, and substance extra.

Cowper (Hunt's); canary-yellow, with a dense eye; a late variety. It was shown in fine condition at the Slough Pansey Show last year.

Crystal Palace (Thomson); a clear white, dark centre; fine form.

Commodore (Turner); a large, dark, mulberry-coloured flower, with a rich golden eye; large, fine, and constant.

Fair Maid (Byne's); the best white out; extra size and constant.

Flora Superb (Hooper). Another fine yellow variety, with a dark eye; fine form, and constant.

Goliath (Bragg); very large; dark maroon, yellow eye; fine form.

Hercules (Traicher's); rich mulberry; fine form and substance; size immense.

Ibrahim Pacha (Edmond); extra fine; dark mulberry.

Indian Queen (Thomson); fine dark purple.

King (Jennings); very dark; large and good.

Negro (Schofield); dark maroon; firm substance, fine form.

Nox (Hooper); dark crimson, almost black; good form.

Ondine (Oswald); fine white, with golden eye; a good old variety.

Ophir (Widnall); rich yellow, with dark centre; fine and large; if well grown, very few surpass this.

Pompey (Hale's); very dark maroon; rich texture; fine form and substance, and very smooth on the edges.

Pride of Iver (Thomson); extra fine form; very dark.

Polypheumus (Thomson); fine yellow, dark eye.

Pluto (Thomson); very dark, nearly black; good form.

Royal Purple (Thomson); extra large; fine form.

Royal White (Thomson); medium size; good shape and substance.

Swansdown (Turner); pure white; fine form; eye dark.

Sultan (Lorton); rich dark purple; substance excellent.

Smut (Hooper); shaded bronze, like *Satirist*, but larger; very distinct.

Viola (Thomson); violet-blue, black eye; very attractive, and a quite new colour; very distinct.

YELLOW GROUNDS, WITH MARGINS OF MAROON, CHOCOLATE, RED, BRONZE, PUCE, &c.

Addison (Turner); yellow, with red margin; novel; constant and fine.

Antler (Hooper); yellow, with a broad margin of purple.

Alexis (Gossett); yellow, with bronzy-purple margin; curious and fine; very distinct.

Amelia (Bragg); cream margin, with pale blue; very distinct and beautiful.

Ariel (Youell); yellow, with bronze-red margin.

Brilliant (Byne); yellow, with broad purple belt; fine.

Cæsar (Marsh); yellow, with dark rich maroon margin; fine and constant.

Comet (Thomson); fine show flower; golden-yellow, with crimson-maroon belting.

Crown-all (Thomson); yellow, with purple margin; the finest eye of all Pansies; form good.

Candidate (Thomson); cream, with broad purple margin; a good old variety.

Canopsis (Hooper); gold-yellow, with rich maroon edging.

Clio (Bragg); yellow, with narrow purple edging; very pretty.

Chieftain (Turner); yellow, with bronzy-red margin; very fine shape and substance.

Commander-in-Chief (Hooper); yellow, with red margin.

Diadem (Fellows); golden-yellow, dark maroon top petals, lower petals margined with the same; rich, and fine form.

Dr. Marsh (Marsh); golden-yellow top petals, and belting rich red; unique, and extra fine.

Elegantissima (Thomson); yellow, and bronze-red belting; much superior to *Elegant*.

Euphemia (Turner); straw ground, purple top petals and belting; very fine in early season.

Favourite (Hooper); yellow, and dark maroon belting; extra.

Fearless (Schofield); yellow, and dark maroon margin; fine form, smooth, and great substance; eye very dense.

Great Britain (Parker); yellow, margined with purple; extra fine shape and substance.

Great Western (Hooper); yellow and maroon; large and fine.

Hengist (Turner); yellow and bright red; novel.

Hero (Turner); yellow, and bronzy-red; very stout substance.

Joe Miller; yellow top petals, and belting bronze-red; new and fine; very distinct.

Laertes (Hunt); rich yellow, margined with dark maroon.

Lucidum (Parker); yellow and purple; fine form and substance.

Lord Walsingham (Thomson); yellow and purple margin.

Lord Derby (Thomson); yellow and dark maroon; fine, large, show flower.

Mrs. Bragg (Bragg); golden-yellow, rich mulberry-purple margin; a good old variety.

Monarch (Hale); yellow, with purple margin; extra fine.

Pandora (Hunt); yellow, margined broadly with rich, glossy purple; fine form and texture; and very constant.

Renown (Thomson); fine and large; extra shape and substance; first-rate; yellow and purple.

Rising Sun (Turner); bright yellow top petals, bright bronze-red lower ditto, margined with the same; fine.

Sir John Cathcart (Turner); deep gold-yellow top petals, fiery-bronze lower petals, margined with the same; extra fine substance and form.

Sir Joseph Paxton (Betteredge); yellow top petals, and belting rich dark maroon; fine shape.

Thisbe (Hooper); yellow and novel, bronze margin.

Timour (Bragg); bronze-yellow ground, with purple margin; distinct.

WHITE GROUNDS, WITH MARGINS OF VARIOUS COLOURS.

Albion (Thomson); white, margined with purple; dark eye; large and fine.

Blue Border (Boyd); white, belted with fine blue.

Blue Fringe (Major); white, deep blue edge; rayed; very beautiful.

Beauty (Thomson); white and purple; very fine and unique.

Climax (Bell); white, with broad purple margin; a good old variety.

Criterion (Hooper); white, with deep blue margin.

Eva (Thomson); straw, and rich dark purple margin; surpasses *France Cycote*.

Lady Carrington (Hunt); white, margined with light blue; novel and beautiful.

Lady Fair (Boyd); white, margined with puce.

Miss Caroline (Bouverie, Archer); white, with light blue margin; good.

Marchioness of Bath (Wheeler); white, belted with blue; bold, dense eye; fine form and substance; a good show flower.

National (Turner); white, with a broad, light purple margin; well defined; very smooth, constant, and fine form.

Queen of England (Fellows); white, with blue-purple belt; extra.

Rotunda (Hunt); white, margined with purple; fine form, and constant.

Royal White (Thomson); white, with dark margin; extra fine form and substance.

Sir Robert Peel (Hale); white, with fine purple margin.

Sylvia (Griffin); white, with a delicate, light blue edge; elegantly beautiful.

Venus (Byne); white, with fine blue margin.

T. APPLEBY.

FORCING POTATOES.

WHATEVER be the peculiar fancy of the epicure (and have we not all our fancies?), a dish of young potatoes is sure to find admirers at a season when the old ones (however good) have been sent to table until the appetite seems to long for a change. We all know how delightful it is to see the dish-cover unfold a progeny of young potatoes, instead of the old ones "served-up" in every variety of way that the ingenuity of the kitchen-department could suggest. Young potatoes create a sort of a *furor* for the moment; and the young, aged, and infirm, must all have a taste of the first produce of the season; but it belongs to a higher genius than mine to describe the feelings which this and other productions create on their first introduction; my duties are more

in the back ground, where the operations are at work which furnishes the article at the time wanted. Now, whatever may be the wants or peculiar fancies of certain individuals, we may take it for granted that every one is glad of young potatoes at the earliest possible time; and to accomplish this no time must be lost. The amateur whose means are limited, must look round and see if any vacant space in any of the heated structures is so far at liberty as to allow a few potatoes to be spread thinly over its surface. To exemplify this matter more, we will suppose that plenty of the earliest kinds of potatoes exist in the root-cellar, or other store. Now, in order to accelerate those intended for forcing as an early crop, a few must be put in heat as soon as possible, and afterwards they must be planted out into the hotbed, or other heated apparatus, where they are expected to produce their crop. Now, this preliminary progress on the part of the potato may be of a more homely or economical kind than that which furnishes them the means of supporting a progeny. We all know that a potato placed in a warm situation soon begins to shoot and grow, and we also know, that if these shoots are broken off, others succeed them in, perhaps, greater numbers, but much weaker. This second crop is not always sufficient to exhaust a strong vigorous tuber; but the successive efforts of the parent show too plainly that it must at last yield to such an exhausting process. A potato placed in a warm atmosphere will quickly show signs of life; the vital powers which Nature had intended to remain torpid until she called them forth in spring, are now put in motion by an agent, certainly not equally genial, but quite as warm.

Now a tuber or a bulb differs in many respects from a seed; the latter has stored away in itself the germ of a new plant, which it has likewise the power of preserving for a considerable period, or until it be placed in such a situation as to call its vital powers into action. On the other hand, a tuber, or bulb, is only the accumulated energies of a plant stored away for a limited period, which cannot be prolonged to any great extent, while it may be shortened by the forcing process very considerably; at the same time, some sacrifice, either more or less, must be made in securing this early produce. Now, though there are few things committed to the ground in the shape of seed, or roots, that present a more robust bulky appearance than a good sound potato, yet many eminent horticulturists affirm that it is not always sufficiently strong and well set to be able to support its offspring against the attacks of that disease of which we have seen so much, and know so little: whether this be the case or not, it is not necessary here to inquire; suffice it to say, that the stronger and more vigorous the set, the more likely it is to produce a healthy, good crop, other things being also favourable; it is, therefore, important that those required for forcing purposes be plump, heavy, sound tubers, and not by any means too small; the thoughtful economy which reserves those for seed which are too small for table must be suspended here, and sound, good, useful tubers of a tolerable size employed instead. This is the more necessary in the instance of forcing, because the nourishment and support which the parent set affords to its offspring is more required when in this artificial condition than when the young plant is luxuriating in all the advantages of the spring and early summer atmosphere; this latter differs considerably from anything which we attempt to imitate it in, consequently, a more liberal course must be adopted when anything like success is expected.

To the enthusiastic amateur, we therefore say, select at once a few good useful tubers of fair average size, which place in heat,—if in the light, so much the better; if not, it is not absolutely necessary; lay them

some four or five inches apart each way, on leafy mould, not too much decayed, and cover them up with the same. This covering is required only to prevent that loss the potato is subjected to if the surrounding atmosphere be dry; if moist, it is of less moment. Other substances might do as well as leaf mould, but none lift so well, or rather, nothing adheres so firmly to the roots of plants when it becomes necessary to remove them to another place; and this is important for this preliminary part of the process. Occasional waterings may be necessary, but this will depend on the state of the medium they are placed in, and other things. While this is going on, preparations must be made for their final transplanting into some congenial hotbed or other structure; in a usual way, a bed of leaves, tan, or dung, is appropriated to this crop; and though the early part of the process might as well be performed there as the after part, yet, as it would be difficult to ensure the bed retaining its heat so long as would be wanted for both, I have advised the preparation of the seed tubers to be carried on elsewhere, in order to husband the resources of the principal bed, or rather to delay the making of it until the potatoes are advanced as far as they can, with safety to their removal.

We will, therefore, suppose that the potatoes spoken of have sprouted and emitted roots in all directions, through the body of leaf mould in which they are placed; it is then necessary to prepare the future bed, which, if of fermenting matters, must be tested before the roots are trusted upon it. This is easily done by the means advised so often in the formation of hotbeds; and if the heat seems all right, and the frame and lights put on, a certain amount of good, light, and rather dry mould should be put on. This may remain a day or two until it gets properly warmed, when the potatoes may be removed from their nursery-bed, with as much of the leafy mould adhering to them as will do. These may be planted in rows, about fifteen inches apart for Ash-leaved, and similar short-topped kinds, and proportionably more for the larger-growing kinds; about a foot, or it may be less, between set and set in the rows. There is usually a tendency to crowd plants in a frame. The object of a litter for seed seems not of much consequence; but it is questionable whether this overcrowding be attended with the required benefit or not. The soil in the frame being warm, and the lumps of leafy matter adhering to each tuber, the check cannot be much if due care be taken in the planting, and other things favourable to their growth be attended to. It is almost needless to observe, that a full south exposure must be had for the frame, which must not in any way be shaded by trees or buildings on the sides on which the sun shines; the reverse sides may be as much sheltered as can be, always bearing in mind that the shelter of over-hanging trees is shelter with a vengeance, even should it be on the north side of the object protected by it; but more of this anon. J. ROBSON.

THE VILLAGE FEAST.

By the Authoress of "My Flowers," &c.

THE Word of the Lord declares that he is "blessed" who "standeth not in the way of sinners." Every day we see the truth of this inspired assurance, either in the quiet and prosperous condition of those who keep out of the way of the wicked, or in the punishments and troubles that come down upon those who set at nought the righteous commandments of God. Many a man has kept company with those whose ways were crooked and evil, while his own were decent and respectable; but he has either been obliged to break with them at last, or he has suffered in his own body, or his precious soul, for "walking in the way of sinners," and seen, when it was too late, that the only way of peace and safety is in obeying the commands of the Lord.

The young are especially inclined to be careless about the character of their companions. They are quite content to know and be seen with idle, worthless, young people, if they are not themselves guilty of the follies and vices they walk beside; but, alas! evil, bitter, *eternal*, are the consequences of such careless indifference to sin and sinners; and it behoves all, high and low, old and young, to "stand not in the way of sinners," for a worse end than "sitting in the seat of the scornful" may be their portion—an end that admits of no repentance, and no hope of eternal life. Let my younger readers read, ponder, and lay to heart, the true and terrible story of George Griffiths.

He was a young man of very quiet, inoffensive habits, by no means one of the idle, profligate youths that infest the village, and the persons who employed him spoke well of him. His mother had not been what a mother ought to be in some respects, but she was fondly attached to him. She was the wife of a second husband; but the son of her youth was good to her, and a comfort in the declining years of her life. She had been struck with paralysis also, and had been for some months confined to her cottage in consequence.

There is, in some parishes of England, an annual abomination, called a "Feast." What it takes its rise from I do not know; but it would be a parochial and social blessing if such seasons of riot and drunkenness were discountenanced, and wholly put down; for the only effect of them that is visible is the drinking, disorder, and confusion of the village, and the interruption of work, and squandering of money that invariably takes place at that time. There is generally dancing, penny shows, and such snares laid for the young and giddy; the beer-houses are all as busy as bee-hives; and drinking, finery, and idleness, is the order of the day. Fathers and husbands will spend in one day the week's food of their wretched families, and give up work for that day, and often the next to it, to revel and drink away their senses.

At the last Feast of the parish in which George Griffiths lived, the awful scene took place which I am going to relate. George had been amusing himself with the rest of the community, but in a far more harmless way than many. The beer-houses were full of intoxication, but he was not a drinking character; and although he was amongst the ungodly throng, his head was clear; he had had beer, but was quite sober, and only excited by his high spirits, and the scenes of vain and shocking mirth around him.

One of his companions became so totally intoxicated, that George undertook to see him safely home, as their way was, for some distance, the same. It was late, but the brother of the young drunkard rose and let them in. Instead of going immediately and steadily home, Griffiths was induced to take a glass of spirits at this house, and, in spite of his previous caution, he swallowed a large draught of gin. Then he quitted the house on his way to his mother's cottage.

The next morning, when these two young men got up to go to their work, they found the body of a man lying not far from their door, with his head resting upon some brick-work. It was the almost lifeless body of George Griffiths. Stupified with the gin, he had slipped or stumbled, and his head had come violently down upon a row of bricks or stones, which had caused concussion of the brain, in which helpless state he was found by the very youth whom he had taken home, the evening before, in a state of frightful intoxication. The poor mother's anguish may be imagined, but can scarcely be described, when her son was brought home to her. He lingered through the day and night, and then his soul "returned to God who gave it."

Thus ended the short life of a quiet young man, who stood "in the way of sinners." It is a solemn warning—more solemn than the death of an open sinner, because all see and confess the guilt of open and undisguised sin, and thank God in their hearts that they are not as open sinners are; but they do not see the guilt and peril of quiet lives, when there is no work of grace in the heart. This awful death has set before a whole parish, and all who hear and read it, the startling truth, that they who "stand in the way of sinners" are in peril of everlasting destruction. No man is *quiet* in the sight of God, but he that has sought and found the "kingdom of God and his righteousness;" for "the work of righteousness" only "shall be peace; and the effect of righteousness, quietness and assurance for ever." Quiet lives before men are only hollowness and

deceit; they deceive ourselves as well as others; we say to ourselves "peace, and there is no peace." We are on the road to ruin.

Did George Griffiths suspect, when he undertook to lead his reeling companion safely home, that he was himself to die in a state of intoxication within an hour? Had any one whispered such a thing to him, he would have said, with Hazael, "Is thy servant a dog, that he should do this?" He would have turned away in anger and unbelief. But he was "standing in the way of sinners;" he was in the company of ungodly men; he had no friend by his side to lead him safely on. Satan was at his right hand. The bottomless-pit was open before his feet! Past finding out are the ways of a wise and righteous God! The open sinner still lives, to fill up the measure of wrath, or to "turn from his wickedness and live;" while the quiet sinner was cut off and struck down in a moment; a loud and solemn lesson to all who are leading *quiet* lives, but have, in their hearts, departed from the Lord.

A season of great and glorious rejoicing is at hand. It is a time set *apart* for *spiritual* thankfulness and praise; but it is made a time of feasting and vanity, of revelling and drunkenness, of idle and worldly merriment. Let the young be warned to flee from the evil to come! Let them remember the quiet life and dreadful death of poor George Griffiths. Let them not seek amusement in places where God is not acknowledged, and among persons who regard Him not. Let them remember, that though Jesus Christ died for our sins, He lived as our example, that we might walk in His steps; and, that they who lead quiet lives, and say at stated times "Lord, Lord," are not entered into the kingdom of heaven. Oh, let them beware of those false hopes and bitter delusions! Let them rest in nothing short of conversion of the heart to God, and acceptance of the righteousness of Christ, as our only justification. Let them flee from the company and ways of sinners, as they would from pestilence and roaring lions, and let them *keep the commandments of God*.

Had George Griffiths lived a holy as well as a quiet life, had he known Jesus Christ and Him crucified, he would not have dared or wished to company with those who defied God's law. Then it would have been well with him. But he stood in the way of sinners, and rushed with a brain on fire into the presence of his Maker! Let the young man lay this lesson to his heart; let him serve and worship God, and take warning by the death of poor George Griffiths! There is no repentance in the grave.

VISITS TO SOME OF THE CHIEF POULTRY YARDS OF ENGLAND.—No. 4.

(PENZANCE.)

(Continued from page 130.)

We did injustice to Mr. Blee's poultry, at page 129, in not explaining that the weights there referred to were taken on the 22nd of September. The cockerel No. 1, in the table we published, weighed, at the beginning of November, 11lbs. 6oz.

At Rosevale, in the immediate vicinity of the town, Mr. Bowman, who, with some few others, laid the foundation stone of the "Cornwall Poultry Society," by exhibiting, in the field of the Penzance Agricultural Show, in 1851, certain pens of poultry, which, even then, attracted great attention, has brought together a most valuable collection. But before we enumerate the many beautiful specimens of which he is the owner, it would neither do him justice to pass over the admirable design and arrangement of his fowl-houses; nor would it be fair to those who may be anxious to avail themselves of the practical knowledge which he is at all times ready to communicate. Built of brick, slated, with floors of the same material, they defy the incursions of rats and mice, formidable foes when once they effect a lodgement in such places. Each division has a separate yard, with curiously devised little latticed passages, by which, in some cases, the sleeping-rooms are reached when a direct communication is not attainable. The roosting-places for Cochin-Chinas should always be low, say 20 inches; but many of these birds prefer a board to a perch. But let us now go carefully through his list.

Two Punchard hens, which, with the cock, won a prize at Birmingham, in 1850, first meet our view; the scales being at hand, the weight of one proved nearly 8lbs., heavy for the time of year (September), when the laying season ends, and the moulting draws so heavily on the constitution. Exceeded as this race now often is in point both of colour and size, they will always be valuable for crossing with other Cochin-Chinas, where substance and short legs are desired.

In an adjoining court are the elder white Cochin-Chinas, bred from the stock of the Dean of Worcester; the cock now weighs 9½lbs., and his symmetry and breadth of limb are so striking as induced us to ask Mr. Bowman for his measurements. Below will be found the weight of a son of his, of glossy plumage, and, we think, most perfect form. He is here measured and weighed side by side with his parent.

	COCK OF 1851.	COCKEREL HATCHED FEB. 12TH. 1852.
	inch.	inch.
Length of bill	7 $\frac{2}{3}$	8 $\frac{2}{3}$
Length of neck	7	8
Length from neck to rump....	14½	12
Length of thigh	8	9½
Length of shank	4	4½
Girth over wing, before legs ..	24	23½
Girth over wing, behind legs ..	24	20
Girth of neck, lowest part	12	13
Girth of neck, by head	7	7
Girth, the back part of thigh..	7½	7
Girth of shank	2½	2½
Breadth across wings	9	7½
Weight	9½ lbs.	8½ lbs.

Such weights speak for themselves. Mr. Bowman informs us that he has already disposed of a considerable number of the white chickens of this year, and as several of the pullets were in proportion equal to their brother, no wonder the demand should be great. Two that were weighed before us, though much younger than the cock, weighed respectively 5½lbs. and 5½lbs. An extensive range of ground under some young trees, and surrounded by net, affords a capital run for his pullets. A few evenings since Mr. Bowman was somewhat later than usual in shutting them up for the night, and the passage leading from this enclosure to their home being narrow, they had crowded one on another at its extremity, where the door was shut against them, till they were tier upon tier—three of the lowest were insensible, and one dead; whether any fright, or mere desire of retiring to their nights repose caused the "black hole" catastrophe does not, however, appear. Mr. Bowman possesses a remarkably fine, light-coloured cock of last year, which formed one of the pen, No. 212, at Birmingham, in 1851, purchased by himself and Mr. Blee, and which carried off the 2nd prize for chickens. His carriage is exceedingly upright, the back hackles like golden spangles, drooping richly over the wing, also the arched neck, in our opinion, distinguishes this breed in a remarkable degree.

We also saw some golden Polands—birds, if we mistake not, from the stock of Mr. Vivian, of Swansea, a Birmingham winner. The full globular tuft of the pullets, while that of the cockerel falls backwards on the neck, like the crest of an old helmet, with the clear ground colour of their bodies will, we think, ensure their registration as, A.I.

Nor must we forget among all these treasures some coal black Cochin-China chickens, hardly old enough as yet to display the rich tints assumed by these birds in a mature state, but indicating even at this early age so many good points in figure and proportion, that we doubt not, but that in due time they will realize most fully all that is now hoped of them. This colour, we should remind our readers, is infinitely more rare than either white, buff or partridge. Some of the birds showed a little gold on the hackle but several were coal black.

Many of our readers will be surprised, we imagine, when they are informed of the extent to which the amateur in poultry often extends his transactions. Mr. Bowman, who for four years has devoted so much time to this his favourite pursuit, has most kindly permitted us to mention the following facts, which illustrate very fully the observation just made.

During the present year the amount stands thus:—

Number of eggs sold	374
Ditto hatched at home.....	349
Chickens sold to this time	138
Present stock	117

The eggs were sold at prices varying from 21s. to 36s. per dozen. The chickens at from 21s. to 42s. each, excepting some few objectionable birds which realized from 10s. to 15s. each.

But let it not be supposed that such returns are attainable by every one, who, seeing the prices here realized, rushes into poultry-keeping without that practical knowledge of its various details which has occupied Mr. Bowman's attention for so long a period. If, however, in defiance of our warnings, he is rash enough to do so, the chances of failure and disappointment are indeed great.

Many are of opinion that eggs are greatly injured for sitting by having to travel any considerable distance, and doubtless it would be better to set them without incurring the least risk from being shaken; but the result of the chickens produced from 374 eggs sent away this year by Mr. Bowman, has been highly satisfactory to those who obtained them from him. One curious instance, bearing on this point, was mentioned by him. "Six eggs, of buff Cochín-Chinas, were sent by omnibus to Hayle, thence by steamer to Bristol, on by rail to Oxford, and there forwarded about 25 miles by coach; after so long and so varied a journey as this, six chickens were, nevertheless, produced from the six eggs."

No less than 14 English counties, as well as various places in Scotland and Wales, have received eggs and chickens from Mr. Bowman during the present season. While speaking of eggs, he remarked, that much had been said about their not hatching well this year, but that, in his own case, he considered himself to have been very fortunate with his very early broods—eight nests, of 11 eggs each, having produced 80 chickens, all of which, but two, which were crushed by the hen when a day or two old, lived and did well; but, he added, "I did not do so well later in the season." Besides what has gone into other parts of England from Mr. Bowman's stock, Mr. Blee has also sent away as far north as Halifax, and beyond London in an eastward direction, more than £30 worth of Cochín-China eggs, beside many young birds averaging from 21s. to 30s. each. His correspondents having given him in most instances an account of the chickens hatched from their eggs—he places the average at 8 eggs out of 11.—W.

(To be continued.)

POTATO GROWING.

PERMIT US to offer, for the *public good*, the extract from our Treatise on Potato Culture, hereafter described, which we trust needs but the thirteenth word, *early*, to be strengthened by an additional syllable, *EST*, to make it complete. On the former, much stress should be laid, and a still greater emphasis on the latter, on which all success depends, whether they are cultivated, or planted by our method therein explained, or not. By a strict adherence to this part of our treatise, and especially the identical word above alluded to, no one need fear diseased Potatoes, and we vouch for good results, believing that Potato disease, by the Divine interposition of Almighty God, will yet prove a blessing rather than a curse, inasmuch as the main crops of wheat or barley in double rows, at wide distances, five feet apart, may be combined with Potatoes with perfect success, and after-crops of many descriptions may also be introduced amongst them with equal profit, such as mangold wurtzel, turnips, and most other garden productions, or, where necessary, whole clean fallows may be made; whereas, formerly it was often with difficulty that land, after potatoes, could be got ready, except in a bad condition, and late in the season, for sowing wheat upon.

We cultivate several varieties of the *earliest* dwarf selected kinds, and have none diseased, simply for two reasons, namely, *planting early*, and planting the *earliest* varieties, which ripen their tubers about the time of the summer equinox, or at the end of June, before which time but few fears need be entertained of disease in the Potato, as it has

not hitherto manifested itself before this time, except in a small degree. We have no objection to other kinds of manure being applied besides what is recommended in our pamphlet, nor do we see any reason why *EARLY* Potatoes should not be highly manured, in order to forward their growth before and after they appear above ground, and when devoid of moisture, so often experienced in the month of June, as well as in providing for after-crops. The evil of using manure is confined to late planting, which practice (without arrogance to ourselves) it is found necessary, under present circumstances, to denounce altogether, for, whatever the kinds may be, all are thus attended with bad results.

Some part of our treatise, not hereafter inserted, not being adapted to the present seasons, as we find from experience, requires revising, and is under our immediate attention and correction.

The use of small Potatoes for planting is only recommendable in cases of emergency like the present time, and for those who cannot afford to buy larger ones, and the guidance of the *public good*, we freely subjoin the following communication:—To plant one acre of land with large *earliest* Potatoes, 4 ozs. each, at one yard apart, requires 21½ bushels of per 56 lbs.; present value about £5. To plant it with sets half the size, at the same distance, of course requires 10¾ bushels; value about £3. And to plant it with sets 1 oz. each, of the common size, now in use, at half the distance, viz., half-a-yard apart (ample space), takes about 10 bushels per acre, equal to a quarter-of-a-peck per rod; present value, say £1 10s., of early selected varieties. Experience has taught us, repeatedly, that large sets produce the most lucrative crops; but it is to be regretted that so few persons can now avail themselves of this opportunity.—ABRAHAM HARDY AND SON, *Seedgrowers and Seedsmen, Maldon, Essex.*

An Extract from "Culture of the Potato."

"The first point of importance is the selecting or procuring the best early dwarf kinds, and such as have escaped disease; and, secondly, the time and manner of planting, so as to improve their early habits.

"Any time from September to the end of April may be chosen for planting any kind of Potatoes, provided the weather is mild and dry, the latter being most essential. The land, too, should be in a dry and pulverized state previous to planting, which object should be effected and persisted in, by forking it over and over, as may appear necessary, in dry weather.

"If it is desired to plant previous to March (which we highly recommend), the land being brought into proper tilth, as above prescribed, should be marked into drills four or five inches deep, and twenty-seven inches apart, and the sets or whole potatoes of a middling size, say as large as walnuts, should be planted nine inches distant, with about a teacupful of coal-ashes and soot heaped over each set, to prevent the attacks of intruding insects and frost. Then, with a hoe, cover them with the light dry mould, forming a slight ridge; and lastly, let the whole be completed with the spade or plough, raising the said ridge as high as possible, so that the drill forms exactly the centre. The sets thus secured from wet, frost, and insects, no further care is necessary till the end of March, when the whole may be forked down level, and treated in the ordinary way."

GROWTH OF SHANGHAE FOWLS.

As you have considered the facts contained in my last worthy of insertion in your journal, I beg to continue to report progress. The increase in weight during the fourteen days has been from 9½ oz. to 22 oz. each bird; a greater average than on the previous occasion; but it will be perceived, by the annexed table, that some of the pullets have increased far more than others. None had laid before last week; three then commenced, and laid twelve eggs; which were the three, I am not sure, but think them to have been Nos. 2, 4, and 5. I should add, that three of them were, during six days out of the fourteen, either travelling or shut up and in a pen at the Hitchin poultry show; and I have no doubt they lost weight during those six days, otherwise the total average would have been greater. We will suppose

these pullets to have cost in food 3d. each per week, the total would be for the fortnight, 4s. The total increase in weight is 7½ lbs., which at say 5d. per lb., is 3s. 1½d.; and 12 eggs, at 1½d. each, 1s. 6d.; makes a total of 4s. 7½d.

I do not consider the cost of the food should be set down at more than 2d. per week, but supposing it to be 3d., does not the above account speak in favour of the Cochin-China breed?

I think the result of the present controversy will show that Cochin-China chickens cost to rear more than other breeds, just in proportion to their superior value on account of weight; and that Cochin-China fowls cost less to keep in the proportion of the lesser weight of their eggs. We have, then, in favour of the Cochin-China breed, the size for table use, the beauty and docility of the birds, the richness of the eggs (and if kept on a large scale, the superior value of the feather). In time, I think, a general preference will be shown for the flavour of the flesh of the Cochin-China, and then the slight objection to the colour will vanish. In breeding, it will be desirable to keep the legs as short as possible; and on this score, in a short time, we shall no doubt be perfect.

In my above calculations, I have, of course, not considered the present high prices of good birds, on account of their scarcity; first-rate birds will, no doubt, be always of much value. But our aim should be to show that, for general purposes, the Cochin-China breed decidedly deserves to be the favourite; to show that the cost of their keep is certainly not proportionately greater than that of other breeds; and that in every other respect they excel all other kinds of domestic poultry. I beg to annex the list referred to at the commencement.

	Pullets Hatched.	Weight Nov. 13. lbs. ozs.	Weight Nov. 27. lbs. ozs.	Increase. ozs.
1.	May 15	6 13	7 6½	9½
2.	May 25	5 13½	6 13½	16

—WM. JNO. BEEBY, *Chaldon, near Coulsden, Surrey.*

LONDON FLOWER MARKETS.

How are we to account for the very remarkable fact, that whilst Paris has *five markets*, exclusively devoted to the sale of flowers, London has not *one*? It is true that flowers are sold at Covent Garden, but then they are of secondary consideration, and are so mixed up with fruit and vegetables, that a proper display of them, or suitable accommodation for purchasers, is out of the question. Those who cultivate flowers for sale may justly complain of the want of a proper site for the exhibition of their productions; and the citizens of London may fairly urge their need of a better supply. The love of flowers may be said to be universal; it is an inherent part of our nature, and it is not too much to expect that if a suitable market was established, and placed on a right footing, the sale of flowers would be increased ten-fold. When in London, a short time since, I noticed upon the parlour table of the boarding-house at which I was staying, a vase of flowers, looking very withered and pitiful. On my remarking their appearance to the landlady, "Ah," said she, "we cannot get flowers in London as you do in the country; that nosegay cost me one shilling, and then I had to pay sixpence more by omnibus for going and returning from Covent-Garden to buy it, but it shall be replaced with another to-morrow. I love flowers, and would have a nosegay every other day if I could afford it; as it is, I am obliged to be content with one in a week." Now this good lady represents a numerous class who experience the same want; and there is still a larger, with whom this difficulty of obtaining flowers amounts to a prohibition of their enjoyment; even the opulent would like a better supply. Then we shall soon have the Crystal Palace, with its extensive flower-gardens, which cannot fail to give an additional stimulus to the love of flowers, and an increased desire to possess them. Why should not London, then, have a good flower-market, seeing that there is a demand on the one hand, and an ability to supply it on the other?—S. P., *Rushmere.*

DORKINGS *versus* SHANGHAE.

I AM certain no man can give fowls a fairer trial than I have done for the last ten months with the Dorkings, I having reared nearly one hundred of each sort, and have no other motive in view than to find out which is the best sort to keep. Now, the result of my trial is quite different to the account of "Shanghae Mandarin," as I am able to point out. My Dorkings were an old breed I have had for years; my Cochin-Chinas were from the very best breeds, which I purchased for a very long price, wishing to begin with the best. My first hatch was on the 12th of March, having seven Cochin-China eggs and six Dorking eggs under one hen; the produce was five Cochins and four Dorkings, which were all reared under the same hen. At ten weeks the Dorkings were very nice fowls for the market, but the Cochins had not a feather on them. At fourteen weeks I killed a cockerel of each sort, and weighed them very carefully, the Cochin-China was four ounces the heaviest, but I am certain one Cochin eats quite as much as two Dorkings; then they were both cooked together, and served up on one dish; the Dorking was a fine plump fowl as could be, but the Cochin was ugly, and looked as if the cook had given him a coat of yellow paint before she sent him in—the Dorking was of rich white flesh, and the Cochin very little but bone, and although the Cochin was four ounces more weight, the Dorking was worth two of him as a table fowl. The only point where the Cochin-China can have any preference is their laying; they certainly are better layers, but in no other point can they equal the Dorking; and I am convinced, from my trial of the Cochin-Chinas, that they are not the fowls for a cottager, who must have something that will come sooner to profit than the Cochin-Chinas, if he has no other way to dispose of them but in the market. I am certain he can rear Dorkings for very little more than half the cost he can Cochin-Chinas, and he can take his Dorkings to market at three months old, when he must keep his Cochins five months, unless he takes them without feathers on, when they would look more like young owls than poultry going to a market, for they do certainly look curious things in that downy state in which they remain so long; and any cottager commencing with Cochin-Chinas will very soon find out his mistake, for they are not like other fowls, straying off and finding food for themselves, but standing moping together all day, entirely depending upon what you give them, and that never comes too often, nor in too large a quantity. Now I am not writing what my man has told me, nor what my poultry-woman has told me, but from practice, as no other person has given my fowls one handful of food but myself, and after ten months fair and impartial trial, I have perfectly satisfied myself that the Dorking beats the Cochin-Chinas ten to one.

I would ask "Shanghae Mandarin" what will become of his Cochin-Chinas two years hence, when there is no other way to dispose of them but in the market. What sort of a figure will they cut in a market beside a lot of nice Dorkings at three months old each? they will be laughed at, whilst the Dorkings will find a quick sale, and then will be the time when the cottager will find out which is the best to keep. I am certain my Dorkings are in better condition with what they can find in a farm-yard and a grass-field to stray in, than the Cochin-Chinas are with as good a walk and a very great deal of artificial feeding, and will surpass them in weight; to be certain of which I have just weighed them before I write, making choice of the best of each, and of these I give you the list:—Dorking cockerel, hatched April 1st, 8lbs. 8ozs.; pullet, sister to him, 6lbs. 12ozs.; hen, eighteen months old, 8lbs.; Cochin-China cockerel, hatched March 25th, 8lbs.; pullet, sister to him, 7lbs.; hen, twenty months old, 7lbs. 12ozs. The Dorkings are of my own breed, and the Cochins from a Sturgeon's hen. What will "Shanghae Mandarin" say to this? I have no doubt but some of the Cochin-China breeders will say that they can beat this in weight, and so they may; but not without a very great deal of artificial feeding. Perhaps, too, they may say it is a great weight for the Dorking, and so it is; but they must be of a pure breed, not like some that a well-known exhibitor brought out last year at Birmingham, crossed with the grey game fowl to get the rich colour. He got the colour, but lost the size, which did

not escape the judges' eyes, and satisfied them that they were mongrels.

I think I have said enough to show that the Cochin-Chinas cannot have much preference over the Dorkings, whatever they may have over other fowls; but I hope some of my black Spanish friends will let us hear something of their merits, and not let the Cochin-Chinas carry the laurels which they really do not deserve; and I am certain the time is not far hence when the good old Dorking will again assume the same place as she has done for so many years, viz., second to no fowl as yet known.—FAIRPLAY.

[Our correspondent certainly had not pure short-legged Shanghae's, and he forgets all their good qualities so frequently pointed out in our columns.—ED. C. G.]

HONEY HARVEST IN SOUTH LINCOLNSHIRE.

I TAKE much interest in reading the remarks in *THE COTTAGE GARDENER* by Bee-keepers, and if you think well, I will add my share to the information that has already appeared in your columns, on the past season.

The year has been a very peculiar one with us, in the south of Lincolnshire, and the adjoining county of Rutland; and from thirty apiaries with which I am acquainted, there has been, with one or two exceptions, but little produce. In some of the villages in Rutland the swarming began early. I heard of several swarms on the 9th of May. In one village, which is well wooded, and where the clover was very good, the harvest was considered an average one. The cottager who commenced the year with eight stocks, had nineteen swarms and casts, and obtained 180lbs. of clear honey, after leaving the same number of hives that he began with, well provided for the winter. I have, however, heard of no success equal to this.

My first swarm was on the 5th of June, and this I was obliged to feed considerably. It had 18lbs. 5oz. of contents on the 1st of October. The others did not issue till a fortnight after this; and one, a large one, was hived on the 6th of July, which collected quite as much as that which came off a month earlier. In many instances, I have understood, that the late swarms did better than the early ones; and this, no doubt, was owing to the unfavourable weather in June, at the end of which month many hives were lighter than at the beginning. My hives gained in weight about the middle of May; for I find that the hive that swarmed first collected 1lb. 4oz. on the 17th of that month. There was no real working weather after this till the 3rd of July, when they began to gain immensely. A hive, belonging to a friend of mine, collected 6lbs. 9oz. on that day.

I put one swarm in the place of the parent stock, according to the "Country Curate's" directions. This weighed 5lbs. 7oz. in the evening. I was, however, surprised to find, that scarcely a bee left the parent-hive until the third day after removal; and I should be glad if he would inform me, and one or two others, who take in *THE COTTAGE GARDENER*, and have tried the experiment with a similar result, if this is always the case; as, if so, the swarm is not likely to be much strengthened when it issues late in the day. In one of my hives which did not swarm, I found, at the end of the season, two queens, and a large quantity of brood. I knew the queen to be three years old; and this, therefore, is a proof that they renew their queens when necessary; in which case the natural animosity that exists is suppressed. I saw a more striking instance of this in an observatory hive, where two queens lived amicably together for three or four months, both being fruitful during part of the time; and the old queen expired early in the year.

I should be glad to know if the "Country Curate" has an observatory hive; and, if so, how he contrives to keep it during the winter. I have one in my sitting-room (where I have a fire daily), which is now in a very healthy condition, and well-populated. I helped to swell the population by placing a quantity of brood on the top of the hive in September, which the bees gladly nursed, and as they removed honey which I gave them into the box and added fresh comb, I have allowed it to remain, and it will, no doubt, greatly add to their comfort and prosperity.—OBSERVER.

DISEASES OF POULTRY.

INFLAMMATION OF THE EGG PASSAGE.

[Although the following case terminated fatally, yet, if the judicious treatment had been adopted earlier, the result, probably, would have been different. At all events, even failures act as warnings.]

HAVING at the present time a favourite Cochin hen affected with inflammation of the egg passage (at least as far as I can judge from the symptoms), and being desirous of restoring her, I shall be pleased to know if any better mode of treatment could be recommended than the following.

In the first place I will state, perceiving the hen unusually dull on Saturday morning, led me to examine her with a view of ascertaining the cause, when I found the egg bag much distended; so much so, that I was led to suppose at first she could not pass the egg. I at once put her into a warm bath, immersing her for about ten minutes up to the under part of the wings; after which I made another examination, and finding that instead of the bag containing the egg as I at first supposed, it had become distended and very hard. I then gave her a dose of castor oil, which cleared the bowels freely. At night I administered one grain of calomel, and one-eighth grain of tartar emetic, made into a pill with linseed powder, which, with the warm bath, has been repeated every night. This evening I find the part much softer, and the hen appears rather more cheerful. I intend repeating the pill and warm bath. In your next, I will report again as to my success, or otherwise; in the mean time, I shall be pleased to have some person's opinion who has had more experience in such matters; should the treatment mentioned prove serviceable to others, I shall not regret having communicated it.—A SUBSCRIBER.

[I do not think that any much better mode of treatment could be adopted than that above indicated; it would, however, have been more in accordance with ordinary treatment, if the dose of castor oil had been given after, instead of before the calomel and antimony, as in that case the increased secretions caused by these medicines would have been carried off by the aperient. I should think the warm bath advantageous if given without exciting the hen, and care afterwards taken to keep her very warm.—W. T. TEGETNEIR.]

As the Cochin hen died this afternoon, I considered it would be as well to furnish you with a few more particulars for the guidance of your friend. On Thursday I omitted the bath, and as the bowels were irritated, and secretions less healthy, gave calomel one grain, antim. tart. one-twelfth grain, confection of opium sufficient to form a pill. Yesterday the bowels were less irritated; gave hydr. cum creta three grains, rhubarb three grains, compound powder of cinnamon two grains, formed into a pill with crumbs of bread. This morning perceived that the hen was sinking, and a few more hours would close the scene. A few hours after the hen died. I made a careful examination of her; found the oviduct much inflamed and thickened, and of cartilaginous appearance; the whole of the viscera with that exception was quite healthy. I will add, there was plenty of gravel and a manure heap in the yard, to which the fowl have free access.—A SUBSCRIBER.

[I do not think that anything could have been better than the treatment adopted throughout this case; and had the disease been one of acute recent inflammation, there would have been every probability of a successful termination. The cartilaginous thickening of the oviduct appears to have arisen from long-continued chronic inflammation, which, in an advanced state, I should regard as incurable. It would be interesting to know how long the hen had ceased to lay, as that might afford some clue to the period at which the disease commenced, and also whether she was a great layer. As a hen had been lost previously from the same cause, one might almost imagine that there must be peculiar reason for the disease. May it have been over-stimulating food? or the over production of eggs? or want of rest for the oviduct, from the hen's not being allowed to sit?—W. P. T.]

PROFIT FROM WILD FLOWERS.

A FRIEND of mine, whilst staying for the benefit of his health in the Isle of Wight, met with a poor and thriftless family, consisting of a man, his wife, and three children. Judging that the best way of helping them was to teach them to help themselves, he selected one of the little girls, and instructed her by means of two or three lessons in a superior mode of preparing and exhibiting sea-weeds. The project took; sales of them were easily made, and this new employment soon raised the family from a state of indigence to one of comparative comfort. Now, what can be effected with sea-weeds may be accomplished with wild flowers. There are many poor families who, if they could be put into a method of selecting and arranging bouquets tastefully, might find a ready sale for them. Whether as botanical specimens, or for simple nosegays, wild flowers are not turned to the account they might be; they merit greater notice, and a more extended appropriation.—S. P., *Rushmere*.

TO CORRESPONDENTS.

** We request that no one will write to the departmental writers of THE COTTAGE GARDENER. It gives them unjustifiable trouble and expense. All communications should be addressed "To the Editor of the Cottage Gardener, 2, Amen Corner, Paternoster Row, London."

TO PREVENT A HEN SITTING.—J. N. says—"In reply to 'K.' No. 217, the plan I have adopted lately, has been to confine the fowls wanting to sit under a rip for six or seven days, and feeding them *sotely* with the commonest boiled rice (1½d. per pound I give), with plenty of clean water. This I have invariably found to purge the fowls, and prevent wanting to sit. I named this plan, several months ago, to J. H. Payne, Esq.; perhaps he would tell you how it has answered with his fowls, if he has tried it."

ICE (J. W.).—Thank you; the promise was overlooked altogether. "All the details of the same (ice), up to placing iced things on the table," was volunteered; and when people make hasty promises, they must either fulfil them, or repent at their leisure. If you get up a strong opposition to the introduction of foreign ice, by collecting all our home stock into stacks or icebergs, and thatch them well, we shall tell how the "things" are to be iced and sent to table when the weather turns warmer. The ice keeps well in the Lowestoft and Yarmouths depôts; but no plan is so economical as the icestacks, *alias* icebergs.

NORTH GREENHOUSE (A Dabbler).—The recess between the buildings will do capitally to keep flower-garden plants in during the winter, if you can enclose it with glass, and provide against *damp* and frost. The north-east aspect is as good as any other for plants at rest, if they have sufficient light, dry atmosphere, and exemption from frost. Many of the showy summer plants would do very well in such a place, all the time they would be in bloom; but it could not be made a house for *growing* plants in. A work is preparing relative to "the points" of which you enquire.

FLOWER BASKETS (M. Fermanagh).—We are not sure that we understand your meaning. You say—"I want information about *making*, *arranging*, and *planting* flowers in baskets." But we shall keep your letter, and think the matter over. We have hardly any right to call our neighbour's attempt at flower-basketing stupid. If he is satisfied, that is quite enough. We shall give a few examples of how the things are generally done. The seeds of *Gaura Lyndheimeri* would, indeed, be most desirable; but we fear, now that notice has been taken of the plant, it will be too valuable in the trade to let it out by seeds. Nurserymen tell us that they never find stock enough of any new plant we recommend on our own responsibility.

EDWARDSIA GRANDIFLORA.—N. S. H. says—"A fine specimen, growing on the south wall of the Botanic Garden, Bury St. Edmunds, has produced a number of perfect seeds for the first time, although the tree has been planted upwards of fifteen years. Is this an unusual or rare occurrence in other localities?" It is, indeed, very rare for the *Edwardsia grandiflora* to ripen seeds in England, unless it be on the south coast. We never recollect seeing either it, or *E. microphylla* bearing seeds out-of-doors; but this notice will be sure to cause an inquiry as to how far we are right.

BULBS (S. S. S.).—Yes; oblige us by sending the hardy ones, and the stove bulbs also, and we shall treat of them all as they occur. We shall continue to point out those best adapted for pot-culture, and also selections from those genera having many species. Although these bulbs are called half-hardy, some of them are much more hardy than many of the hardy bulbs. *Amaryllis*, *Brunsvigia*, and *Alstromeria*, furnish examples of kinds much harder than many of the *Narcissus*, and even *Crocus* genera, as you shall see when we come to them. Pray make every suggestion you think of; you are entitled to have them attended to.

CLIANTHUS PUNICEUS (A Constant Reader).—"Should the almost bursting buds of one on a N.E. wall be picked off, or any protection given, and how? It is large, and has survived two winters."—It would be safe practice to cut off all the young recent growth, as well as the "bursting buds," and to cover with a double mat, or some equivalent, after the first frost of six or seven degrees. We have seen a nine-year old plant of it, and as large as a moderate peach-tree, killed outright with 20° of frost, although covered with two folds of mat, and against a south wall.

MIXTURE OF LILIES (Twelvemonth's Subscriber).—We very much

approve of your planting two circular beds with a mixture of *Lilium lancifolium* (red and white) and scarlet Martagon, with *L. longifolium* round the outside. See that the bottom of the bed is dry by good draining; and let *L. longifolium* have a little tan, coal ashes, or leaf mould over it in winter. These bulbs flowering at different seasons is not very objectionable, as their growth and leaves are so similar.

RABBITS (Bob).—We do not know of any separate work on Rabbits.

OAT-STRAW FOR COWS (J. B. H.).—We can state positively that oat-straw does *not* "diminish the milk of cows more than does the straw of either barley or wheat." Cut into chaff, and mixed with sliced mangold, sliced cabbage, or steamed potatoes, it makes an excellent fodder for them.

M. NEES VON ESSENBECK (Queen Mab).—You will have seen a notice of the party to whom you may forward your benevolent contribution.

BOOKS (F. B.).—Loudon's Encyclopædia of Gardening, and The Cottage Gardeners' Dictionary, are quite sufficient for you.

POTATO MURRAIN (A Casual Reader).—You invited our request; your postponement is discreet.

TURNIPS FOR COWS (Amateur).—It is difficult to say how many you should buy for the food of your two cows from this time until the 1st of May; we do not know their size, breed, nor appetite! However, it is a general rule that a cow requires daily in food three per cent. of her weight, so you can calculate how much to give each in addition to the grains and chaff you allow them. We should think 20 lbs. of chaff and grains, mixed in equal proportions, and 15 lbs. of sliced turnips, an ample allowance for a cow.

PEARS ON QUINCE STOCKS (A Constant Reader).—With us the Pears bloom profusely, but so early, that for the most part they are destroyed by the early frosts. By due protection this might be prevented.

TO PREVENT A HEN SITTING.—A Constant Reader says—"I have been recommended, and have tried the plan, with success, of keeping the hen in a separate house, without food, for three days. This, I believe, will always have the desired effect."

VEGETABLE OYSTER (Rev. C. A. L'Oste).—We do not know a plant so called. The roots of Salsafy, properly dressed, by boiling, mashing, forming into cakes, and frying in butter, have the flavour of Oyster patties. The *Pulmonaria maritima* is called "the Oyster Plant," its flavour being unpleasantly resembling that of the Oyster.

UNDER TENANT (J. S. W.).—You must consult some respectable attorney; no one could give an opinion without a personal interview and explanations.

FENCING FOR POULTRY YARD (Quærcus).—Galvanised iron wire is the best, and three feet high enough to keep within it your Shanghaes. Speckled Hamburgs and Bantams will require it to be twice that height. Your poultry-house is good, but we have our roof thatched *inside*, by a thick layer of straw confined by laths close to the slates. Warmth is most needed—you can always ventilate enough.

POINTS IN SHANGHAI FOWLS.—T. A. says—"Having just read Mr. B. P. Brent's observations on Shanghai or Cochinchina fowls with much interest, I must beg to mention that the most striking features in 'Shanghaes' are their great depth of breast, and length and size of thigh (not drumstick); in fact, that they more resemble turkeys than any other fowl yet known in this country. Good breasts and thighs are undoubtedly qualifications of the first importance, as *there* the meats (brown and white) are to be found *both excellent and abundant* in this breed when properly fattened. Colour is no criterion as to the purity of the breed, except that there are no black or pure white *thorough-bred* 'Shanghaes' in England. I quite agree that the dark birds are the finest, and have almost invariably found that the light-coloured birds are the smallest."

BEES: DESTROYING ROYAL CELLS.—Investigator says—"I am much obliged to 'Mary' for the reference to the 'Shilling Bee-book.' I remembered the passage soon after I had written the letter, and wondered I had forgotten it, as I nearly know the little book by memory, and there can scarcely be a practical difficulty which it does not meet. To insure the destruction of *all* the royal cells, it is necessary to take out each comb on its separate bar, for, though usually on the edges of the combs, I found one or two suspended within those narrow passages, near the centre of the combs, which serve as communications through the hive. I followed the directions at pages 17 and 38 of the 'Shilling Bee-book;' and will add a few hints, which may be useful to a novice. In the first place, do not be discouraged by an imaginary difficulty; I know more than one lady who has successfully performed the operation. Place the swarm on the stock's stand, and carry the stock some distance into the shade. Your assistant must blow a puff of smoke between each comb before you detach it from the sides of the hive. Commence at one side, and take up bar after bar; before replacing one, take up the next, till you reach the centre, and then commence from the other side. I cut out ten royal cells, three of which were ceiled over, and the others contained larvae in various stages. The bees were indignant at the frustration of their design, and immediately commenced the reconstruction of royal cells; but the queen obeyed my wishes, and so the cells did not advance."

ERRORS.—C. R. R. says—"There are three very sad mistakes in your notice in THE COTTAGE GARDENER of Dec. 2, in my report of the Country Curate's bee system, no doubt attributable to my horrid writing. In lines 28 and 29 you have it, 'and the bees, about 3 lbs., filled a dinner tumbler of the ordinary size;' this should be, 'and the bees about *three parts filled* a dinner tumbler of the ordinary size.' In line 41 you have it, 'one weighs, empty, 3 lbs., another 7 lbs., the third 9 lbs.;' this should be, 'one weighs, empty, 6 lbs., another 7 lbs., the third 9 lbs.' In line 55 you have it, 'with the cap in;' this should be, 'with the cap on.'"

ERRORS.—At page 187, col. 2, line 22 from the bottom, for "all," read "not;" page 188, col. 3, line 2 from the top, for "one," read "our;" line 15 from the bottom, for "judicious," read "judicial."

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last twenty-five years, the average highest and lowest temperatures of these days are 42.6° and 31° respectively. The greatest heat, 58°, occurred on the 25th in 1827; and the lowest cold, 10°, on the 24th in 1830. During the period 113 days were fine, and on 62 rain fell.

BRITISH WILD FLOWERS.

POPPY-WORTS.—PAPAVERACEÆ.

PAPAVER. POPPY.

Section I.—*Poppies with bristly capsules.*

(Continued from page 195.)

PAPAVER NUDICAULE: Naked-stalked prickly-headed Poppy.

Description.—This is a perennial. Roots fibrous, slender, and whitish. Stem none. Root-leaves numerous, on long

stalks, bristly, the lowest being the broadest and shortest, least deeply divided, and into the fewest and broadest segments; milky-green, especially on the under-side. From among these leaves arises usually a single, naked, cylindrical flower-stalk, but sometimes two such stalks, less than a foot high, rather milky-green, clothed with horizontal bristles, and crowned with a single pale yellow flower. Calyx of two oval, concave sepals, clothed with brown hairs; of the four petals, which are roundish, the two inner are rather the smaller. Stamens very numerous, having yellowish filaments, and broadish, flattened and channeled anthers. Germen roundish, greenish, crowned with an eight rayed stigma. Capsule, or seed-vessel, roundish, oblong, and bristly. Seeds black when ripe.

Place where found.—Gathered by Professor Giesecke, of Dublin, among rocky glens in the hills at Achilhead, on the north-west coast of Ireland.

Time of flowering.—June.

History.—Being hitherto found upon only one spot in the British Isles, it must be considered as among the many plants of which it may be questioned whether they are really natives. At all events, it was cultivated here as long ago as 1730, for seeds of it were sent to the Eltham Garden in that year, by J. H. de Sprekelsen, who had it from the province of Argunsky, in Siberia. Its flowers are as sweet-smelling as the Jonquil, emitting their fragrance especially during the cool of the morning and evening. Sir W. Hooker, and Dr. Lindley, have enrolled it in their catalogues of our native plants. Linnæus doubted whether it is not a variety of *Papaver alpinum*, or Alpine prickly-headed Poppy. Being a native in great abundance of the shores and islands of the colder regions of North America, a seed may have floated to the coast of Ireland. (Martyn. Withering. Hooker.)

THE most wonderful and most gratifying botanical discovery since the demonstration of the sexuality and circulation of the sap in plants, is the fact that Wheat, at present known to botanists as *Triticum*, is only the miserable grass, *Egilops ovata*, improved by cultivation. We noticed this discovery very briefly at page 267 of our last volume, and we recur to it now, in consequence of the lecture and exhibition of specimens of the plant in the course of its transformation, at the Meeting of the London Horticultural Society on the 7th instant.

The Society having announced that something would be seen and said on the subject at this Meeting, a larger number of the members were attracted to the meeting than is usual at this season. The cultivators of the science of botany, and of practical gardening, were there also in greater numbers than usual; and no wonder, seeing that this discovery relates to a circumstance most remarkably connected with either of their departments.

No one has ever discovered the native country of Wheat, Barley, Rye, or Oats; yet, if a year ago we had

suggested that these at the beginning of the world were not created as we have them; or even if we had said that these improvements of wild produce are merciful sweeteners and aids to that toil by which man is ordained to eat bread by the sweat of his brow, we should have been suspected of being disciples of the author of "Vestiges of the Creation." Nevertheless, the opinion has been gaining ground for years, that in the vegetable, and even animal life, the types originally created were very much fewer than the forms now existing seemingly in a state of nature.

It was in order to exemplify part of this question, that the Society were this day prepared with proofs to show the successive stages of development of that wiry, small grass, *Egilops ovata*, a native of the South of Europe, from the wild state, to the full-eared Wheat of the Pharaohs of Egypt, or of the farmers of old England; and, as if on purpose to overthrow the idle theory of the return of improved races to the original types if left to nature, we have the discovery by Col. Chesney, of Wheat and Barley on the banks of the Euphrates,

the remains of cultivation from the days of Jonah, while the whole circle of the history of plants does not furnish a single well-authenticated instance of an improved variety or species, either by chance or design, turning back to the original variety or species from which it sprang. Yet the doctrine of reversion, or disimprovement, is an axiom in the creed of some who bear the weightiest names among living physiologists. Our double Daisies, Chrysanthemums, and China Asters, our double Ranunculuses, Larkspurs, Pinks, Cloves, and Carnations; nay, all our cultivated Flowers, Fruits, and culinary Vegetables, have been improved by exactly the same process as that by which M. Fabre converted an insignificant grass, by seeds, in twelve successive generations, into a true Wheat plant, the most important of all the cereals, and that, too, in the face of, and against, the mature evidence of botanical science; for, by common consent, the Wheat was placed in a widely different genus from that of *Ægilops*. It now appears that the two are not, even specifically, distinct, but only in different degrees of development.

One of the forms of this species (*Ægilops*) was observed by M. Fabre to have a tendency to assume a different form and character under particular circumstances, and this tendency, in a more or less degree, is seen in a vast variety of plants under cultivation, but the cause of it is an entire mystery. It is a quality, a power, given to those plants by God—we see and we benefit by the effects—we can discover the means of setting that power in motion which will produce those effects—but we can lift the veil no higher. We can go on, however, tracing those effects, and we can find that when improvement once appears in a form of the species that is barren, we have no farther means of encouraging it to greater development, but we can retain it just as it is, by extension from cuttings, and we call it “a sport.” On the other hand, if the new form is capable of bearing seeds, we know that in the first two or three generations of seedlings, provided they are not affected by foreign pollen, many of them will turn back to the original species, some of them will be only repetitions of the first departure, and a small number will often show a still greater departure from the first species, or type. Here is the point, then, where we want skilful observers, like M. Fabre, to step in and follow out the tendency, by patient industry, to its ultimate limit, or to any stage of it which we think the most deserving.

This is just what M. Fabre has effected with the *Ægilops*; and although the result of his experiments will surprise everyone, there is nothing new in the whole process, nor anything at all which is not familiar to every gardener. The last improvement in the flower of the Dahlia was obtained by the very means which M. Fabre used in producing the Wheat plant from a worthless grass. This, so far from being a disparagement, renders the discovery of universal importance, for it cannot fail to stimulate others, in different countries and climes, to trace out, still further and fully, a law which the Creator of all has stamped on the vegetable kingdom, for the use and gratification of His creatures.

Here let us pause to raise a warning against two errors, one of which is prevalent already. In the first place, let it be remembered that the wild grass has not been changed into wheat by a process like changing wheat into flour, or flour into bread. To entertain such an opinion would be a dangerous and fatal error. So far from such being the case, the end was obtained by merely following out that which is well understood as a law of all organised creatures. Secondly—let it be remembered, that seedlings from a natural sport will revert to the first parent before the nature of the sport is indelibly fixed by successive generations, is a fact which has never been denied. Every grower of seedlings knows this; but it does not support the doctrine of the reversion of seedlings obtained by cross impregnation; the assertion of such reversion is altogether false and groundless. Let a true cross be obtained from parents distinct in species, and then, if their progeny produces seeds even to endless generations, no one of the seedlings will ever appear the exact image of either of the two first parents.

The lecture on the discovery of M. Fabre, before the Horticultural Society, was listened to with intense interest, and it was delivered by the lecturer whilst holding up a beautiful drawing, representing an ear of the plant from every stage of the experiment. Beginning on the left-hand-side of the drawing, an ear of the original grass, *Ægilops ovata*, was represented; the next ear was the sport, which is called *triticoïdes*, that is, wheat-like—but the likeness to wheat is very faint indeed. The first seedling from *triticoïdes*, was the third ear in the drawing; and the fourth ear was from the second generation. Ears two, three, and four, looked very much alike, at the distance where we sat; all we could see was that three was somewhat longer than two, and four longer than three; the fifth ear shewed the attainment of a wide difference. It was said to be like a species which grows wild in Egypt, and round the eastern borders of the Mediterranean, and is called *squarrosa*, or rough-spiked—rough and bristly it certainly was—and so on they went, in a row, ear after ear, up to the true wheat-ear itself.

From the lecture we learned that M. Fabre is a gentleman skilful in many things; that his truthfulness is undoubted; and that his word would be readily accepted by all who know him; that his experiments were not carried on in a corner, but out in the open fields, after the manner of a large farmer; that his own men and his neighbours saw all he did, and helped him to do it; that he began in 1840, and that in the twelfth generation, this last summer, the “Wheat itself stood revealed.”—B. J.

COVENT GARDEN.

If any evidence were required confirmatory of our opinion as to the possibility of an extensive cultivation of the more choice varieties of fruits for the supply of our markets than at present exists, it might have been found on Tuesday last, at the meeting of the Horticul-

tural Society. From various parts of the country there were some very fine specimens of the best late Pears exhibited, and among these some from our excellent coadjutor, Mr. Errington, who, if we mistake not, resides in a district which is not remarkable either for the superiority of its soil or climate; but still he was enabled to compete with those who are more highly favoured. We hope we shall live to see the day when such varieties as *Glout Morceau*, *Passe Colmar*, *Ne Plus Meuris*, and *Beurré de Rance*, will be offered in Covent Garden Market during the winter and spring months, in quantities as great as the *Lammas*, *Williams' Bon Chretien*, and *Bergamots* are during the early autumn. There is no reason why it should not be so, if commercial growers could only be brought to see what their own interest is. The greatest London market-gardeners have long found out the value of such crops, and it is by them that the market and fruiterers are mainly supplied; but the country orchardists are wholly ignorant of, or perfectly easy on the subject. We do hope they will bestir themselves in this matter, and thereby benefit themselves and the public also.

We had not space last week to finish our remarks on the selection of Pears, and consequently resume the subject.

13. *Hacon's Incomparable*.—A very excellent and hardy Pear, which is in use during December and January. It is of good size, and the flesh is buttery and melting, with a rich, sugary, and vinous flavour, and highly perfumed.

14. *Broompark*.—This is one of the finest varieties raised by Mr. Knight. It is particularly rich and highly-flavoured, and the tree is very hardy. It is not as yet in general cultivation, but we can strongly recommend it as one of the very best winter Pears. It ripens in January.

15. *Nelis d'Hiver*.—If we grew only six Pears, this would be one of them. It is certainly one of the richest of all our winter varieties. The tree is not, from its natural habit, adapted for orchard planting, and must, therefore, be grafted standard high on some strong growing sort. The fruit, although of larger size from an espalier than from a standard, is, nevertheless, equally as rich in flavour, and attains as high a degree of perfection when grown on the latter. It ripens in December, and continues in use till February.

16. *Shobden Court*.—This is but very little known; but being very hardy, and succeeding well as a standard, it ought to receive a greater extent of cultivation than it at present has. It is a very first-rate variety, of an exceedingly rich flavour, and is at maturity during the months of January and February.

17. *Ne Plus Meuris*.—This would, in our estimation, be another of six. It is one of the very best late Pears, and is at this season, along with *Nelis d'Hiver*, the most highly esteemed of any in the market. It is very richly flavoured, and is in use from December till March.

18. *Easter Beurré*.—This is a fine, large, and handsome fruit, which was introduced, not very many years ago, by the Horticultural Society, from Belgium. It is

of first-rate quality, fine-grained, buttery, and richly-flavoured. It is in use from January till March.

19. *March Bergamot*.—This is another of those hardy and richly-flavoured varieties, for which we are indebted to the industry of Mr. Knight, the late President of the Horticultural Society, and one which ought to be in all collections. We all know how difficult it is to obtain very late Pears of the best quality, and how few there are which keep till the spring months; it is, therefore, with much gratitude that we hear of anything which will fill the void which is too apt to be felt at this season. We know of none better adapted for this end than the *March Bergamot* and the following variety. This *Bergamot* is a medium sized fruit, of an exceedingly rich flavour, and as it is very hardy, it will be found an excellent variety for general planting. It is in use during March and April.

20. *Beurré de Rance*.—We do not exaggerate when we say that this is, perhaps, the most valuable Pear we have, for it is in use at a season when all others are gone. There are, it is true, some new varieties lately introduced, which purport to be as late, and even later; but before we have given these a fair trial, and have had as much experience of them as we have of *Beurré de Rance*, we must, in the meantime, give this the palm. It is a very rich, melting, and deliciously-flavoured Pear, and is in use from March till May.

We have thus given a list of twenty of the best dessert Pears we consider suitable for the purpose we have been treating of; we shall now, by way of variety, furnish the remaining four, as the best adapted for culinary use.

21. *Vicar of Winkfield*.—A very large and handsome fruit, which, when grown against a wall with a south or west exposure, is melting, and well-flavoured; but when grown as a standard forms one of the finest stewing Pears we know. Its great size and fine-grained flesh are great recommendations to it. It is in use from November till January.

22. *Bellissime d'Hiver*.—Another large, handsome, fine-grained fruit, far superior to the *Catellar*, or any of the old varieties. It is in use from November till April.

23. *Bon Chretien d'Hiver*.—One of the most highly esteemed of the old French dessert Pears among the old gardeners both of this country and the continent. To have it at maturity it requires a wall, even in a good situation; but if grown as a standard, the fruit is admirably adapted for *compôtes*. In cooking it becomes very tender and fine-grained, and its juice becomes a syrup, which contains a perfume and natural sugar, which cannot be communicated artificially. It is in use from December till March.

24. *Franc Réal d'Hiver*.—Another very excellent stewing Pear, which before cooking is coarse and husky, but very juicy and aromatic; but when stewed becomes tender and of a fine bright light purple colour. It is in use from January till March.

We shall conclude our remarks on this subject by just calling the attention of our readers to one or two other fruits, which may be advantageously and profitably planted in such situations; we mean the *Damson* and

Medlar. Of the former, the two varieties which are generally cultivated are the *Common Small Black*, and the *Shropshire* or *Prune Damson*; the latter is the larger. Of *Medlars*, there are also several varieties, but those generally grown are the *Dutch* and *Nottingham*; the former is the larger, but we prefer the latter for flavour.

The Market during the week has begun to assume much of a Christmas aspect; and the traveller might imagine himself traversing some forest on the Norwegian Alps, from the immense quantity of Spruce Firs which are standing about in all directions. These, to form "Christmas-trees" for the amusement of juveniles during the coming holidays, will be in great requisition. There is, generally, an air of gaiety pervading the whole; but as this will be considerably developed during the week that is to come, we shall reserve our review of this part of it for our next report. As our notice of fruits has this week extended considerably longer than we anticipated, we shall leave till next week any observations we would have made on this occasion, particularly as all that would have been worthy of comment will be displayed in tenfold importance during that which is to come.

H.

GOSSIP.

A CORRESPONDENT at Birmingham writes to us as follows, concerning *Garden Scrapers* :—

"You have given drawings and descriptions of garden scrapers, which are in some respects desirable, but expensive. They are expensive, because the making involves employing the blacksmith. I enclose a drawing of a scraper made in one piece of cast iron, which in my opinion has many advantages. In the first place, it is cheaper than any wrought iron article can possibly be; it is very light; is ornamental; fixes with the greatest ease, and remains firm in the same place in my garden (a light soil) as long as I please. I obtained mine (and I have a good number) from Messrs. Thomas Jones and Sons, Ironfounders, Bradford-street, Birmingham. They are two shillings each, or eighteen shillings a dozen."

Breadth of scraper to admit the foot, $7\frac{1}{2}$ inches; breadth of the fang penetrating the ground, at the top, $3\frac{1}{2}$ inches; length of the fang 15 inches; entire length from the top of the ornamental knob to the point of the fang, 22 inches.

The following suggestion from the Secretary of a distant Horticultural Society is well worthy of atten-

tion; though we must decline the honour of the judgeship—

"Your useful publication being weekly spread over the whole of Britain, amongst hundreds of floral amateurs, could it not be made the means of bringing them into direct competition, no matter from what part of the country, now that postage is so cheap?"

"The way I would propose is this: Fix upon some flower which could be packed into a small compass, and which could pass cheaply through the post-office. Take, for instance, that popular flower the *Pansy*. Name a day on which the competition is to take place. Supposing that you were to be the judge, then give notice, through means of your Journal, that all flowers must be posted so as to be delivered to you at a certain time; and through the medium of your Journal you could publish the result, together with any remark on new or remarkable flowers which might be submitted for competition. Thus might be brought into direct competition the amateur of all parts of the country. I, myself, who live on the borders of Scotland, nearly 350 miles north of you, might compete with the amateur of Kent or Devonshire. Yorkshire, Cumberland, Norfolk, Essex, and the counties of Wales, might send forth competitors. As for prizes, I think they would not be required, the honour of ranking high would be sufficient."

The following is a list of the *Poultry Shows* of which we are at present aware. We shall be obliged by any of our readers sending us additions to the list, and giving the address of the Secretaries.

CORNWALL (PENZANCE), January 10th, and 11th. (*Secs.* Rev. W. W. Wingfield, Gulval Vicarage, and E. H. Rodd, Esq.)

HONITON, January 12th. (*Sec.* H. K. Venn.)

GREAT METROPOLITAN, January 1st, 3rd, 4th, and 5th.

RENOVATION OF FRUIT-TREES.

(Continued from page 180)

We will now conclude this subject by taking the six classes consecutively—

1st. AGED TREES.—The treatment of trees which are simply wearing-out is simple indeed; they want "more corn and less whip," to use a groom-like phrase. Such trees as we find them, under ordinary treatment, whether in orchards or kitchen-gardens, have been neglected for a length of time as to root-culture, manurings, &c., whilst surrounded, perhaps, by young, gross, and rampant neighbours, which have battened at the expense of these "good old has-beens." But it often fares with fruit-trees as with men: no longer pipe, no longer dance. However, folks are sometimes wrong about the "piping;" we have seen thousands of hardish-worn fruit-trees, in our day, which would have returned a much greater per centage of profit (had they received timely assistance,) than young and rampant trees, which, in the splendid exuberance of their shoots, only flatter to betray. People get impatient too speedily about these wearing trees; still they do well to think of providing successors, for such is the established order of things.

To come to the point: the soil throughout the roots and fibres of old-bearing and wearing-out trees becomes completely exhausted; no man can give it the texture it originally possessed, or add more quality, unless through the medium of surface-dressings, liquid-manure, or a compost of a most coaxing character applied to the extremities of the roots. The two most steady and enduring plans are—surface-dressing, and culture at the extremities, accompanied by a heavier pruning in the branches. Liquid-manure, although

very useful, is more fitting, perhaps, as a summer application, especially at what is termed stoning-time, when fruit are apt to be cast with temporary droughts. For general purposes, use a compost composed of equal parts sound loam and rotten manure, well blended, whether for the extremities or the surface. In laying it on—and it may be six inches in thickness—let every portion of loose soil be scraped away from the surface, even working down a few inches occasionally between the roots. This is done in the rest-season, say November or December; and before applying the dressing, use a few buckets of rich dunghill-drainings over the surface; such cannot be too strong at this season, and when this has settled, apply the casing of soil, and avoid treading over it until settled and dry: the pruning should have been done previously. In adding to the extreme points, of course the operator must throw out a trench at the extremities and fill it up with fresh compost. In pruning aged trees, let most of the small, inferior spray, closed in the interior, be pruned away, maintaining the prime leaders to the last, unless diseased; for from these channels will the most fruitful wood be produced, especially after inferior or choked spray has been removed. In addition to pruning, we would scrub the bark all over with a coarse brush, using some stable-drainings, with plenty of quick-lime blended—thick as mud; indeed, it will be well to thicken it with clay. Now, it is but fair to observe, that we have never used the latter mixture precisely, but we have much faith in it. We were informed, a while ago, by a Cheshire rector, who is “well-up” in everything relating to gardening affairs, that Dr. Darwin, of Shrewsbury, had found the stable sewage the best cleanser of the bark of trees, and that they wonderfully improved in health on its application.

2nd. TREES WORN WITH BEARING.—It might seem at first sight that this, and the former case, are nearly identical; there is, however, sufficient difference to require pointing out. A tree may be worn with bearing before it is seven years old, but it cannot be aged. It may be exhausted in a temporary way, and perfectly capable of rallying in a year or so; but the aged tree can scarcely be said to rally, although it may prove of immense service for many years by generous treatment. There is not occasion, in this case, to have recourse to the trench system at the extreme points; something of speedy action is best, and liquid-manure may be had recourse to, with a rich top-dressing; to this may be added a somewhat sharp amount of pruning, in order to limit the bearing powers of the tree for a season.

3rd. DISEASED TREES.—Another distinct class occasionally; for a tree may be diseased, and yet in neither of the other classes, and may form a complicated case by a union with one or more of them. Now, as a knowledge of the disease is necessary, it becomes eminently essential to ascertain what it is, and its cause. Nearly all our fruit-tree diseases may be thrown into two broad classes, for which we beg to offer the following titles, viz., *Constitutional* and *Adventitious*; each of which may certainly comprise many cases. As instances of the constitutional, may be offered such as *canker, gum, decaying points, corroded bark, &c.*; and, as adventitious matters, *wounds and injuries of any kind, blights, or corruptions* of the system through *insects, frost injuries*, or those arising from a *too low temperature* during the growing season, &c. These may not be all, but they comprise the principal; and it is pretty evident, that the first class are by far the most difficult to overcome; as instance, the *canker* in apples, which no nostrum or recipe has yet been able to conquer, but which mere preventive methods may keep tolerably well at bay. One of the most important proceedings with trees not too old nor too large, is to take care that

the roots are furnished with a pure soil: a loam neither clayey nor sandy.

As this matter of *loam* appears so puzzling to many of our readers, we advise them in all cases of doubt to apply to a first-rate gardener, who, although he may not betake himself to chemical analysis, will yet tell correctly, in a few minutes, whether it be what is known as a general fruit-tree loam. People talk very learnedly about deleterious qualities supposed to exist in this soil or that; but this is, in the main, a mere bugbear. It is, for the most part, principally a matter of texture. Look at our nurserymen, the most knowing of them in such points, how often do they err in their choice of a loam? or, who hears them complaining about its chemical characters? Now, mere garden soil can never equal this loam; it is neither so rich in organic matter, nor so fresh, and it is this freshness, combined with excellency of texture, which renders a pure loam the fittest medium to recover or assist a diseased tree. In all difficult cases, we would plant or surround the tree roots with this loam in its simple state, and if it becomes necessary to impart extra vigour to the tree, let it be by rich surface dressings; and by an occasional application of liquid manure. Of course, in cases of canker, something may be done by scraping the parts clean, and binding in a dressing; we have found a mixture of cow dung, fine loam, and a little lime a good application. The adventitious diseases are too varied to be fully dealt with in a single chapter; and we may just point to the pruning-knife and patience as adjuncts in the case of defects consequent on the attack of insects, which sometimes cause distortions and perversions of the character of the tree. Wounds and injuries may be treated similarly to canker; and those arising from low temperature, by trying to enhance the warmth of the atmosphere by which they are immediately surrounded; to effect this, thin training, the removal of objects which impede the light, and on walls the use of liberal copings, &c.

RAMBLERS—Here is a case for the root-pruner, or the transplanter, we care little which. This much may be said—where any desire exists to renew the volume of the soil, transplanting is best, the tree not being too old or too large; and where there is no fault in the soil, root-pruning will be perfectly eligible. In addition, a liberal branch-pruning, thinning out, and shortening back freely.

SHY KINDS.—There are some kinds of fruits that are by nature shy, or, in other words, which do not grow freely; these, of course, must be treated in a more liberal way. Stimulants may be had recourse to, and surface-dressings every two years will be very useful, and the occasional application of liquid-manure during the growing season. A compost composed of one-part free loam, one-part rich manure, and one-part leaf mould, the two latter three-parts decomposed, and the whole thoroughly mixed, will be found an excellent application in this case. In general, this coating of some three to four inches will become filled with fine fibrous roots, which will infuse an amount of vigour in the tree hitherto unknown.

GROSS YOUNG TREES.—These are to be distinguished from the class “*Ramblers*,” notwithstanding they may be rambling young rogues. It was doubtless inferred by the reader, that the former class signified established trees which show an apparently invincible coarseness. We now speak of that gross fitfulness which is so frequently met with in young trees, not alone through a particular habit inherent, but more commonly through a too generous patron, who perhaps may be a “border maker”—a man of composts; and such men have frequently reminded us of those affectionate animals termed apes, which have been said to hug their young ones to

death in the most affectionate manner. "Save me from my friends; I can manage my enemies."

Well, then, to remove the midden is to get rid of the mushrooms, but it is not always convenient to remove this midden, or, in other words, to change the whole character of a costly border. What then? Why, transplant by all means, adopting instantly our platform mode, or station-making. Those who have not back numbers of THE COTTAGE GARDENER to refer to will do well to get our excellent little *Cottage Gardeners' Dictionary*, which should be in the hands of every one who, not being complete in gardening matters, and with whom time is precious, wants merely five minutes' advice, such as he can rely upon; there he will find these and other matters so highly simplified that "he who runs may read."

And thus we take leave of a subject about which much obscurity has existed in by-gone days; but which the advancing spirit of the age has scattered to the winds, or soon will do. Gardeners, however, must not only have reasons "plentiful as blackberries," but be prepared to offer them in a cheerful way, not as a mere accommodation, but as a duty.

Is it necessary to add, that this time of year is most propitious for laying down plans of renovation, and also for carrying them out in at least their first stages?

R. ERRINGTON.

MEETING OF THE HORTICULTURAL SOCIETY.—DECEMBER 7, 1852.

AFTER the lecture on the discovery of the origin of Wheat, the next object which seemed to command most attention was that about cutting-off the leaves of root-crops before the roots arrived at maturity, without prejudice to the weight of the crop, or to the quality of the root, as far as it has been yet practicable to ascertain; but this subject will be discussed more fully next week.

Among orchids exhibited there was, first, a splendid specimen of the true *Vanda suavis*, from the Messrs. Veitch, of Exeter, bearing about fifty full-blown flowers, showing how different and much better the true species is than the variety of it called *tricolor*, which has usurped its place in some of the best collections round London. Then *Limatodes rosea*, a beautiful new terrestrial species, exhibited in public for the first time. This genus is the nearest in affinity with *Calanthe*: the species exhibited is deciduous, and flowers, after resting, from the bottom of the pseudo-bulbs before the new leaves appear; the flower-stalks are from six to nine or ten inches high, covered with a short soft down, which extends along the footstalks of the individual flowers; the flowers are numerous, in terminal spikes, and opening first from below, as in the *Calanthe*; they are much about the size, or hardly so long, as the flowers of *Calanthe veratrifolia*, and are of the most delicate light rose-colour; altogether a charming plant. The pseudo-bulbs are clustered round and round, from two to three inches long, and closely furrowed with sharp angles like an *Echinocactus* without the spines, so that you could pick it out of a thousand species, at first sight, without seeing a flower or leaf; the leaves I did not see, but they are curiously set on the top of the bulbs by a joint, so that they all fall off at once when they are ripe, leaving a flat top to the bulb. The best way to manage it was read to us from a letter sent up with it. That letter recommends a generous, open compost, as for *Phaius*, *Calanthe*, and other ground orchids, encouraging a vigorous growth after the leaves are fully expanded; to cease watering as soon as they turn yellow; and to rest it like a stove bulb in a hot, dry place—or say, by turning the pot on one side on a high shelf in the orchid

house, there to remain until you see it move of its own accord, like an *Amaryllis*. It was sent from Moulmein, by Mr. Thomas Lobb. The genus was named by Blume, and the price is 63s. to 505s. according to size.

Cut flowers of *Zygopetalum Mackayi*, in varieties, and of a fine spike of *Cattleya guttata*, which made my heart ache to see it go without a handsome prize; but such is not awarded to cut flowers, and very properly too. Nothing of the gaudiness of the *Cattleyas* is inherited by this species; the lip is like that in *C. Forbesii*, and the rest greenish, with brown spots thickly dispersed all over the inside. Yet the specimen had a noble appearance, from the large number of flowers, twenty to thirty, set close on the top, exactly like the flower-head of a horse-chesnut. The next plant was the newest and the oldest plant in the room, *Malva umbellata*, a native of New Grenada, and growing there so high up in the mountains as to enable it to live out-of-doors with us through the summer. It was here once before, and lost; the last we heard of it was in 1822, when the lecturer had a beautiful specimen of it from the late Mr. Lambert, from the open air at Boyton, near Salisbury, where it flowered "all over" for a long time in the summer; it makes a dense spreading bush, and throws out its beautiful purplish flowers from the top of the branches like a Geranium. Very likely it cannot be bought before this time twelve-months; but it is well worth while making a memorandum of it. When it will come out, it will not run the circle of a new Geranium—be sold to-day at five times its worth, and the next at not one-third of its real value—as it is in the hands of the Horticultural Society, who will give it to all the nurserymen who are Fellows, when there is a stock of it.

Skimmia Japonica.—The same plant as I mentioned before, and, as I then said, it will be a standing dish with us till late in the spring; or, perhaps, I ought to say Standish's dish, for I think he will not be able to treat us to a better this winter. There is another *Skimmia* in the country, from the north of India, which is very like *Japonica* indeed; it is named *laureola* (laurel-like), because the leaves smell very strong, and like the sweet bay (*Laurus nobilis*). They have been raising a dust about these two beautiful plants, so to be certain, I went to Mr. Jackson's nursery, the evening before this meeting, to see *Skimmia laureola*, for I can almost always see anything new there at my leisure, and I find it is as strongly scented as possible, the leaf is also thinner than in *Japonica*. When I got to Regent-street, I tried *Japonica*, and there is no smell in the leaf, for I spoiled one of them by squeezing to make sure; and now Mr. Standish will know his plant was not hurt by carelessness, and I shall make up the damage.

Tropaeolum Lobbianum.—There were three beautiful nosegays, of three forms, of this useful winter-flowering plant, guarded with leaves of the rose-scented Geranium, sent by Mr. Ayres, of Blackheath. Two of the forms are quite new, and far superior to the species; one of them, called *Triomphe de Gand*, is three times larger than *Lobbianum*, and of a much better and brighter colour (crimson); the other is called *Hockerianum*, is as large as the last, a bright orange with a large crimson dash at the bottom of each of the five petals. He asks 2s. 6d. a plant for it, and it is well worth the money; every one who has a nice warm greenhouse should grow the three—no plants can be easier grown, and they flower profusely all through the winter, and run about like a hop all up the rafters, or trained against the back wall. Cuttings, rooted in the spring, and grown kindly through the summer, will come into bloom in November, and that is the best way to keep on with them; they hold on a long time as cut flowers in a room, and show as bright by candle-light as in the daytime.

Daphne indica rubra.—By far the largest specimen of this I ever saw was here in full bloom, in a square wooden box. I should think it was five feet through, and it looked like a second-sized specimen of the *Azalea indica* at a May show. It was sent by Mr. Edmunds, gardener to the Duke of Devonshire, Chiswick House.

Amaryllis reticulata.—A fine-grown plant, with two scapes, bearing four large reddish flowers each. I notice this to show how little some of the best gardeners in this country know about the names of bulbous plants, for it is really a hybrid *Hippeastrum*, worked from *H. aulicum*. It is quite excusable to call them *Amaryllis*, because the species were published as such before our knowledge of them was complete; but to confound any of the breed of *aulicum*, to the third or fourth generation, with *reticulatum*, or any of its crosses, as far as we know them, shows how little the affinity of bulbs is understood among us. I have not seen the true *reticulatum* these eighteen years, but I can give a sign by which a schoolboy could tell it at once from any of the 400 or 500 species belonging to the order, and also from the more than 4000 varieties into which they have branched out, and that sign is the large white eye at the bottom of the *perianth*, or flower leaves: there is not a single plant in the whole order with this conspicuous mark but itself. The hybrid bulb before us is from *aulicum*, or an early cross from it, by the pollen of *equestre*, or some of its early crosses; and here are the signs—*aulicum* has a large green eye and a smooth eyelid, or margin; *equestre* has the green eye in the form of a star, with a fringed eyelid. Now, the plant in question has a large green eye, not exactly as in *aulicum*, nor quite a star like *equestre*; it has a fringed eyelid, or partly fringed and partly notched: the sepals in *aulicum* are as stiff as wax, and upright; *equestre* has them wavy, and so has this hybrid, but in a less degree; the colour is just intermediate between the two.

There is a distinct class of dwarf Melastomads on the secondary ranges of hills in the East Indies, which are more herbaceous-like than the rest of the order; and they are easily known, from wanting the ribs on the leaves, which is one of the most characteristic features of Melastomads. Roxburgh is the best authority for them. We hardly know any of them in England; we have just got one of them in our Dictionary, an annual, and a second appeared at this meeting from the garden of the Society, and a charming little thing it is; you would take it to be a cross between some dwarf small-leaved *Begonia* and a rose-leaved *Melastoma*. They call it *Sonerila orbiculare*; it is just the sort of thing for an amateur; and although the very leaf of a Melastomad reminds us of a stove and damp atmosphere, the *Sonerilas* will do with the same treatment that suits *Begonias*, and they are just as easily increased. Make a memorandum of this also.

Brugmansia, or rather *Datura sanguinea*. When I first wrote about keeping all the Daturas out in the open ground, from year to year, I was met in more than one quarter with, "Don't you wish you may get it?" Well, we had beautiful blossoms up from Dorsetshire of the red *Datura*, that has been growing out-of-doors there ever since it was introduced, with hardly any protection at all; and if it is cut down, or any of them injured by frost, up they come next year like Fuchsias, and flower as abundantly. This I was told by the gentleman who sent them, the Hon. W. F. Strangways, who has always helped the Society to a knowledge of his half-hardy gardening. We had a whole tray full of cut flowers from the open ground at this meeting, some of which I told of last February, such as *Azara integrifolia*, *Lithospermum rosemarinifolia*, *Edwardsia macrocarpa* and *grandiflora*; this last ripened seed this autumn, at the Bury St. Edmund's botanic garden, on

the open wall. In addition, we had to-day the Spanish *Convolvulus cneorum*, with large white flowers; *Veronica Andersonii*, with lilacy-blue flowers in long round spikes; and one of the honey shrubs from the Cape, *Protea melifera*, with a beautiful flower-bud, shaped like a sharp-pointed cone, all from the open ground. Mr. Pince, of Exeter, sent two new conifers, one a young plant, looking like some glaucous African cypress, the other a sport from the *Chinese arbor-vitæ*, as it appeared to me, with a bluish shade, which, if it keeps true, will make a very distinct thing. From Plymouth, there were Lemons, from an open wall, in the garden of J. Lockyer, Esq., of South Wembury House, as fine-looking as any from abroad. From the garden of the Society we had a large collection of plants, besides the Bush Mallow, and *Sonerila*, such as winter-flowering Heaths, a large collection of *Chrysanthemums*, *Manettia bicolor*, *Triumph de gand Tropæolum*, and others, with one of the best winter-flowering plants belonging to the *Justicias* or *Justicia-looking* plants, with crimson-scarlet flowers, and the name of it made every face in the room smile. Those who hear themselves, night after night, abused, and called everything but senators, without moving a muscle, and even the lecturer himself, whose jaws seem as if made of cast-iron, could not resist the general twitter on his pronouncing the words, "*Sericographis Ghiesbreghtiana*." There was also a good specimen of *Camellia Donkelaeri*, and lots upon lots of the *Pomponé Chrysanthemums*, and a few of the old ones, but that class was lost "between two stools" this season.

I forget if I ever told that her Majesty Queen Victoria, and her Grace the Duchess of Sutherland, are two of the most keen competitors at these shows. There is no mistake about them; it is like diamond cut diamond to see her Grace beating her Majesty, and her Majesty beating the Duchess. The Queen was victorious this time by heavy odds, or full twelve ounces in a 7 lb. 8 oz. Pine Apple, of the smooth-leaved Cayenne, against a 6 lb. 12 oz. Providence. The gallant Colonel Baker, of Salisbury, entered the lists with a beautiful Cayenne Pine, 5 lb. 11 oz. There were several more fine-looking Pines, and the Grapes were excellent—the best Muscats from Mrs. Maubert, of Norwood, and the finest St. Peter's Grapes from Mr. Davis, of Oak Hill, near Barnet. Nothing could exceed the colour and bloom. But, of all the fruit, a splendid dish of the true old Golden Pippin, from Mr. Snow, attracted most notice. They were from an east wall, and the trees are as healthy as the Downton Pippin. D. BEATON.

THE INFLUENCE OF THE BEAUTIFUL.

"I know that there are many of the poor who possess fine feelings, and have a keen sense of the beautiful, but such feelings are suffered to rust out and die, because their possessors are too hard pressed to procure themselves any gratification. Else, why is it that we so often see the Geranium or Rose tree carefully nursed in an old, cracked tea-pot in the poorest room, or the *Morning Glory* planted in a box, and twined about the window? Do not these shew that the human heart yearns for the beautiful in all ranks of life?" Such ideas are not new to the readers of this work. If they do not always mirror themselves from the surface of its pages, it is because every one feels that the strong under-current is ever flowing in that direction. Next to the pleasure of expressing strong-felt convictions, is the delight of finding that these are in unison with the opinions of the gifted and the good. The above extract is culled from a beautiful short sketch of the "Tea Rose," from the pen of the able, right-hearted American writer, Mrs. Stowe. I have long felt, and said, that the

beauty and variety of flowers was one of the strongest material proofs of the beneficence of the Deity. Had it been intended, we should be satisfied *merely* with the *useful*—had it been designed, we should prize and aspire after nothing but what was essential to the supply of our *necessities*—as some are yet hardy enough to contend ought to be the extent of the ambition of the working classes—then is it not likely “we should have only coarse, shapeless piles of provisions lying about the world, instead of all this beautiful variety of trees, and fruits, and flowers?”

One of the features of the times is the enlisting of this feeling of the beautiful as a successful agent in effecting mental refinement and social elevation. Who has not thus seen and felt its power? The cheap but pretty dress; an elegant piece of furniture; a handsome chimney ornament; an artistic-moulded tea-pot; a healthy, clean plant; a cottage, whose very outside says it *must* be kept in order; each and all of these have, at times, done more to promote cleanliness and thrift than the reiterated arguments of moral suasion. Every such object is a standing, ever-present rebuke to filth and sloth. I know there is many a complaint, because in dress, &c., working-people will imitate their betters; but unless carried to an imprudent extreme, I should be a lenient judge in such matters. I confess, on the other hand, that I begin to see traces of manly self-respect, when the young villager *dons* a coat that fits his body, and *doffs* the over-all and cover-all of a sack, called a smock-frock. But, waving such matters, I may be allowed to state, that very many proofs have come under my own observation, in which access to, and love for, the *beautiful*, has completely changed for the better the habits of those subjected to its influence. Nay, more; my own experience justifies me in saying, that so far as *floral beauty* is concerned, in the closeness of the investigation, in the admiration and pleasure perceptible, and in the perfect order, integrity, and propriety of conduct manifested when admitted to range at will within the precincts of a garden, the hard-working men and women of our villages and towns will hardly rank second to any class of the community. Where there is the will, much good may be done without involving either great public show or much self-sacrifice. The Crystal Palace wiped off the unmerited stigma that we were such Goths and Vandals, that our admission amid works and scenes of beauty would just be synonymous with their destruction. We had proved the allegation to be unfounded years before, so far as this neighbourhood is concerned, though I have been given to understand that the county of Herts has not been superlatively distinguished for refinement.

I consider it, then, as a fact proved, not only that floral beauty exerts an elevating power, but that the opening of private gardens, at certain times, to the community, would be considered alike a boon and a source of pleasure. Of course, I make no allusion to such princely places as Trentham and Chatsworth, whose noble proprietors, with large-souled liberality, open their demesnes to visitors every day. Many who could not afford this might yet appropriate several days during the season. I have been urged by many, whose opinion I respect, to mention the method adopted here lately. I retorted, that if it pleased them they had better do it themselves; but then they were so awfully afraid of printer's ink! This was the standing excuse of a friend, who has held some of the highest gardening appointments in the country, and who has repeatedly urged me to make it more public, because it might do great good. If the practice becomes somewhat common, I shall certainly consider this paper one of the most useful I ever wrote.

If I use the plural *we*, it is to avoid confusion, as, properly speaking, as a servant, I could not use the

singular *I*, the modes successfully adopted being either suggested or sanctioned by my worthy employer. When first we began to make a show in the flower-garden in summer, there were a great many visitors, for the largest gardens in the vicinity were far from presenting that high culture and great interest which they *now* do. No gardener of his own accord can well be uncivil to visitors, though I often found they came at most unpropitious periods, when the whole attention and force were required for a definite object. Many, to avoid this, especially if one of the party had ever crossed words with me, used to come after the men had left in an evening, and thus broke in upon the little time I looked upon as peculiarly my own. It is no use denying, therefore, that there was a spice of the *selfish* that led me to agree to the proposal to open the garden to the public one day in the week, during two or three months in the season, and, unless in special exceptions, then *only*. In doing so, for some time I adopted the usual custom of sending an attendant round with each party; but frequently these were so numerous, especially when several villages would turn out the same day, that many would be kept waiting; and then individuals would come and ask “if they might not go round a second time?” These, and other considerations, led us to dispense with the attendant system altogether. We think we make some little improvement every year. Last summer, the gardens were open ten days in as many consecutive weeks, and instead of the whole day, the period was from one, P. M., to six, P. M. Previously to that period, the garden-men had been told of the place they were to occupy at work during the afternoon; so posted, they could see the principal parts, and so as to answer any inquiry that might be put. At the named time, the doors were opened, and people were free to come and free to go: some staying an hour; others several; and others, again, the whole time; there being no porter to admit, and no toll-gate man to let them out.

Has it answered? Last summer, on one of these days, I stood by the side of a great gardener from a large establishment. “I am glad I have come to-day; what a company you have got—the majority are working classes, aint they? How happy they seem! how clean and nicely dressed they are! They seem to go where they please; have you no attendants?” “No.” “Don't you find great mischief done?” “None at all.” “Well, even with attendants, we found ornaments missing from temples and grottoes, &c.; how is it? You don't seem to have even such a thing as an admonitory ticket.” “Can't say; only there *is* something in treating people so as to show you trusted in their honesty and honour.”

Has it given *universal* satisfaction? No! it would be a wonder if it did. Many, who used to come often when they could have the place to themselves, now seldom appear. They are the *betterer* ranks of people—the would-be-aristocracy of the middle classes—the very first to notice, if not to rail at, every other *exclusiveness* except their *own*. Some have told me it was a *pity* the privilege was made so *common*. Others have sent nice little notes, hoping that they, their friends, or families, might come at some other hours and times different from that set apart for the use of the public. Ah! many will talk nicely, and even do a little towards improving the public, provided they are not brought into close personal contact with it. If, however, the test of numbers when the novelty was gone, and faces that spoke of pleasure, be any sure guide, then I may safely say the satisfaction was *general*; and surely the diffusion of rational happiness, even for a few hours, with the after-thoughts and resolves linked and blended with it, is a something worth aiming and trying for.

Keeping in view the ideas with which I commenced, I should like to have something practical, however simple, for a conclusion. Ideas broached on cottage

and window-gardening have brought me statements from various parts of the country. The other day, I had a most interesting letter from the north of Scotland, a few extracts of which I will now give, as bearing upon the "beautiful," leaving others to another time.

"J. —, came quite out in window-gardening. Fine plants of scarlet Geraniums, *Kentish Hero* Calceolarias, and Fuchsias, graced the window-cell, with Nasturtiums, and Canary plants trained up the side, a little amongst the ivy. *People stood and looked as they passed*; it seemed quite a new dodge to the natives. Altogether, it gave the house a very gay and cheerful appearance. Some Hyacinth-glasses, filled with beautiful grasses, which stand on the chimney-piece, look very nice at this season of the year. Could you not launch into *THE COTTAGE GARDENER* an article on Grasses, if so be *dead* flowers were not foreign to your proscribed bounds. I am sure a very interesting graminaceous group might be formed for a few pence. The pots or receptacles, ornamental, if come-at-able, could be filled with moss, with some of the best on the top, and the grasses stuck into it; tufted-growing sorts could be put in so as to appear as tufts; and the looser growing ones could be ranged according to their habits. A few branches of Everlastings might be put in amongst them, by way of variety and embellishment. To cottagers of limited means, a group of this sort, even on the window-sill, might be a great source of enjoyment, at once cheap, pleasing, and interesting."

I can confirm the above statement. Knotted grass, Feathery grass, and Shaking grass, &c., have been coming into vogue in this neighbourhood for two years, and that solely owing to the example of a young lady, a tradesman's wife, who ranged the hedge-sides for them about the time they were in bloom. She lived in a pretty cottage by the highway-side. In ordinary cases, it would have presented nothing *extraordinary*; under her tending care it became a miniature Paradise for neatness and beauty. At a pinch, she has frequently been known to *clip* and clean her grass-plot in a morning; but her next to ubiquitous movements were not confined to garden and house. The love of the beautiful was no dreamy inoperative principle with her. It acted itself out in kindness and sympathy. Hear of an accident, a heavy misfortune, a severe case of affliction, and you hear of that woman having been there, to cheer, to console, to help by word and deed. She has removed to another part of the country, amid the regrets and the warm sympathies of a neighbourhood. But the influence of her little garden and her large heart have *not* gone. Every bunch of feathery grass keeps her in remembrance.

A few bunches of Everlasting Flowers between the bunches of grass are a great improvement in such groups. The other day I saw a bunch of the flowers of *Aphelaxis* so used. The whole of that genus, and also *Phenocoma*, *Helichrysum*, *Gnaphalium*, and *Xeranthemum*, may be so employed. *Gnaphalium arenarium*, *graveolens*, and *candidissimum*, are low-growing, hardy, herbaceous plants that any cottager may grow by the side of a pathway. They are now generally grouped under *Helichrysum*. The first-named has beautiful yellow flowers, which will retain their beauty for years, though I cannot say where it is to be had, as this bedding-system is making sad havoc with fine old plants. Then, there are the *Xeranthemums*, free-growing annuals, which require to be sown in April, in common soil, and though they grow generally three feet in height, yet the flowers, when well dried, will keep their colour for years. Such low-growing, hardy annual *Gnaphaliums*, as *obtusifolium*, *sanguineum*, and *undulatum*, may be so used, and all present a very pretty effect.

R. FISH.

THE CHRYSANTHEMUM.

A CORRESPONDENT (*Cato*) has written requesting information respecting the cultivation of this very fine autumnal flower, so as to produce such blooms as Mr. Taylor exhibited at the Stoke Newington Show on the 23rd of last month, and also a list of the best varieties, to enable him to select a collection from. I did write a short paper or two on the culture of the Chrysanthemum some two years back, and the heads of those papers are in the Dictionary also. Since those papers were written there has been a great improvement both in culture and in the varieties, so that I think a few additional instructions, and a list of the best varieties, will be acceptable not only to "Cato," but also to our readers generally, especially such as do not possess the entire *COTTAGE GARDENER*, or *The Cottage Gardeners' Dictionary*, though I may venture to say the latter work ought to be in the hands of every cultivator of plants, fruits, or vegetables, in Great Britain.

There is one recommendation to the *Chrysanthemum* that no other florists' flower possesses, and that is, it is so easily kept through the winter. All the rest, if I except the Rose, and perhaps the Fuchsia, have a difficulty about them which renders their preservation unscathed through that dreary season a matter of care and uncertainty; but the *Chrysanthemum* may be preserved with the least care imaginable, either in a pit or cold frame, or even out-of-doors, if the pots are plunged over head in coal-ashes, placed on the south side of a wall, or low evergreen hedge. The only protection they require is a light covering, in very severe frost, of dried bracken or common fern.

In addition to this extreme hardihood, this plant is as easy to propagate as a willow, every cutting will grow, and it can be propagated also by layers and seeds. I will briefly describe these three modes.

By Cuttings.—The best are the young tops, taken off when four or five inches high; reduce them to three inches in length, cut off the extreme top, and about an inch of the bottom; trim off the lower leaves, and put the cuttings round the edge of a five-inch pot, filled with light rich earth, and a thin layer of pure sand on the surface; then give a gentle watering, and place them on a heated surface of sand, or plunge them in a gentle tan-bed, placing a large hand-glass over them. This should be done as soon as the shoots can be got, in order to have them in a forward state early in the year. They will, with moderate care as to shading and watering, soon make roots, and should be immediately potted off into small pots; let the tops be cut off again, and subject them to this treatment every time they are potted, in order to cause side-shoots to break out, and thus form low, bushy plants early in the season. This is a desirable point to accomplish as soon as possible; for if they once get legs, long as a greyhound, their beauty is spoiled for that season: no cutting down afterwards will effect a reformation in their appearance.

By Layers.—The branches, when simply brought down to the soil, emit roots plentifully. This facility of rooting is taken advantage of to obtain low bushy plants. To effect this, plant out in an open situation a lot of old plants. If the plants are laid sideways when planted, the shoots can be pegged down into small pots more easily. These make low, bushy plants, well furnished with flower-buds, with very little trouble. Cut the layers off as soon as the pots are filled with roots, repot them into six-inch pots, and shade for a few days until they are fairly established, then treat them as you would the plants raised from cuttings.

By Seed.—This is not very plentifully produced in our dark, foggy climate, but it is produced in green-houses sparingly. Save and dry, and keep it dry till February or March. Then sow it in shallow pots, in

light, rich soil; sow shallow, and cover slightly with very fine sifted soil, giving very gentle waterings when the soil is dry. The young seedlings are very succulent, and soon damp off if too freely watered, or in too damp heat. The best place for them is on a shelf close to the glass of a good greenhouse. Prick out the seedlings, as soon as they can be taken hold of, into the same sort of shallow pot, and when they have made a still further growth, pot them singly into three-inch pots, and afterwards treat them as you would cuttings. Some may flower the first year, but they will all certainly bloom the second. This is the only way to procure new and improved varieties.

To cultivate the *Chrysanthemum* with a view to exhibit it, some extra care must be devoted to it. During the time of growth, the plants should be fully exposed to sun, light, and air. They should by no means be crowded together, or amongst other plants. The best situation I ever found for them was in a single row, on the side of an open walk. In this situation, from May to August, they will grow bushy, be furnished with broad, healthy foliage to the pot edge—that is, if rightly managed in three particulars, namely, repotting in very rich soil; freely watering at the root (occasionally with liquid manure), and frequently syringing over the leaves and branches; and, lastly, frequently stopping. At the end of August they should be in nine-inch pots, and then should be stout, bushy plants, with the flower buds in abeyance, or dormant. The buds should just make their appearance in September, and grow on slowly till October. The plants will then be really handsome objects, independent of bloom, and will require no sticks, nor any kind of support.

In order to have a greater show of bloom, some growers place three or four plants in a pot, but I cannot commend that practice. A greater number of flowers is obtained, it is true; but it is at the cost of a sacrifice in the size. The largest and finest flowers are always produced on single plants, and no censor will give a plant a prize in preference because it has a greater number of inferior blooms upon it. If not intended for exhibition, the placing a number of plants in a pot or tub may be a praiseworthy practice. I saw, very lately, in the conservatory in the Royal Botanical Society's Garden, in Regent's Park, a box, more than two feet across, closely filled with many plants of a tasselled-flowered *Chrysanthemum*, and a fine object as a mass of bloom it certainly was; but when the flowers were examined individually they were very common-place indeed. I have, in my greenhouse, several pots, with three or four plants in each, which, viewed at a distance, are very passable—nay, even showy; but they are not fit for an exhibition. "Cato," and every grower for exhibition, then, will be wise if they adopt the single-plant-in-a-pot system, if they wish to have really large, good flowers, either to be exhibited in pots or cut blooms.

(To be continued.)

CONSERVATIVE WALLS.

(Continued from page 184.)

WHAT is the use of a *Conservative Wall*? Previously to putting up any building, the first consideration is, of what use is it? That is the question. To the strict utilitarian, whose ideas are confined to the profit and loss on any undertaking, the conservative wall will appear a perfectly useless building; the objects to be grown against it are useful neither for food nor clothing. To a mind so narrowed, I cannot produce any argument to prove that a wall to be covered with ornamental and flowering shrubs is of any use. He could easily understand that a pinery, a vinery, or a peach-house would

be of some use. The fruit would be fit to eat! and would be a pleasing enjoyment after dinner, accompanied by a glass of good wine. I do not deny this, by any means; and, in addition to the mere eating of such delicious fruit, there is, to a more elevated mind, quite as much enjoyment in seeing such fruits bloom, grow, and come to perfection. To a mind still more refined, there is a still higher enjoyment in cultivating and bringing to a high state of perfection plants cultivated only for their fine foliage, or highly-perfumed beautiful flowers, the gems of the earth. Shakspeare says, "the man that delights not in music is not to be trusted;" and I may venture to say, that the mind that delights not in flowers cannot be very amiable!

Now, the use of a conservative wall is to grow plants against it to a higher state of perfection than they can be grown in pots, more especially such plants as will not quite bear the vicissitudes of our climate. For such purposes it is admirably adapted; and this is no theory only, it has been borne out in practice in various places—private gardens. I mentioned some in my last paper on this subject, and now I need only refer to the conservative walls at Kew and Chiswick, as instances of public gardens, where they may be seen clothed with beautiful specimens of plants in the greatest luxuriance. But there is another use of plants grown in this manner, and that is, the proving their capability of bearing our climate. Many plants are imported from warmer climates, of whose power to resist or bear our frosts we have no knowledge. I remember the day when the *Aucuba Japonica* was cultivated in the greenhouse only, and now every tyro in gardening knows that it has proved one of the hardiest of our evergreens. Had conservative walls been in existence then, this plant would have been planted against it, and its perfect hardihood proved at once. Again; if there is any truth in the doctrine of acclimation, or the art of hardening, this wall is a proper school for the plants; and it would be a very interesting pursuit to endeavour to acclimatize plants by placing them first against and under the sheltering influence of such a wall previously to planting them out in the open border, when they had acquired a woody texture; for it is a well-known fact, that old hard-woody plants will bear a greater degree of cold than the same plants when young and soft-wooded. And, thirdly, plants against such a wall are more certain to bear seed than such as are grown in pots, or even in the borders of a conservatory, for this reason—in such a situation they are more likely, nay, certain, to produce seeds, from the fact that they have more of the stimulants (air and light, combined with protection) to cause such a natural effect. The production of seed is a step gained in the art of hardening plants, because it is supposed that plants raised from seed saved in a colder climate than their native habitat will have a more robust constitution, and thus, by a natural process from generation to generation, the great grand-children of plants brought originally from Japan or Mexico will be as hardy as our oak or hazel. I do not say positively this will be so, because I do not forget that the *Dahlia*, the *Potato*, the *Cucumber*, and the *Melon*, are probably as tender now as they were the first year of their introduction; but it is plants with a more woody texture that would probably be acclimatized, if the art of hardening by a conservative-wall were systematically and judiciously carried on for several generations.

Such is my answer to the question, What is the use of a conservative wall? and I think the reasons given are quite sufficient to bear out the idea, that it is a useful as well as a beautiful object; and then follows the second query, How is it to be built? The answer to this will include the aspect, material, and the mode. The aspect of that model of a conservative wall at

Chatsworth is nearly due west, and though, in that instance, the aspect is of little consequence, because of its being heated, yet, in the case of a wall not heated, that aspect is, I conceive, the very best, and for this reason, should a frost happen any night, the plants may be slightly touched with it, but will have time to be gradually thawed before the sun reaches them, and so be less injured than they would be if the wall had an east or a south aspect. For the sudden extremes of heat and cold, or *vice versa*, are the circumstances so destructive to half-hardy plants. Even a north is better than a south aspect, though not to be preferred for many plants; yet the *Camellia* thrives best on a north aspect if planted out-of-doors. Several instances of this may be seen at Chiswick. They are planted there close to a wall on the north side, and grow well, and frequently flower well too, if there is a season without late spring frosts. The reason of this is easily understood; they are not subject to such sudden and violent changes of temperature as they would be if planted against a wall with a south aspect, and so are not stimulated into growth so early in the season as to be nipt by the frost.

The west, then, is the best aspect for the generality of plants suitable for a conservative wall, and the material I consider the best is a dark-coloured brick; dark colour retains the heat, light colour repels it; hence it is, that a black coat is warmer than a white one on a sunshiny day. If the dark wall has had the sun shining upon it the whole of the afternoon, it will retain the heat much longer than a light-coloured one. This is a fact I need not prove. Then a dark brick should be the material, if the wall is not heated artificially. The way or mode by which this wall should be built, is first to lay a good foundation, broader than ordinary, in order to allow space to have a hollow space in it, whether it is to be heated or not, for that is a fact now well understood, that a hollow wall is warmer than a solid one. Indeed, all garden-walls, whether for the purpose of growing plants or fruits, should be constructed in this manner.

T. APPLEBY.

(To be continued.)

THE BIRMINGHAM POULTRY SHOW.

SEVERAL attempts have been made, of late years, with more or less success, to trace the history and origin of our different varieties of domestic poultry. There is, however, no difficulty either in ascertaining the commencement of those exhibitions which have done so much to improve the quality, and to extend the taste for the purer and better breeds of poultry, or in tracing the steps by which they have, in a wonderfully short space of time, obtained gradually, and almost imperceptibly, their present high position.

To the Yorkshiremen, we are undoubtedly indebted for having originated and brought to a considerable degree of maturity these interesting gatherings; and we remember the time when it was thought almost a reproach upon the proverbial shrewdness of our Yorkshire friends, that they had given themselves so much trouble upon what had been long considered so trifling a subject. They, however, persevered, and soon established, within the circumference of a few miles, poultry shows at Leeds, Bradford, Huddersfield, Halifax, Keighley, Otley, Weatherby, Holmfirth, Stanwood, and Bretton, each of which, in its locality, is well supported.

But it remained for the Birmingham and Midland Counties Society to make the attempt on a large scale. They soon succeeded in establishing an exhibition which has not yet been approached either in point of numbers or of excellence; and they are fairly entitled to divide with their more northern brethren the credit of having revived and brought to its present state of advancement this interesting and profitable branch of rural economy. Poultry, which had been looked upon by the farmer as beneath his notice, has now, by their exertions, become a source at once of profit and of pleasure; and, in proportion

to the food it consumes (much of which would otherwise be wasted), and to the capital and labour employed, is, we undertake to say, as remunerative as any stock upon his farm. To the country gentleman, the amateur, and the fancier, what so ornamental, and at the same time so useful, as a nice, uniform lot of pure-bred fowls? The ladies, too, may participate both in the amusement and the benefit derived from their feathered favourites, from the stately Shanghai, and the brilliant Spaniard, down to the little dapper Golden or Silver Sebright Bantam, rivalling the pheasant in beauty. And—last, not least—can a cottager keep anything about his premises from which he and his family may derive more of mingled pleasure and profit than a few heads of good poultry?

For the gratification, and, we trust, for the benefit, of all classes of our readers, it is to a description—impartial, we hope, and not unprofitable to the poultry-keeping world—of the fourth exhibition at Birmingham, that we purpose to-day to devote a greater proportion of our paper than is usually given to one subject.

This exhibition commenced on Tuesday, the 14th of December, in the capacious and well-lighted building known as Bingley Hall. Considerable improvements have been made in the hall itself since the last show took place within its walls, and the visitors are indebted to the proprietors and the committee for a corresponding increase in the comfort they enjoy, and the facilities afforded to them in viewing the specimens. Indeed, the arrangements in these respects appeared to us to be quite unexceptionable.

In point of numbers, the exhibition of 1852 exceeded that of 1851 in every class, as the following table (which may be interesting for purposes of reference) will show:—

Classes.	PENS ENTERED.	
	1851.	1852.
Spanish	53	61
Dorking	117	142
Shanghai	154	275
Malays	35	10
Game	127	164
Golden-pencilled Hamburgs ..	20	13
Golden-spangled Hamburgs ..	21	28
Silver-pencilled Hamburgs ..	48	58
Silver-spangled Hamburgs ..	44	66
Poland	41	68
Cuckoo	5	6
Rumpless	6	4
White-crested Golden Hamburgs	2	—
Andalusian	5	2
Ancona	6	1
Frizzled	1	4
Norfolk or Surrey	2	2
Bantams, Gold-laced	20	35
" Silver-laced	11	6
" White	10	12
" Black	16	13
" other varieties	6	5
Pigeons	120	85
Geese	17	18
Ducks	71	73
Turkeys	25	23
Guinea-fowl	14	6
Extra Class	36	—

The managers of the show have this year omitted some of the varieties, or sub-varieties, included in the list of last year. With all due deference, we question the propriety of this alteration. Although principally got up for the benefit of the farmer and the amateur, these exhibitions are interesting to the scientific naturalist, and have derived, in their time, much benefit from his investigations and researches. To him, independently of their beauty, and the pleasing variety they made, the specimens entered last year as "Ornamental Poultry," and several curious sub-varieties besides, were of peculiar interest, while they were objects of attraction to others also. We hope to see room afforded, upon future occasions, for specimens of this description.

We should also strongly recommend a reconsideration of the rule which permits old and young fowl to be shown in competition in the *same* classes. Where there are classes

for chickens exclusively, *all* chickens should, in our opinion, be shown in them. In many varieties, especially of what are known among fanciers as "feathered fowl," old birds are shown to a great disadvantage against chickens, whose feathers are necessarily more *clean and pure* in colour; and in every class this practice admits of a sort of speculation on the part of the judges, whether or not the chickens *will* some day be better than the old fowls *are* now; instead of their being confined, as, we submit, they ought to be, to a simple, because certain, decision which of the two or more pens is the *best at the time of the show*.

Before we proceed to notice the different classes, we will mention the only other drawback—and in our opinion it is a serious one—to the Birmingham Show. It is the very objectionable practice of employing a dealer as one of the judges. To it may undoubtedly be traced the dissatisfaction, "not loud, but deep," expressed by many good judges, both at the last and the present show, with some of the awards made. We have no personal feeling in the matter; it is to the *principle*, and not to the individual, that we object. It is not in the nature of things that the confidence of the public should be placed, or expected, in any man who may be the seller of the very birds of which he is called upon to judge. It is to inspire confidence on the part of the exhibitors—not to attach suspicion to the judges—that we thus contend that dealers should not be eligible as judges. The task of finding fault is always an invidious one, but as public journalists, and having the public good exclusively within our view, we cannot be silent upon a point which is operating much to the disadvantage of exhibitions, which we are convinced, although yet, as it were, in their infancy, have done, and are doing, much good; the more especially when *we know* the opinions of many of the owners of the best stock, and that gentlemen of the highest character and honour, and who are as good judges of poultry as England can produce, have repeatedly refused to act in the capacity of judges at our shows, on the ground alone, that they will not, by becoming their colleagues, countenance the engagement of dealers as judges. Hence it is clear that more is lost than can be gained by employing the latter. We are by no means sure that the Birmingham committee themselves have not met with such refusals this very year; but we know that in the recent case of the Hitchin show, Birmingham itself, York, Leeds, and Hull, were ransacked up to the very day before the show took place for a judge, and that there was no other difficulty in the way. For these reasons, we very sincerely trust that this manifest evil will be remedied another year, before its consequences are more severely felt; that confidence, lost in some, and waning in many amateurs, may be restored; and that, all cause of suspicion being thus removed, the decisions of the judges will be acquiesced in with that respect which confidence can alone inspire.

We now turn, with pleasure, from the ungracious office of fault-finding, to the details of what has been altogether—in spite of the drawbacks arising from the causes to which we have just referred—one of the best shows of poultry (if not the very best) upon record.

We need scarcely say that the classes, where there were so many, were unequal in point of merit. Following the orders of the catalogue, we commence our observations with the *Spanish*. Until the Cochins became, within the last year or two, dispersed throughout the country, no race of fowl were greater favourites than the Spaniards. The brilliant lustre of their sable plumes, contrasted with the white face and red comb—their size, their stately and upright carriage, combine to make the male bird one of the most beautiful of our domestic fowl; while the glossy and uniform appearance of the hens render a nice flock of Spanish most agreeable to the eye. So much so, indeed, that they are often styled "the gentleman's fowl."

In point of quality, the birds exhibited appeared to us to be much superior to those of last year.

In our recent account of a visit to his poultry-yards at Knowsley, we took occasion to say, that he who should beat Captain Hornby in the Spanish classes, at Birmingham, must show good birds in their best form. We were not far wrong, for the Captain has certainly made a tolerably clean sweep of it in these classes, having carried off the first and second prizes (the latter, in our opinion, being the better

pen). In the Spanish chicken class, the first prize was awarded to Mr. J. O. Smith, of Skelton Grange, near York; and we think his birds well deserved the honour.

The next classes comprise the different varieties of the *Dorking family*; and we think the committee have taken a mistaken step in offering separate prizes for Dorkings with double or rose combs. Such, in our opinion, and in that of most of the best judges, so far as we have been able to collect them, are of questionable purity as Dorking fowls, and, at all events, are quite unworthy of separate premiums at such a show as that of Birmingham. The grey and sober plumage of the Dorkings presents an agreeable contrast to the more gay feathering of some of their competitors; and their peculiarly neat and "squat" build points them out, as in truth they are, as the very fowl for the table. The advantage of the Dorkings is, that their meat is packed into a small compass, and, for the purposes of the cook alone, we are not sure that the Dorking does not bear away the palm from all competitors. But, taking all points together (and we may as well repeat that, in giving an opinion of the relative merits of different varieties, we have always in view the question—which of them combines the *most* good qualities with the fewest defects), we are of opinion that the Shanghaes and Spanish are superior to the Dorkings. In these, as in the Spanish classes, the number of pens was greater this year than last, and we think their contents at least equal in quality. The first prize in the principal class was awarded to T. T. Parker, Esq., of Sutton Grange, for a splendid pen of birds; the second falling to the lot of Captain Hornby, for one scarcely inferior to it.

We have already said that the general verdict of the poultry-keeping world has, in our opinion, in spite of the hue raised against them by the dealers, indisputably been pronounced in favour of the *Shanghaes*; and we think, taking all points into consideration, correctly so. In point of beauty, opinions may differ; but their great bulk, added to neat and compact appearance, their fecundity, and the ease with which they may be kept within any enclosure, however slight, renders them, without regard to other considerations, a most desirable fowl. Their very singularities—the stumpy tail and feathered leg—are not displeasing by way of variety, and they are, moreover, quiet and gentle in habits and disposition to a degree. But, whether we be right or wrong in awarding to them, as we are at present disposed to do, the palm over all other varieties known in this country, certain it is that—for the present, at all events—they are the reigning favourites. The prices for which they have been, and are, sold; the length of time during which those enormous prices have been kept up; the interest concentrated upon them at every show we go to; prove, beyond cavil, that the fact is as we have stated. To this observation, their position at the Birmingham show was no exception. From day to day, and from hour to hour, the thickest of the crowd surrounded the pens containing the different sub-varieties of these beautiful birds. Since the last exhibition the Shanghaes have been divided into three classes—the whites, the cinnamons and buffs, and the browns and partridge-feathered. Why the greys and blacks have been excluded we are not aware. Taking the subdivisions in the order we have given, the white first claim our notice. Inferior in size to some of their relatives, yet upon a lawn, or in a clean country place, what can look prettier than a neat uniform lot of these beautiful birds? They have already become prime favourites, especially among the ladies, and, we think, are likely to continue so.

In this sub-division, which was superior, both in number and quality, to those shown in the same classes in 1851, the first prizes, both for old fowl and for chickens, were awarded to Mrs. Herbert, of Powick. The second prize for the old birds was given to Mr. G. C. Peters, of Moseley; and the third to Mr. George Graham, of Yardley, whose pen appeared to us, and to many others, to be at least equal to the other two.

Of the numerous shades of colour prevailing among the Shanghae fowl, none has become so popular as the neat and pretty buff; and certainly there is something peculiarly pleasing in its quiet uniformity. Whether from this or other causes we know not, but the buffs have certainly commanded higher prices than those of any other colour. It is, therefore, not surprising that in this class the greatest

interest appeared to be centred—so much so, that it was really difficult to obtain time and space sufficient to get a good view of them. In every show the “observed of all observers,” here, where the best of each sort are congregated together, we have a right to expect the best of these also. Hence the interest they excited, which was certainly by no means disappointed. In one word, we can say nothing for the buff class which has not been said and proved by the preference everywhere accorded to them, although we really do not think this class was so good, as a whole, as the corresponding class of last year.

With regard to the dark varieties, we are not of those who, on the one hand, decry them; nor do we, on the other, think them, as some do, either more hardy or superior in weight to their light-coloured relatives. In truth, we think there are equally fine kinds of the buff, the cinnamon, and the dark varieties; and we know that it is difficult to find chickens, of any breed, more easy to be reared than are the buff Shanghaes. For those who reside near large towns we might recommend the darker birds, on the ground that it is better to keep good birds of a colour which is not so easily soiled, than to have birds of better quality, yet of a shade so light that they cannot be kept, in that locality, in perfect purity of plumage.

Reverting to the prize-list, we find that in the buff class of older birds Mr. Sturgeon maintains his old position—a higher he cannot attain. Mr. Cattell, of Moseley Wake Green, obtained the second prize; and Mr. Steggall, of Weymouth, the third. In the corresponding class of young fowls of 1852, the first prize was awarded to Mr. Cattell; the second to Thomas Roscoe (Captain Hornby's servant); and the third to Mr. Punchard. It was to the awards in this latter class that the greatest exception was taken; and, after much examination, we are bound to declare our opinion in favour of the malcontents.

Prizes were also given for the best pair of buff, cinnamon, or brown: the first to Dr. Gwynne, of Sandbach; the second to Mr. Punchard; and the third to Mr. H. G. Smith. Mr. Punchard also obtained a commendation for what was thought by many the best pen of the four; and this opinion was partly borne out by the fact, that the pair of birds were sold for £25. We wish Mr. Punchard as good a sale on the 4th of January as that which Mr. Sturgeon was fortunate enough to secure.

The next class, in order, are the *Malays*. These have hitherto been a favourite fowl; and certainly there is a stateliness and an appearance of high-breeding about a true Malay which is particularly commanding. We cannot but regret that so handsome and pure a breed of fowls should, all at once, have become nearly extinct; although we must admit, that in point of utility they are not equal to the Cochins, the Spanish, or the Dorkings.

Next in order, come the type of courage—the old English *Game*. The days of cock-fighting are happily at an end in this country, but we can still admire the martial appearance and bearing of the different sub-varieties of those truly “game” birds which were wont, in old times, to contend in the cock-pit. For beauty and variety of plumage, closeness of feathers, and purposes of utility combined, there is, we really believe, no one of the smaller varieties of our domestic poultry preferable to the Game. In the northern counties, the pitmen and cottagers prefer them to all other sorts within their reach; and the degree of perfection to which they are brought, if not so great as in the times when fortunes and estates depended upon the result of their encounters, is still considerable. To us they are interesting, as one of the “poor man's fowls;” and sure we are that a cottager can keep none upon less food, or to greater advantage, while they will never shame the poultry-yard of a gentleman. For the numerous prizes awarded, we refer to the list which we subjoin; and we think we may say, without fear of contradiction, that the Game classes were the best in the exhibition.

The *Pencilled Hamburg* next claim our attention. These, like the Game, are, though in different localities, the favourites of the cottagers. In the West Riding of Yorkshire and parts of Lancashire, there is scarcely a cottage which cannot boast of its few “Chittaprats,” as they are there called. As they may not be known to many of our readers, we may add that there is not a prettier race of fowls extant than the

Pencilled Hamburgs, whether golden or silver,—nor one, which, in proportion to its size, is of more real use to the farmer or the cottager. We cannot, however, say we think the collection of these pretty fowls was first rate. The golden were better than the silver ones—the latter, indeed, would not bear comparison with those exhibited at the small shows in the Yorkshire towns.

Following naturally in order come the *Spangled Hamburgs*, called in Yorkshire, where they also are principally cultivated, “gold and silver pheasants.” These, again, are beautifully feathered kinds; and, like the Pencilled varieties, capital layers; and, therefore, most useful to the poor man. Our Shanghae and Spanish fanciers would scarcely suppose that their poorer brethren in Yorkshire will discuss the merits and demerits of their Chittaprats, or gold or silver pheasants, and point out, to a feather, the difference between them, with all the zest and interest which they themselves bestow upon their own more costly and gorgeous favourites. And woe betide the judge, who, at one of the Yorkshire shows, should make a mistake in deciding between the pens of rivals, each as competent, or more so, to exercise a judgment as himself.

Of the *Polish* fowls, which are next in rotation, so much has been said of late, that, without meaning at all to disparage them, we shall not be at all surprised to find that some of our friends, who have purchased them of the dealers, may discover, before long, that they have got considerably less than their “pennyworth for their penny.” Yet the Polands, of which there are several tolerably distinct varieties, are exceedingly pretty, and are, moreover, for their size, useful fowl. The plumage of the blacks, which almost equals that of the Spanish in brilliancy, is contrasted to advantage with the pretty white crest which is common to both sexes. The Golden and Silver Polands have the latter characteristic in the same perfection; and although the contrast between the black plumage and white crest does not hold good, it is more than made up for by the beautiful markings of the varieties now under notice. The Polands are, by the efforts of the dealers, rising in favour; and although we are not prepared to say that it is not deservedly so, yet we are sure that the prices which have been given for them are perfectly ridiculous, and such as never can be maintained. For the several prizes awarded, we refer to the list, only adding that the Polands, as a whole, are decidedly an improvement upon the last year's show, and added considerably to the interest of the exhibition.

Of the *Bantams*, generally one of the prettiest features of a large gathering like this, we shall only say that they were decidedly inferior in quality to those shown at many of the minor exhibitions.

We do not think that either the *Geese* or *Turkeys* were so good as those exhibited on former occasions.

Of *Ducks*, some good specimens were exhibited; and the Aylesburys shown by Lord Hill were well worthy of the first prize awarded to them, as were the Rouens of Mr. Charles Punchard, which, in their class, obtained a like premium.

Upon the whole, we do not hesitate to say that the Show of 1852 was not, in point of general merit, at all superior to its predecessor. We doubt if so many good birds were shown; and we are sure there were more of a decidedly inferior character. There are several reasons, combining probably, to produce this result. We have already adverted, not without pain, to some of them; and we submit, in conclusion, to the managers of future anniversaries, that the time for which the birds are kept is really too long. If one day was given up, so that the birds need not be brought in until the Monday evening, two days would be gained to them; and we hope and believe nothing would be lost to the exhibition or to the public. Sure we are that exhibitors would be better satisfied; and we are strongly inclined to think that the owners of many good birds, who now keep them at home, would, if this and the other objections to which we have, in no unfriendly spirit, thought it our duty to advert, were obviated, no longer object to send them to Birmingham. If the Show is to be kept up at all upon the scale it has already attained, to say nothing of improvement, most of these points must necessarily force themselves upon the attention of those in office. This is our only object in putting them forward; and we very sincerely trust that all

causes of jealousy and suspicion being removed, the subscribers will work harmoniously together; and that we may for many years look upon the Exhibition at Birmingham as a standard Poultry Show.

We publish the full prize-list, as follows:—

Class 1.—SPANISH.

(For the best Cock and three Hens of any age.)

5. First prize, 2*l.* 2*s.*, Mrs. Windham Hornby, Knowsley Cottage, Prescot.
3. Second ditto, 1*l.* 1*s.*, Captain Windham Hornby, Knowsley Cottage, Prescot.

Class 2.—SPANISH.

(For the best Cock and three Pullets, Chickens of 1852.)

25. First prize, 1*l.* 1*s.*, Mr. John Hill Smith, Skelton Grange, York.
33. Second ditto, 10*s.*, Mr. Richard Taylor, Ward End Mills.
27. Third ditto, 5*s.*, Captain Windham Hornby, Knowsley Cottage, Prescot.

The whole of this class highly meritorious.

Class 3.—SPANISH.

(For the best Cock and one Hen of any age.)

58. First prize, 15*s.*, Mr. John Henry Peck, Wigan.
56. Second ditto, 10*s.*, Mr. John Taylor, jun., Cressy House, Shepherd's Bush, London.

Class 4.—DORKING (Single-combed).

(For the best Cock and three Hens of any age.)

95. First prize, 2*l.* 2*s.*, Thomas Townley Parker, Esq., Sutton Grange, St. Helen's, Lancashire.
72. Second ditto, 1*l.* 1*s.*, Captain Windham Hornby, Knowsley Cottage, Prescot.

Class 5.—DORKING (Single-combed).

(For the best Cock and three Pullets, Chickens of 1852.)

109. First prize, 1*l.* 1*s.*, Captain Windham Hornby, Knowsley Cottage, Prescot.
113. Second ditto, 10*s.*, Mr. James Drewry, Newton Mount, Burton-upon-Trent.
119. Third ditto, 5*s.*, Mr. Edward Lister, Cassia Lodge, near Over, Cheshire.

The whole class highly commendable.

Class 6.—DORKING (Double or Rose-combed).

(For the best Cock and three Hens of any age.)

139. First prize, 2*l.* 2*s.*, Miss Elizabeth Steele Perkins, Sutton Coldfield.
141. Second ditto, 1*l.* 1*s.*, Mr. John Huskins, Wilnecote, near Fazeley, Staffordshire.
138. Third ditto, 15*s.*, The Reverend John Robinson, Widmerpool, near Nottingham.

Class 7.—DORKING (Double or Rose-combed).

(For the best Cock and three Pullets, Chickens of 1852.)

143. First prize, 1*l.* 1*s.*, Mrs. Windham Hornby, Knowsley Cottage, Prescot.
146. Second ditto, 10*s.*, Sir John Cathcart, Bart., Cooper's Hill, Chertsey, Surrey.
150. Third ditto, 5*s.*, Mr. James Drewry, Newton Mount, Burton-upon-Trent.

Class 8.—DORKING (Double or Single-combed).

(For the best Cock and one Pullet, Chickens of 1852.)

163. First prize, 15*s.*, Mrs. Windham Hornby, Knowsley Cottage, Prescot.
175. Second ditto, 10*s.*, The Reverend M. W. F. Thursby, Abington Rectory, near Northampton.

Class 9.—DORKING (White).

(For the best Cock and three Hens of any age.)

188. First prize, 2*l.* 2*s.*, The Right Honourable the Earl of Dartmouth, Sandwell.
194. Second ditto, 1*l.* 1*s.*, Mr. Joseph Jennens, Moseley, Birmingham.
Third prize withheld.

Class 10.—DORKING (White).

(For the best Cock and three Pullets, Chickens of 1852.)

205. First prize, 1*l.* 1*s.*, Mr. John Brearley Payn, Vicarage Road, Edgbaston.
200. Second ditto, 10*s.*, The Right Honourable the Earl of Dartmouth, Sandwell.
202. Third ditto, 5*s.*, The Reverend Edward Elmhirst, Shawell Rectory, Leicestershire

Class 11.—COCHIN-CHINA (Cinnamon and Buff).

(For the best Cock and three Hens of any age.)

225. First prize, 2*l.* 2*s.*, Mr. Thomas Sturgeon, Manor House, Grays, Essex.
212. Second ditto, 1*l.* 1*s.*, Mr. James Cattell, Moseley Wake Green, near Birmingham.
224. Third ditto, 15*s.*, Mr. F. C. Steggall, Weymouth, Dorsetshire.

Class 12.—COCHIN-CHINA (Cinnamon and Buff).

(For the best Cock and three Pullets, Chickens of 1852.)

294. First prize, 1*l.* 1*s.*, Mr. James Cattell, Moseley Wake Green, near Birmingham.
272. Second ditto, 10*s.*, Mr. Thomas Roscoe, Knowsley, near Prescot.
275. Third ditto, 5*s.*, Mr. Charles Punchard, Blunt's Hall, Haverhill, Suffolk.

Class 13.—COCHIN-CHINA (Brown, and Partridge-feathered).

(For the best Cock and three Hens of any age.)

335. First prize 2*l.* 2*s.*, Mr. Edward Farmer, Greet, Sparkbrook, near Birmingham.
338. Second ditto, 1*l.* 1*s.*, Mr. Thomas Atkins, Dursley, Gloucestershire, and Babbicombe, Torquay, Devonshire.
332. Third ditto, 15*s.*, Mr. Thomas Smith, Cheapside, Birmingham.

Class 14. COCHIN-CHINA (Brown, and Partridge-feathered).

(For the best Cock and three Pullets, Chickens of 1852.)

361. First prize, 1*l.* 1*s.*, Mr. Thomas Atkins, Dursley, Gloucestershire, and Babbicombe, Torquay, Devonshire.
355. Second ditto, 10*s.*, Mr. Charles Punchard, Blunt's Hall, Haverhill, Suffolk.
349. Third ditto, 5*s.*, George Tollet, Esq., Betley Hall, Staffordshire.

Class 15.—COCHIN-CHINA (Cinnamon and Buff, or Brown).

(For the best Cock and one Pullet, Chickens of 1852.)

406. First prize, 15*s.*, William Cust Gwynne, Esq., M.D., Sandbach, Cheshire.
408. Second ditto, 10*s.*, Mr. Charles Punchard, Blunt's Hall, Haverhill, Suffolk.

Class 16.—COCHIN-CHINA (White).

(For the best Cock and three Hens of any age.)

452. First prize, 2*l.* 2*s.*, Mrs. Herbert, Powick, Worcestershire.
458. Second ditto, 1*l.* 1*s.*, Mr. George Charlton Peters, Moseley, near Birmingham.
455. Third ditto, 15*s.*, Mr. George Graham, Yardley, Worcestershire.

Class 17.—COCHIN-CHINA (White).

(For the best Cock and three Pullets, Chickens of 1852.)

465. First prize, 1*l.* 1*s.*, Mrs. Herbert, Powick, Worcestershire.
470. Second ditto, 10*s.*, Mr. George Graham, Yardley, Worcestershire.
479. Third prize, 5*s.*, Mr. James Cattell, Moseley Wake Green, near Birmingham.

The Judges cannot too strongly impress on the exhibitors of Cochinchina fowls the danger they incur of losing prizes, to which they would otherwise be entitled, by exhibiting specimens with imperfect tails.

Class 18.—MALAY.

(For the best Cock and three Hens of any age.)

482. First prize, 1*l.* 1*s.*, Mr. Charles Ballance, 5, Mount Terrace, Taunton, Somersetshire.

Second and third prizes withheld.

Class 19.—MALAY.

(For the best Cock and three Pullets, Chickens of 1852.)

489. First prize, 15*s.*, Mr. Gervase Oldham, Nether Whitacre, Warwickshire.
488. Second ditto, 10*s.*, Mr. Charles Ballance, 5, Mount Terrace, Taunton, Somersetshire.

Third prize withheld.

Class 20.—GAME FOWL (White, and Piles).

(For the best Cock and three Hens of any age.)

495. First prize, 1*l.* 1*s.*, Mr. Henry Felthouse, Tamworth.
510. Second ditto, 15*s.*, Mr. Theodore Bullock, Hawthorn House, Handsworth.
502. Third ditto, 10*s.*, Mr. J. T. Wilson, Redditch, Worcestershire.

Class 21.—GAME FOWL (White, and Piles).

(For the best Cock and three Pullets, Chickens of 1852.)

527. First prize, 15*s.*, Mr. James Hand, jun., Amington Old Hall, near Tamworth.
523. Second ditto, 10*s.*, Mrs. G. A. Wilson, Redditch, Worcestershire.
518. Third ditto, 5*s.*, Mr. Edward Lowe, Comberford Mill, near Tamworth.

Class 22.—GAME FOWL (Black-breasted, and other Reds).

(For the best Cock and three Hens of any age.)

544. First prize, 1*l.* 1*s.*, Mr. Edward Lowe, Comberford Mill, near Tamworth.
548. Second ditto, 15*s.*, Mr. Edward Glover, Olton Green, near Solihull.
560. Third ditto, 10*s.*, Mr. Benjamin Williams, Lovells, Handsworth.
The whole class commended.

Class 23.—GAME FOWL (Black-breasted, and other Reds).

(For the best Cock and three Pullets, Chickens of 1852.)

588. First prize, 15*s.*, Mr. Theodore Bullock, Hawthorn House, Handsworth.
591. Second ditto, 10*s.*, Mr. Henry Sewell, Upton-upon-Severn, Worcestershire.
596. Third ditto, 5*s.*, Mr. Thomas Roscoe, Knowsley, near Prescot.

Class 24.—GAME FOWL (Blacks, and Brassy-winged, except Greys).

(For the best Cock and three Hens of any age.)

622. First prize, 1*l.* 1*s.*, Mr. J. T. Wilson, Redditch, Worcestershire.
628. Second ditto, 15*s.*, The Reverend Charles D. Blyth, Sutton Rectory, Biggleswade.
620. Third ditto, 10*s.*, Mr. J. T. Wilson, Redditch, Worcestershire.

Class 25.—GAME FOWL (Blacks, and Brassy-winged, except Greys).

(For the best Cock and three Pullets, Chickens of 1852.)

631. First prize, 15*s.*, Mr. William Dester, Seckington.
Second and third prizes withheld.

Class 26. GAME FOWL (Duckwings, and other Greys, and Blues).

(For the best Cock and three Hens of any age.)

633. First prize, 1*l.* 1*s.*, Mr. William H. Austin, Norton, near Shiffnal, Shropshire.

642. Second ditto, 15s., Mr. Edward Lowe, Comberford Mill, near Tamworth.

646. Third ditto, 10s., Mr. John Hadwen, Kelroyd Bridge, Halifax.

Class 27.—GAME FOWL (Duckwings, and other Greys, and Blues).

(For the best Cock and three Pullets, Chickens of 1852.)

648. First prize, 15s., Isaac Avery, King's Norton, Worcestershire.

650. Second ditto, 10s., Mr. Francis Bullock, Hawthorn House, Handsworth.

655. Third ditto, 5s., Mr. William Smith, Kent House, Halifax.

Class 28.—GOLDEN-PENCILLED HAMBURGH.

(For the best Cock and three Hens of any age.)

662. First prize, 1l. 1s., Mr. John Royston Pearson, Chilwell, near Nottingham.

661. Second ditto, 15s., Mr. John Lowe, 6, Bull Ring, Birmingham.

659. Third ditto, 5s., Mr. W. B. Mapplebeck, 6, Bull Ring, Birmingham.

Class 29.—GOLDEN-PENCILLED HAMBURGH.

(For the best Cock and three Pullets, Chickens of 1852.)

668. First prize, 15s., Mr. James Oldham, Long Eaton, Derbyshire.

666. Second ditto, 10s., Mr. John Lowe, 6, Bull Ring, Birmingham.

665. Third ditto, 5s., Mr. Charles Brown, 47, Edgbaston Street, Birmingham.

Class 30.—GOLDEN-SPANGLED HAMBURGH.

(For the best Cock and three Hens of any age.)

677. First prize, 1l. 1s., Mr. Henry Clapham, Aireworth, near Keighley, Yorkshire.

680. Second ditto, 15s., Mr. James Dixon, Westbrook Place, Bradford, Yorkshire.

671. Third ditto, 5s., Mr. Thomas Smith, Brineton, near Shiffnal.

Class 31.—GOLDEN-SPANGLED HAMBURGH.

(For the best Cock and three Pullets, Chickens of 1852.)

692. First prize, 15s., Mr. Henry Clapham, Aireworth, near Keighley, Yorkshire.

686. Second ditto, 10s., Mr. Thomas Smith, Brineton, near Shiffnal.

Third prize withheld.

Class 32.—SILVER-PENCILLED HAMBURGH.

(For the best Cock and three Hens of any age.)

697. First prize, 1l. 1s., The Honourable Mrs. Astley, Swanton House, Thetford, Norfolk.

709. Second ditto, 15s., Mr. Benjamin Dain, Slade House, Aston, Birmingham.

698. Third ditto, 5s., The Right Honourable Viscount Hill, Hawkestone, Salop.

Class 33.—SILVER-PENCILLED HAMBURGH.

(For the best Cock and three Pullets, Chickens of 1852.)

743. First prize, 15s., Mr. Benjamin Dain, Slade House, Aston, Birmingham.

748. Second ditto, 10s., Mr. Thomas Lowe, Whateley, near Fazeley, Staffordshire.

740. Third ditto, 5s., Mr. David Groom, Burlish, Stourport, Worcester-shire.

Class 34.—SILVER-SPANGLED HAMBURGH.

(For the best Cock and three Hens of any age.)

783. First prize, 1l. 1s., Mr. T. B. Wright, Great Barr, Staffordshire.

780. Second ditto, 15s., Mr. A. F. Sparkes, Bridgnorth, Shropshire.

767. Third ditto, 10s., Mr. William Beach, Vine Inn, Monument Lane, Birmingham.

Class 35.—SILVER-SPANGLED HAMBURGH.

(For the best Cock and three Pullets, Chickens of 1852.)

804. First prize, 15s., Mr. James Whilock, 15, High-street, Birmingham.

787. Second ditto, 10s., Charles Robert Colville, Esq., M.P., Lullington, near Burton-upon-Trent.

816. Third ditto, 5s., Mr. Henry Clapham, Aireworth, near Keighley, Yorkshire.

Class 36.—POLAND FOWL (Black, with White Crests).

(For the best Cock and three Hens of any age.)

828. First prize, 1l. 1s., Mr. Edward Bird Guest, Ivy House, Broadwas, Worcestershire.

825. Second ditto, 15s., Mr. Edward Hewitt, Eden Cottage, Sparkbrook, Birmingham.

823. Third ditto, 10s., Mr. Edward Hewitt, Eden Cottage, Sparkbrook, Birmingham.

Class 37.—POLAND FOWL (Black, with White Crests).

(For the best Cock and three Pullets, Chickens of 1852.)

831. First prize, 15s., Miss Martha Hewitt, Eden Cottage, Sparkbrook, Birmingham.

842. Second ditto, 10s., Mr. Edward Collins, 114, Moland-street, Birmingham.

837. Third ditto, 5s., Mr. Henry Child, jun., Sherbourne Road, Balsall Heath, Birmingham.

Class 38.—POLAND FOWL (Golden, with Ruffs or Beards).

(For the best Cock and three Hens of any age.)

843. First prize, 1l. 1s., Mr. John Edwards Mapplebeck, Highgate, Birmingham.

847. Second ditto, 15s., W. G. Vivian, Esq., Singleton, Glamorganshire.

948. Third ditto, 10s., John Ault, Brailsford, near Derby.

Class 39.—POLAND FOWL (Golden, with Ruffs or Beards).

(For the best Cock and three Pullets, Chickens of 1852.)

850. First prize, 15s., Mr. Daniel J. Fleetwood, 53, Ann-street, Birmingham.

851. Second ditto, 10s., Mr. John Edwards Mapplebeck, Highgate, Birmingham.

857. Third ditto, 5s., Master Godfrey Horner, Charlotte-street, Hull.

Class 40.—POLAND FOWL (Golden, without Ruffs or Beards).

(For the best Cock and three Hens of any age.)

861. First prize, 1l. 1s., Mr. William Cox, Brailsford Hall, near Derby.

862. Second ditto, 15s., James Winter, Brailsford, Derbyshire.

858. Third ditto, 10s., Mr. William Cox, Brailsford Hall, near Derby.

Class 41.—POLAND FOWL (Golden, without Ruffs or Beards).

(For the best Cock and three Pullets, Chickens of 1852.)

863. First prize, 15s., Mr. Edward Farmer, Greet, Sparkbrook, near Birmingham.

867. Second ditto, 10s., Mr. Edward Farmer, Greet, Sparkbrook, near Birmingham.

No third prize.

Class 42.—POLAND FOWL (Silver, with Ruffs or Beards).

(For the best Cock and three Hens of any age.)

868. First prize, 1l. 1s., W. G. Vivian, Esq., Singleton, Glamorganshire.

871. Second ditto, 15s., John Ault, Brailsford, near Derby.

No third prize.

Class 43.—POLAND FOWL (Silver, with Ruffs or Beards).

(For the best Cock and three Pullets, Chickens of 1852.)

872. First prize, 15s., Mr. Daniel J. Fleetwood, 53, Ann-street, Birmingham.

874. Second ditto, 10s., Master Godfrey Horner, Charlotte-street, Hull.

873. Third ditto, 5s., John Ault, Brailsford, near Derby.

Class 44.—POLAND FOWL (Silver, without Ruffs or Beards).

(For the best Cock and three Hens of any age.)

878. First prize, 1l. 1s., Mr. Theodore Bullock, Hawthorn House, Handsworth.

876. Second ditto, 15s., Mr. Thomas Robson, Heath Hall, near Halifax.

884. Third ditto, 10s., Master Godfrey Horner, Charlotte-street, Hull.

Class 45.—POLAND FOWL (Silver, without Ruffs or Beards).

(For the best Cock and three Pullets, Chickens of 1852.)

887. First prize, 15s., Mr. Thomas Robson, Heath Hall, near Halifax.

886. Second ditto, 10s., Mr. George Parker, Perry Barr, Staffordshire.

No third prize.

Class 46.—FOR ANY OTHER DISTINCT BREED.

CUCKOO.

891. Prize, 1l. 1s., The Right Honourable Lady Guernsey, The Bury, near Leamington.

POLAND.

902. Prize, 15s., W. G. Vivian, Esq., Singleton, Glamorganshire.

RUMPLESS.

905. Prize, 15s., Mr. Thomas Beetenson, Vauxhall Grove, Birmingham.

COCHIN-CHINA.

917. Prize, 15s., John Fairlie, Esq., Cheveley Park, near Newmarket, Cambridgeshire.

923. Prize, 10s., Mr. T. B. Wright, Great Barr, Staffordshire.

FRIZZLED.

924. Prize, 15s., Mr. Theodore Bullock, Hawthorn House, Handsworth.

NEGRO, OR SILKY.

930. Prize, 1l. 1s., Mr. Jonathan Harlow, Moseley, near Birmingham.

ANDALUSIAN.

935. Prize, 15s., Mr. John Taylor, jun., Cressy House, Shepherd's Bush, London.

Class 47.—BANTAMS.

(For the best Cock and two Hens.)

GOLD-LACED.

957. First prize, 15s., Captain Clement Delves Hill, Summerhill, Newport, Shropshire.

953. Second ditto, 10s., Mrs. Hosier Williams, Eaton Mascott, near Shrewsbury.

SILVER-LACED.

983. First prize, 15s., Mr. Thomas Roscoe, Knowsley, near Prescot.

985. Second ditto, 10s., Mr. Edward Hewitt, Eden Cottage, Sparkbrook, near Birmingham.

WHITE.

996. First prize, 15s., Mr. Benjamin Dain, Slade House, Ashton, Birmingham.

994. Second ditto, 10s., Mr. Richard Bratton Baddeley, Wellington, Shropshire.

BLACK.

1005. First prize, 15s., Mr. John Dain, Henley-in-Arden.

1003. Second ditto, 10s., Mr. Matthew Ridgway, Dewsbury.

ANY OTHER VARIETY.

1017. First prize, 15s., Mr. C. Amsden, Lichfield.

No second prize.

Class 48.—PIGEONS.

CARRIER.—1019. First prize, 7s. 6d., Mr. Edward Barber, Monk's Path, Shirley Street, near Birmingham.

1024. Second ditto, 5s., Mr. Samuel Ridley, jun., Brighton.

1026. Commended, Mr. Edward Barber, Monk's Path, Shirley Street, near Birmingham.

ALMOND TUMBLER.—1033. First prize, 7s. 6d., Mr. George Parker, Perry Barr, Staffordshire.

1035. Second ditto, 5s., Mr. William Curtis, High Street, West Bromwich.

- OTHER TUMBLERS.**—1039. First prize, 7s. 6d., Mr. John Percivall, 1, Belgrave Place, Bristol Road, Birmingham.
- OWL.**—1044. First prize, 7s. 6d., Miss Sarah Mary Beetenson, Vauxhall Grove, Birmingham. 1043. Second ditto, 5s., Miss Sarah Mary Beetenson, Vauxhall Grove, Birmingham.
- NUN.**—1046. First prize, 7s. 6d., Mr. Charles Tovey, Waterloo Place, Bloomsbury, Birmingham. 1048. Second ditto, 5s., Mr. Josiah Chune, Coalbrookdale, Shropshire.
- TURBIT.**—1051. First prize, 7s. 6d., Mr. Joshua Hopkins, 39, Dale End, Birmingham.
- JACOBINE.**—1059. First prize, 7s. 6d., Mr. John Amphlet, Walsall. 1057. Second ditto, 5s., Mr. John Dugard, Finch Street, Handsworth.
- FANTAIL.**—1067. First prize, 7s. 6d., Mr. Thomas Beetenson, Vauxhall Grove, Birmingham. 1068. Second ditto, 5s., Mr. James Steen Harvey, 34, Aston Street, Birmingham.
- TRUMPETER.**—1076. First prize, 7s. 6d., Mr. Joshua Hopkins, 39, Dale End, Birmingham. 1074. Second ditto, 5s., Mr. W. H. Goddard, Hagley Road, Edgbaston.
- POUTER, OR CROPPER.**—1079. First prize, 7s. 6d., Mr. William Curtis, High Street, West Bromwich.
- BARBE.**—1083. First prize, 7s. 6d., Mr. Joshua Hopkins, 39, Dale End, Birmingham.
- RUNT.**—1089. First prize, 7s. 6d., Mr. George C. Adkins, Edgbaston. 1086. Second ditto, 5s., Mr. John Hill, Vincent Street, Balsall Heath.
- DRAGON.**—1097. First prize, 7s. 6d., Mr. Samuel Ridley, jun., Brighton. 1095. Second ditto, 5s., Mr. Edward Barber, Monk's Path, Shirley Street.
- OTHER VARIETIES.**—No prizes awarded.

Class 49.—GEESE.

1120. First prize, 1l. 1s., Mrs. H. Hill, New House, Stretton Grandison, Herefordshire. 1107. Second ditto, 10s., Mr. John Taylor, jun., Cressy House, Shepherd's Bush, London. 1119. Third ditto 5s., Thomas Townley Parker, Esq., Sutton Grange, St. Helen's, Lancashire.

Class 50.—DUCKS.

- AYLESBURY.**—1127. First prize, 1l. 1s., The Right Honourable Viscount Hill, Hawkstone, Salop. 1137. Second ditto, 10s., Miss Rachel Walker, Clipston Rectory, Northamptonshire. 1148. Third ditto, 5s., Mr. Joseph Jennens, Moseley, near Birmingham. The class generally commended.
- ROVEN.**—1167. First prize, 1l. 1s., Mr. Charles Punchard, Blunt's Hall, Haverhill, Suffolk. 1164. Second ditto, 10s., Mr. H. Worrall, Knotty Ash House, near Liverpool. No third prize.
- ANY OTHER VARIETIES.**—1172. First prize, 1l. 1s., Miss Clifton, Whittington, near Worcester. 1173. Second ditto, 10s., Sir John Cathcart, Bart., Cooper's Hill, Chertsey, Surrey. 1175. Third ditto, 5s., Mr. John Shackel, Blenheim House, Small Heath, near Birmingham.
- MUSCOVY.**—1184. Prize, 10s., Mr. Thomas Snape Tunaley, Milfield, near Tamworth.

Class 51.—TURKEYS.

1217. First prize, 1l. 1s., John Fairlie, Esq., Cheveley Park, near Newmarket, Cambridgeshire. 1211. Second ditto, 10s., Mr. William Udal, Green Lanes, near Birmingham. 1196. Third ditto, 7s. 6d., The Right Honourable the Countess Howe, Gopsall Hall. The class generally good.

Class 52.—GUINEA FOWL.

1220. First prize, 1l. 1s., Mr. William Masfen, Norton Caines, near Cannock. No second prize.

Judges of Poultry.—The Hon. and Rev. Stephen Willoughby Lawley, Escrick Rectory, near York; G. R. Andrews, Esq. Dorchester; The Rev. Robert Pulleine, the Rectory, Kirby Wiske, near Thirsk; Mr. John Baily, Mount-street, Grosvenor-square, London.

Judges of Pigeons.—Mr. T. L. Parker, Birmingham; Mr. Hale, Handsworth.

DISEASES OF POULTRY.—No. 2

BROKEN LIMBS.

In accordance with your desire, I shall be happy to investigate, as far as my opportunities will allow, the various diseases of poultry. I believe that this can only be advantageously done by a close observance of symptoms during life, and an attentive examination after death. Situated as I am, with but a small number of fowls, and those in circumstances calculated to promote health, I am not likely to have, from my own stock, many subjects for investigation; I should, therefore, feel obliged to any of your readers who would supply me with patients as soon as I can make the requisite arrangements for opening my poultry hospital. I must beg of them, however, to follow the usual course in such cases, viz., to send me a letter of introduction previously, otherwise their protégés might arrive when the wards were overflowing, and all the beds in the hospital occupied. This would be more especially requisite, as, in any contagious diseases, it would be important, in the highest degree, to keep the birds separate. Should the patients die, I should make *post mortem* examination in

every case. On the contrary, should they recover under the treatment pursued, I should be most happy to return them to their owners.

In the meantime, I may say a few words respecting the treatment of broken bones. Fractures of the bones of the body are less likely to occur in birds than in other animals, inasmuch as the framework of the body is more completely united together, and is protected from injury by the feathers. In cases where fracture of the ribs, or other bones, may be suspected, there would be great difficulty in determining the nature of the injury, and I do not think anything more could be done than keeping the bird quiet until recovery.

In cases of broken wings, the quill feathers would prevent any recourse being had to ordinary bandaging. The plan I should pursue, would be to tie carefully the ends of some of the quills together in *their natural position*, with the wing closed; this would prevent motion of the broken ends of the bones; and to keep the bird in an empty place, where there could be no perch, or other substance, for it to attempt to fly upon.

Fracture of the fleshy part of the leg would be less manageable, and I can hardly recommend any bandaging that would be readily applied. The most common fracture in fowls is that of the naked part of the leg. This is usually treated by wrapping a slip of rag round the injured limb, and tying it with thread—a very imperfect plan, as motion of the broken bones is not prevented, and which is, therefore, frequently unsuccessful in its results. I should recommend a modification of what is known to surgeons as a gum splint. Let the white of an egg be well-beaten up with a fork, and spread upon a strip of thick, soft, brown paper, as wide as can be conveniently wrapped around the broken limb. The fowl should be held by an assistant; the leg slightly stretched, so as to bring the ends of the bones in a straight line; the moistened paper should be wrapped smoothly round several times, and secured by two or three turns of thread; and, lastly, to prevent the parts being moved before the paper has become dry and stiff, a thin splint of wood, such as is used for lighting pipes, may be bound with thread on each side; the wood might be removed the following day, as it then would add only to the weight, without increasing the advantage of the contrivance, which acts by preventing all motion, and so places the limb in the best possible condition for a union to take place.

Splints of this kind are of great value in human surgery, and several modifications of them exist; they are sometimes formed of gutta percha, softened by heat, or by leather, softened by hot water, or by tow and gum, lint and starch, &c.; but I do not think any so applicable to poultry as I have recommended, as the materials are always at hand, and, what is a matter of great importance, can be applied immediately after the accident.—W. B. TEXETMEIER, *Tottenham, Middlesex.*

HARDIHOOD OF PLANTS AT CLOYNE, IN IRELAND.

MANY thanks for your information relative to *Veronica speciosa*. My plant of it is but a rooted cutting of July last; but, a fortnight since, I saw the parent plant in full luxuriance, in front of a south wall, in a garden near Kilmallock, in the county Limerick, and without any protection whatever. Is *Veronica Jacquini* delicata similarly hardy, as I have a small plant out? [*Yes*] *decussata* I know is not.

It may interest you to know what plants are still (Dec. 6th) standing in good health out-of-doors here, at least, in my small garden—*Salvia fulgens* and *Grahamii*. The *Patens*, also, has not yet died down. *Escallonia rubra*, *Lophospermum*, and *Calumbilis scabra* (the latter has borne so much seed that I would gladly exchange it with any one who wished for it); a mixed bed of *Verbenas*, principally scarlet (*Defiance*), also seem in great strength; and near them some *Alosoas* and *Cupheas*. The *Ixias* and scarlet *Gladioli* are all springing up. The *Calla Æthiopica* is in great luxuriance, from the recent rains.—REV. R. M. E.

VISITS TO SOME OF THE CHIEF POULTRY YARDS IN ENGLAND.—No. 5.

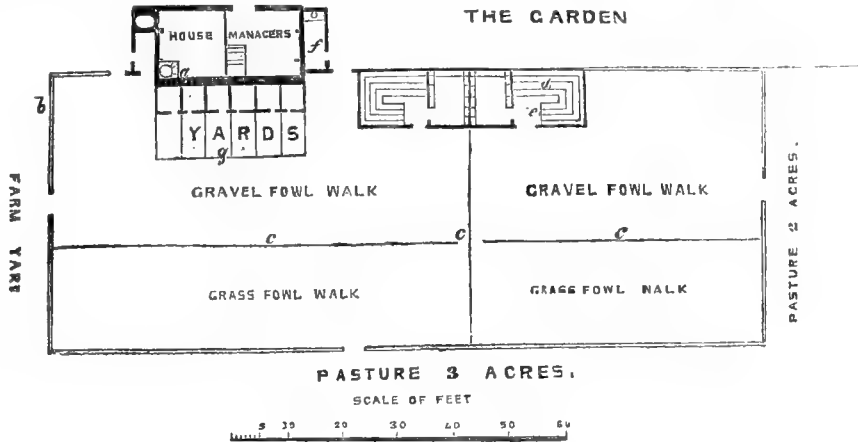

(MR. PUNCHARD'S.)

"BLUNT'S HALL," the hospitable residence of Mr. Punchard, is situated at the extreme western part of the county of Suffolk, about a mile from the little market town of Haverhill, once famed for its manufactory of checks, cottons, and fustians.

For his poultry, Mr. Punchard has two establishments, one at Blunt's Hall, and another at an off-farm, at about half-a-mile distant. The accommodation afforded the poultry in each place is much the same. Mr. Punchard confines himself entirely to two kinds, namely, Cochins, and Ducks of the Rouen and Aylesbury breed. Of the Cochins,

or Shanghaes, by which name, I suppose, we shall soon be obliged to distinguish them, he has from about five to six hundred, all of the purest breed, bred by himself, and chiefly, I believe, from imported birds. In a corner, I observed a few pairs, very recently from Shanghai, which he has not yet had time to breed from. In respect to colour, the different shades of buff very much preponderate over the brown and partridge; but, in my opinion, breeders have dwelt too much on colour, the brown and partridge being less esteemed, but, as far as my experience has led me, they are the largest birds, and produce the greatest weight of eggs.

The accompanying sketch will serve to give a pretty correct idea of the accommodation afforded by Mr. Punchard to his fowls, and may be interesting to many of the readers of *THE COTTAGE GARDENER*.

- a This copper heats the chicken houses by hot-water pipes during the winter, which can be extended to the roost and nest houses.
- b Wall four feet high.
- c Wire fence three feet high.
- d Perches arranged in a sloping form.
- e Windows running on cast-iron rollers, the openings being wired inside to admit air at pleasure.
- f Ventilators with moveable louvre boarding. A perforated zinc tube from each end of the building communicates with the ventilator and gives any degree of coolness. In winter they are closed. The roof of this building is slate nailed on boarding.
- g Space pale fencing.

As regards feeding, I observed that the fowls are never without a supply of food, which consists of a mixture of wheat, crushed barley, and peas. The feeding-troughs are upon the same principle as the hopper of a mill. The trough itself is five feet long, and three or four inches deep, and, as the fowls take the food from the trough, it is supplied from a reservoir above, which holds two or three bushels, the supply being alike on both sides, making together a length of ten feet in each feeder. Fresh water is supplied to them every morning in Bailey's registered fountains. An air of the most perfect cleanliness pervades every part of the above; the sleeping-places being cleaned out every morning, and fresh dry gravel or sand strewed upon the floors. Considering the very great attention given by Mr. Punchard in selecting his fowls for breeding, I need hardly say, that their progeny is first-rate, and that amongst the brown and partridge, as well as the buffs, there are a number of birds of exquisite symmetry and form. And in this I am borne out by the opinion of a gentleman from the west of England, who is one of our greatest amateur breeders, whom I consider myself most fortunate in meeting at Blunt's Hall. The birds, about two hundred in number, selected by Mr. Punchard for his forthcoming auction, which I hear will take place on Tuesday, the 4th of January, at Mr. Stevens's Great-room, King-street, Covent-garden, are, as a whole, a selection of a very choice and superior kind.—J. H. P.

[Another excellent judge of poultry has also favoured us with the following notes upon Mr. Punchard's poultry establishment.]

Many, in Mr. Punchard's situation, would have been content with the laurels won at Birmingham in 1850, and thought but little of acquiring other Shanghai stock beyond what had been so triumphant on that occasion. Not so with him, however; for, carrying out the true principles on which alone excellence in poultry, or any other stock, can be maintained, several importations of fresh birds from the northern parts of China have been selected for him by

intelligent correspondents, and been added to his collection at Blunt's Hall.

"An imported bird" is now a common term, especially in advertisements, to denote some specimen of new and great excellence, and of increased value. The accuracy of this we greatly doubt; for, hitherto, no recently-imported specimen has come before us equal to the occupants of many a pen at any of our recent exhibitions. Mr. Sturgeon's observations led to the same conclusions as we have ourselves formed, from what has happened in Mr. Punchard's, and some other cases. It is precisely the same with other fowls, and with Spanish, perhaps, particularly; for we know of more than one instance wherein poultry-keepers, desiring to shine with especial lustre in that beautiful class, have had large consignments from Spain, at considerable cost, without in the remotest degree increasing their chances of success. Whether Europe or Asia be their locality, the habits of poultry are identical, and mongrelism is found predominant. How zealously do we guard against it in our own well-wired yards; and how needful is our watchfulness. Thus, wherever similar precautions are altogether neglected, we must always have a large number to select from, where purity of race, and excellence in colour and form, are the objects of our ambition: and not even then must we calculate on success.

Mr. Punchard, therefore, deserves our best thanks for continuing what becomes a very expensive, however necessary a practice; for, if one bird in twelve possesses points of sufficient merit to warrant its introduction into our yard, the cost of the other eleven must be added, and this is, probably, a favourable estimate. We can only hope, therefore, that the now rapidly-increasing numbers of poultry-keepers will have the sound sense and discretion to select stocks from such a source as Mr. Punchard's, and of those other breeders who, like him, disregard cost, that the most perfect specimens of the Shanghai breed, from their native country, may gradually effect improvement in those few points, where the best English-bred birds may be

thought capable of it. If any be bold enough to say, we can have nothing better than some of those birds that have been shown in the course of the present year, we will not argue with him on what must be, as yet, an open question; but only add, that we must, for a time at least, import, that what we now have may be maintained at its present pitch of excellence, and suffer no deterioration. Some chicks of a week old had been hatched from those last imported; their downy covering varied in every tint from brown to white; and if, in spite of Mr. Punchard's care, a Suffolk winter checks their growth, they will be a useful guide for the matrimonial projects of next spring. A cock and hen were here of dark Vandyke brown, almost a self-colour, so far, at least, as we could judge, the birds being in severe moult; in lighter birds, the imported specimens, both here and elsewhere, have generally somewhat more of mottling than is commonly liked. A bamboo coop, in the corner of the yard, was their residence during the voyage; it must have been a narrow residence, and far from convenient. Importers would do well to insist on coops of sufficient height to allow the birds full room to stand upright; and the bars on which they stand should always be parallel to the front. How otherwise they escape deformity in the feet is a matter of wonder.

In one of Mr. Punchard's yards, eighty-five cockerels, in another sixty-five, produced a perfect blaze of colour, from which every tint might be selected. The birds were in admirable condition, and did full justice to the liberality that had awarded them so comfortable an abode, and so liberal a diet; but our eye searches in vain for the beautiful bird that was shown at Winchester; for his rich golden hackle, and glowing buff body colour, no less than his form and carriage, however closely imitated, is not fully attained by any of his relations now before us. We must find him, however, and Mr. Punchard kindly takes us where he appears in company with sundry brothers and cousins, each in a separate basket. Do you ask why? We will tell you. They are undergoing the penance for having appeared in public; for, however peaceable and contented their eighty-five relations may live together, whenever any of them are separated, though only for a few days, their return does not seem anyways pleasing to those who have not enjoyed the same excursion, and the admiration of the public; and this dissatisfaction is sometimes forcibly illustrated.

Mr. Punchard's name is often exclusively associated with the partridge-coloured birds that he has brought to such excellence; but, desiring to have the Shanghae race fully represented in every branch, his yard now numbers specimens of the fawn and buff birds that would do credit to the most skilful breeding. As regards the former, we might search in vain for better than those shown by Mr. Punchard at Winchester, and destined, we hope, for a similar victory at Birmingham. Mr. Punchard's arrangement of the yards and poultry is on a large scale, and most complete in all its detail; for, besides the gravelled court, each lot has the run of a young shrubbery and an acre or so of pasture. Fowls, indeed, were never better housed and cared for in all their wants. Were we lucky enough to have the same conveniences for our birds, we should make but one alteration, and that would be doing away with brick floors, which retain moisture, and consequently lower the temperature, and substitute the chalk, which is abundant in the neighbourhood. The advantage of grinding a large portion of the corn used for the fowls is here evidenced in a striking manner; and Mr. Punchard having a mill attached to his farm is, doubtless, enabled to practice such judicious economy in respect of feeding as the possession of a flock of upwards of six hundred birds must render necessary.

The aspect of the site of Mr. Punchard's different poultry yards and houses was against him; but admirably has he remedied this objection: and a Newmarket racing-stable can hardly boast of more considerations for the wants, and more caution for the health of its inmates, than are evinced in the plan and execution of his poultry buildings at Blunt's Hall.

The kindness of Mr. Punchard, in affording the fullest information on every point to all inquirers, must have led many to profit by his hospitality and experience. And as a large portion of his present stock are destined for the

auctioneer's hammer, not only those who have already seen for themselves, but poultry-keepers of every degree, will do well to take that opportunity of ascertaining how far their own favourites may be benefited by the introduction of his stock.—W.

THE BRISTOL POULTRY SHOW.

THERE are too many proofs to admit of a doubt that the public interest in Poultry is extending and increasing, and not the least of them is that the Exhibitions, hitherto confined to the north of England, almost exclusively, are now becoming general. The Bristol Agricultural Society, like many others, this year added a Poultry Show to their annual Exhibition of other Stock. The show was held on the 6th, 7th, and 8th of December, in a large and commodious room in Partwall Lane, part of the agricultural implement manufactory of Messrs. Fowler and Fry.

The number of pens entered for competition was 295; and when the excellence of many of the specimens, and the short notice given of the show, together with the fact that it precedes that at Birmingham by only one week, are taken into account, we are sure that the Committee and their excellent Secretary, Mr. Marmont, have no reason to regret the conclusion to which they came, to add this new feature to their annual exhibition. The number and respectability of the company, also, showed that they had not been mistaken in supposing that such an addition would prove attractive, and we hope it will turn out remunerative to the funds of the Society.

Our notice of each class must, of course, be short. Taking them in the order of the prize list (we hope the Committee will venture upon printing a catalogue next year), the Spanish first claim our attention, but with the exception of the pen for which the prize was adjudged to Joseph Rake, Esq., there was nothing particular to notice in this class. The Dorkings were a better class, and the pen for which the first prize was awarded to Miss Anne Wilcox were very good birds. The Cochins were the next, and decidedly the best class in the exhibition; the buff preponderating, both in number and quality, although there were two or three pens of very fine white breeds. Of this variety fifty-five pens were entered in class 3, and if we may judge from them of what is likely to be shown in the corresponding classes at Birmingham, the judges there will have no sinecure. Here, at all events, they had no easy task, and there can be no doubt that Cochins are the favourite fowl in the West of England. The first prize was awarded, after much consideration, to Mr. James Pond, of Bath, and the second and third to T. H. Potts, Esq., of Kingswood House. Several other pens were highly commended by the judges. We were sorry again to see the Malays wanting—one pen only being shown, and these not sufficiently good, in the opinion of the judges, to merit a prize. There were fourteen pens of Game Fowl, nearly all good, the principal prize being carried off by P. W. S. Miles, Esq. The Hamburgs were not particularly good as a class, but a few fair specimens were shown, and there was a good pen of Golden-headed Polands. Of the cross-breeds we will only say that we hope they will be excluded from all future shows, both of this and every other Society. The little Golden Bantams mustered strong, but we have seen better birds; while of the Silver variety not a single pen appeared. Some good white ones were exhibited, but the blacks were very poor. The Cochinchina Chickens were equally as good as the adult class, and out of eighteen pens, Mr. Punchard carried off the first and second prizes, the third falling to the share of Mr. Pond. We should ourselves be glad to see the different Societies adopt uniformly a rule, that chickens only should be shown against chickens, and old birds against old birds, and we are very sure such an arrangement would save much trouble to the judges, and render their decisions more satisfactory to themselves and to the public. There was a class here for "any breed," in which Mr. Potts was again successful in winning a first prize for a nice uniform pen of young Cochinchina Chickens. The Geese were but middling. The Turkeys better; and the Ducks, in which latter class Miss Wilcox was again the winner, good. The Pigeons, also, were choice, but few; and a pair of fowl marked "Ceylon Jungle," were quite new to us, and very pretty, as well as very distinct.

We are not aware that the other classes require any special notice, but we cannot conclude without adding a hope that the success of the Exhibition, as a whole, and the interest which it evidently excited, will induce the Committee to repeat it in subsequent years, and that they will (as, indeed, they begun this year by doing) take care to avoid the very objectionable practice of appointing dealers to be judges. Upon this occasion, that not very enviable office was filled by Mr. Bissell, of Birmingham, and Mr. Bond, of Leeds. The prize list was as follows:—

Class 1.—SPANISH.

First Prize to Joseph Rake, Esq. No other prize awarded.

Class 2.—DORKINGS.

First Prize to Mrs. Anne Wilcox. Second, Mrs. Neville.

Class 3.—COCHINS.

First Prize, Mr. James Pond. Second and Third, T. H. Potts, Esq. The judges highly commended pens belonging to Joseph Rake, Esq.; John R. Rodhard, Esq.; William Plummer, Esq.; Mr. C. Punchedard, and John Abraham, Esq.; and commended pens shown by Henry L. Bean Esq.; T. H. Potts, Esq., and Mr. James Pond.

Class 5.—GAME.

First Prize, P. W. S. Miles, Esq. Second, Mr. Thomas Smith.

Class 6.—PENCILLED HAMBURGH.

We omitted to note the prizes in this class.

Class 7.—SPANGLED HAMBURGH.

First Prize, Charles Greig, Esq. Second, Mr. Charles Edwards.

Class 8.—POLANDS.

First Prize, R. L. Bush, Esq. Second, Mr. C. J. Kenning.

Class 9.—CROSS BREED.

First Prize, Mr. James Pond. Second, Mr. John Brackenridge. Third, Mr. Henry S. Pigott.

Class 10.—CUCKOO.

No First Prize. Second, John Bumble.

Class 11.—GOLD AND SILVER BANTAMS.

First Prize, Mr. John R. Rodband. Second, Mr. Thomas Canning.

Class 12.—WHITE BANTAMS.

First Prize, Mr. G. T. Hodson. Second, Mr. Henry L. Bean. Highly commended, Mr. G. T. Hodson. Commended, Mr. John R. Rodband.

Class 14.—COCHIN CHICKENS.

First and Second Prizes, Mr. Charles Punchedard. Third, Mr. James Pond. Commended, Brooke Smith, Esq. (two pens). Highly commended, G. C. Atkins, Esq.

Class 15.—ANY BREED.

First Prize, Mr. Thomas Potts. Second, Mr. Joseph Rake.

Class 16.—TURKEYS.

First Prize, Mr. John Hill. Second, J. R. Rodbard, Esq. Third, Dr. Washbrough.

Class 17.—GEESE.

First Prize, Henry Orum.

Class 18.—DUCKS.

First Prize, Miss Wilcox, (Aylesbury). Second, John Miles, Esq., (Aylesbury). Third, Mr. C. Punchedard (Rouen).

Class 19.—GUINEA FOWL.

First Prize, John R. Rodbard, Esq. Second, Daniel Burgess, jun., Esq.

Class 20.—PIGEONS.

Carriers, Mr. William Martin (the whole class commended). Classes, 21, Antwerps; 22, Barbs; 23, Croppers; 24, Runts; 25, Fantails; 26, Jacobins; 27, Turbets; 28, Nuns; 29, Archangels; 30, Trumpeters; 31, Almond Tumblers, all to G. C. Atkins, Esq., whose birds were beautiful, and shown in excellent condition.

TO CORRESPONDENTS.

HITCHIN POULTRY SHOW.—When we first glanced over a letter addressed to us by *One of the Committee of the Hitchin Poultry Show*, replying to our comment on such shows being held for the benefit of inn-keepers, we did not observe this postscript—"Is it possible you are a disappointed exhibitor?" We pass over the impertinence of this to reply, though scarcely necessary, that we did not exhibit directly or indirectly at Hitchin. Let us add, for the improvement of our correspondent's self-knowledge, that he who is hasty in attributing an ill-motive to another, should examine closely whether he himself would be actuated by the evil he suspects. The other portions of the letter, written temperately enough, leave our opinion unaltered—that no Poultry Show, should, if avoidable, be held in connection with an inn. The reasons against it are too numerous, and too apparent, to need detailing; and we are too anxious for the success of all Poultry Shows not to point out whatever we consider prejudicial to them.

PREVENTING A HEN SITTING.—"As a breeder of Cochins, I have been plagued by their propensity to sit; and I have found the following very good plans for breaking them of that propensity, which, as at this time of the year parties do not want sitting-hens, may be useful to some of your readers. The first way is, when you notice them at all getting broody, which is easily told by their staying longer than usual on the nest when laying, and the quarrelsome disposition they acquire just at that time,

to remove them to another walk, or put them in a coop, and, if possible, let them be removed before they have laid their last egg, or got fond of the nest, and in a few days they will have settled down, and the inclination to sit have gone off. The other plan is, instead of letting them sit on an empty nest for three weeks, and in two cases out of three finding them as bad to break of sitting as they were the first day, if not worse, let them have two or three good eggs to sit upon; they then hatch a chick or two, and they will naturally, in a day or two after hatching, leave the nest with the chickens; let them have them a day or two to roam about with, then take them away. The hen, in a few hours, will forget her offspring, and with them her inclination to sit. The chickens, if three or four lots, may be given to one hen, or disposed of in any other way parties may think proper."—T. B. STEAD.

ORCHID-CULTURE (W. S.).—All orchids should go to rest when they have completed their growth. Your *Oncidium papilio* may continue blooming. Do not, at any time, cut down the flowering-stem till it dies naturally. Your *Aerides odoratu*, a foot high, will most likely bloom next year; it is evergreen. *Zygopetalum Mackayi*, just blooming, must have a little water, and be kept growing. It is a winter-blooming species. *Dendrobium nobile*, two feet high, if the shoots are strong and well-ripened, should flower next year; let it now go to rest. It partially loses its leaves; let it remain in the present pot till it begins to grow. The *Aerides* would do best in a rough basket, filled with sphagnum moss only, and hung up to the rafter, about three feet from the glass. The heat you give them is quite right. Your *Cattleya mossia* is evergreen, and should be grown at the coldest end of your house; let it remain in its present pot till spring. Orchids will do in a mixed plant stove, but should be placed at one end, where they can have the proper treatment. See THE COTTAGE GARDENER for 1850 and 1851, for full information on Orchid-culture.

SPECIMEN PLANTS FOR A GREEN BANK (Mrs. C.).—We think we have seen the very banks you mention, and the waters also, but it was "long ago." More recently, we had some delightful rambles along these rivers with the late Sir Thomas Dick Lauder, in his last efforts at painting the beautiful scenery in those parts. On the highest part of the banks we would plant a group of three or four Venetian Sumachs (*Rhus cotinus*), about four feet apart each way; and in four years they will look as one, and "make one grand specimen," as the gardener says. The flowers are charming, and they hold on a long time; but this is not an evergreen. The trees you mention—*Pinus insignis*, *Abies Douglassii*, and *Cupressus funebris*, or Chinese Cypress, as you call it—you will, probably, have to send to Edinburgh for. For such sized plants as would suit you, about 5s. each would be a fair price. The Sumachs at 1s. would do. If you have room enough, you ought to have a *Dendur* at 6s.; an *Auracaria imbricata*, about the same; and *Cupressus macrocarpa* and *C. Goveniana*, for 5s. or 6s. the two; and see you allow them as much room as you can spare, and do not plant them too near to the house.

WHEAT DIBBLER.—We have been favoured with the following replies:—"In answer to 'T. R. N.,' the best dibbles for making the holes and delivering the seed at the sowing-time is Newberry's (Newington's?). The construction of this machine is perfectly beautiful, and wonderfully effective. It may be had for one, two, three, four, or five rows, and will sow a proportionate number of acres in the day. It delivers from one to three, and sometimes five, grains in each hole, at the rate, the *abundant rate*, of one bushel to the acre. The crop looks in March like a field of green shaving-brushes: such beautiful tufts of plants so equally distributed. Upon land well-drained, fallowed, and enriched, six quarters per acre may be calculated upon. The sowing should take place on the furrow-slice, just mellow, but not too free, or at all harrowed, lest the holes be stopped by the adhesion of the soil. We speak of that we know; for we have not only heard of, or seen, but possessed, used, and felt the benefit of this dibble. The seed time should be rather early, as this deep depository does not admit of the plant coming up so rapidly as in shallow sowing. The pressed *nidus* for the seed gives admirable ground-hold to the plants. It has been objected, that the seed-hole forms a dangerous cup for the detention of water. We can only hope that land will be generally drained, when this objection will not lie, or be mentioned. It is a wonderful invention which can render undrained land worse than it is, especially for wheat.—T. BETA." A *Florist* says:—"I see your correspondent, 'J. R. N.,' wishes to know which is the best 'wheat-dibbling machine.' I believe the one invented by Mr. Gillam, of the Bear Hotel, Woodstock, Oxon, is the best. You will find it in the Exhibition catalogue; and I believe it is there recommended, and I know it to be used by many persons around here (Oxford); but by writing to Mr. Gillam, I have no doubt he will send him every information."

GRAPE-GROWING.—Mr. W. Dobson says:—"I have frequently been asked where the best forced grapes grew, that is, within three or four miles of any large town in England? I have been at most of the places round the largest towns in England. My opinion is, that the best grapes are near the town of Leeds, in Yorkshire, where I am staying at the present time. The best near Leeds, last autumn, were in the following gentlemen's gardens, which, I think, could not be beaten near any other town—Sir G. Goodman, M.P., Mrs. Benyon, G. O. March, Esq., —Donesthorp, Esq., John Wilkinson, Esq. These are all near Leeds, and nearly all single-handed places, but far too much work for one man. If Mr. March's gardener would send you a few lines stating how he manages to grow both Peaches and Grapes together, it would be useful to the readers of THE COTTAGE GARDENER, for those fruits are managed in a first-rate manner." It is very difficult to grow Grapes and Peaches in the same house; and if Mr. March's gardener will favour us with his mode of treatment, he will oblige us and many of our readers.

WORKS ON PEACH AND STRAWBERRY (C. Jones).—You will find these in "The Gardeners' Monthly Volume," and they may be had of Mr. Bohn, Bookseller, London.

WHOSE SHANGHAE FOWLS ARE UNRELATED? (H.).—You are quite right in being anxious to breed from birds not of the same strain; and you are equally correct in saying it is difficult to know which are not so. All that you can do is to inquire of the sellers what is the parentage of their birds, and regulate your purchases accordingly. It is quite true, as you state, that Mr. Punchedard had his stock originally from Mr. Sturgeon, but they are quite a distinct strain, and both of them have added

imported birds to their stock, so as to have quite distinct blood. The same observation applies to our own, and many other breeders of Shanghai Fowls; their stocks originally came from some well-known yards, but have been mingled with imported birds, so as to have chickens of a strain that might be coupled, unobjectionably, with chickens from the original stock.

VINERY (*An old Subscriber*).—Sanders's *Treatise on the Culture of the Vine* will, perhaps, suit you.

WOODLARK (*Delitick*).—A warm greenhouse would not suit this bird.

DORKING COCK (*Curalonluch*).—We cannot give you the information. Put in a short advertisement, and you will have abundance of answers.

DAMP-WALLS (*M. S.*).—To prevent damp penetrating, if the smell be not objectionable, paint them over thickly with coal-tar, and dust quicklime thickly upon it. It will form an asphaltic covering.

ROSE-TREE LABELS (*Zero*).—Mr. Ivison obligingly informs us, that the labels you admired at Syon House Gardens, were made by Messrs. Morrells, 149, Fleet-street, London.

HARDENBERGIA MONOPHYLLA (*Evergreen*).—As the young growth is green and healthy you have no reason to be alarmed, though numbers of the old leaves turn pale and fall off. This is just the method that nature takes to relieve herself from useless appendages in the case of evergreen and semi-evergreen plants. When this, in the case of the *Hardenbergia*, takes place to an undue excess, it is generally attributable to dryness at the roots, a sour soil, owing to want of drainage, or a low, foggy temperature. The weather has not been so cold as to demand much fire on that account; but it has been so dull and misty, that a sharp fire in the morning would do great good by creating a rapid circulation of air. Our impression is, that you will find your plant all right, and very beautiful a few months after this.

WINTERING PLANTS.—*An Amateur Geranium-grower*, having a deep wooden frame, surrounded by a wall of turves, with wood platform to keep the plants near the glass, asks—"Can I keep Geraniums, Fuchsias, Calceolarias, Verbenas, and Auriculas, over the winter, by throwing a strong, double mat over the glass at night, and giving air at back in fine days? will extra heat be necessary, or will that of oil lamps do?" See Mr. Fish's article of last week, and somewhat similar ones of last year. Your platform for the plants, and a turf wall round the boards, are capital: could you not make the latter waterproof? Your double mats will be quite sufficient for moderate frosts; but if your plants have been growing, or there is likely to be a frost above 7° or 8°, you would require to place some non-conducting material, such as hay or straw, between them. If you would study neatness, and your own personal comfort, have a waterproofed covering. A few large earthenware bottles, filled with hot water, would be the simplest mode of communicating heat; but if your object is merely to preserve the plants during the winter, the bottles will not be so useful for communicating heat as in causing a circulation of air in muggy weather. In such a pit as yours, it is always advisable to have a bundle of dry litter ready to throw over the glass in any sudden emergency. We think we have previously told how a nurseryman, with a small supply of litter, saved his pits of Mignonette, while most of his neighbours lost their stock. During the whole night, he moved, and shook, and turned the scanty litter. He knew all about the radiation of heat.

FLOWER-GARDENS (*S. S.*).—Your own planting will be noticed when the plan is engraved. (*Caen*).—You mistook the thing altogether, and broke the rules throughout. We plant, or, rather, suggest the planting of such plans as we publish monthly; but we only criticize, or give opinions on the planting of such other plans as are sent to us. The same reply applies to *O. J. B.*, and we must keep to our rules.

MELON SEED (*Verax*).—Any age above four years does not improve Melon seeds, and might be injurious to some varieties; but there have been no direct experiments we know of to prove this.

CUTTING-DOWN LAURELS (*Ibid*).—Whoever said that Laurels cut between November and May would get their young shoots destroyed by frost must have been dreaming. Such Laurels do not make young shoots so early, by some weeks, as Laurels not touched. Laurels cut hard-in in March have not the slightest advantage over Laurels cut any day from the end of September to the 1st of May. We have done it, or helped to do it, all these months for many years; and if we were to begin life to-morrow as a Laurel-planter or grower, we would cut down our Laurels any time during the rest season that suited our convenience. The *Laurustinus* is not a Laurel, but a Viburnum, and, on account of its flowering, is seldom cut till late in May; but it, also, and all our hardy evergreens, may be cut any day during the winter. There has been more than philosophy about them for ages, which wants reconsidering.

BANKS OF A RIVER (*R. J. L.*).—Were it not for the overflowing of the river, all the herbaceous plants that would grow in your garden, or in your neighbouring wood, would do on these banks, notwithstanding water does stand at eighteen inches from the surface. *Epilobiums*, *Lythrum*, *Calltha palustris*, Single and Double *Trollius*, *Pæonies*, most of the hardy *Lilies*, and such things will answer. Then, as to shrubs, Cut-leaved *Alders*, almost all the *Willows* and *Poplars*, with the whole breed of *Magnolias*, and most *Rhododendrons*, deciduous *Cypress*, *Snow-drop-tree*, *Box-tree*, *Aucuba*, and common *Laurel*, will do.

UNPRUNED GERANIUMS (*Fiddlestick*).—Your Geraniums were neglected to be cut down at the proper time, and are now offering to make bottom shoots. Let them be as they are to the end of January, then cut them down to their bottom eyes, and about the middle or end of February shake one half of the ball from the roots, no more, and put them in the same pots, with a little rich soil all round; a month after that give them a good shift, and you never had better bloom or finer plants than you will have next summer; that is, because you never had a good bloom of them before: those who neglect to cut them at the right time never do.

MUSHROOMS (*E. S.*).—We have never seen nor heard of raising Mushrooms artificially on lawns, or grass fields, but we have seen fine crops of Mushrooms come up between rows of potatoes, from using old dung from spent mushroom beds to enrich the ground. We have also seen similar crops from spawning at the time of planting the potatoes. You might easily, and at very little expense, inoculate your lawn with some best spawn, and be the first to prove the experiment. Spawn your grass next May; and in August, if the weather is dry, give them a heavy watering

once a week, and let us know the result. If you have access to old mushroom beds, you might dress your lawn next February, March, or April, with half spent dung and half coal-ashes, and that might impregnate the turf with spawn. But you probably know as much about the subject as any one else.

SHADED BORDER (*R. A.*).—Trench it three feet deep, and to within one foot of the stems of the Laurels; then plant a row of White Lilies (*Lilium candidum*) at thirty inches from the hedge; and then a row of all the kinds of herbaceous *Pæonies* you can get, and here and there in the row, a patch of *Crown Imperials* in variety. In front of that, all the *Narcissus*, and there are upwards of 200 kinds of them—*Snowflakes*, *Leucojums*, a few *Ornithogalums*, and, indeed, any hardy bulbs that will grow to a foot or two feet high; and next the edge, *Crocuses*; nine inches from it, and in front of them, a row of *Snowdrops*, or *Winter Aconite*. Then each season cut down behind the White Lilies as deep as you trenched, to get rid of the Laurel roots.

PYRETHRUMS AND RASPBERRIES (*M. F.*).—You do not say which of the *Pyrethrums* your *Fever-few* is. We suppose of the old double-white. If so, cut it nearly down, and do not disturb yourself farther about it, unless it be a tender kind. These things will go on for years. For your *Raspberries*, throw up beds above the level, and introduce both decayed vegetable matter, of any kind, and sand liberally, securing them that depth above ground that ought not to be obtained below. *Raspberries* detest slow-acting mediums. As to your *Apricots*, "the knowledge of disease being half the cure," we cannot divine anything, as we do not know what may be the conditions.

DISEASED APRICOT (*Topiarius*).—Your Apricot, with one branch shrivelled, is probably rooted deep in an ungenial soil. We would take it up, make a platform, and replant it in sound turfy-loam.

LEGS OF SHANGHAI FOWLS (*A. W. C., Norwood*).—The colour of the legs of these birds is a pale yellow; a little pink down the sides of the legs, and where the scales of the legs and feet are thinnest, is not objectionable.

RAPE AND LNSEED DUST (*Veto*).—If we had this "at command," we should boil it in water, and try it with the meal we give our fowls. We should not buy it for such a purpose, because we do not know what its effect upon poultry may be.

PLANTING FRUIT-TREES (*A Subscriber from the First*).—As your trees are either on a hill, or on the side of a steep slope, let them remain, but have your soil well-drained.

POTATO AND CARROT FAILURE (*Edmund*).—It is very probable that the cause of the two failures was an over-rich soil and a bad season. Trench your ground; plant in February the earliest ripening potato you can obtain, and sow in April Short Horn Carrots, and you will, probably, have better success. A four-gallon stone bottle, filled with boiling water as often as it becomes nearly cold, will keep the frost out of your little greenhouse.

ESPALIER RAIL (*W. Salcombe*).—Having a bar along the top is not at all a novel suggestion. They are made so very commonly both in iron and wood. The suggestion that insects are the cause of the *Potato Murra* was made by Mr. Smee, in 1846, and the suggestion has been repeatedly shewn to be erroneous.

F. W. S.—Your plant is *Diplacus glutinosus*, or Clammy *Diplacus*. **DECAY OF CELERY** (*Ibid*).—The cause of the decay is not from being planted in beds, or so close to each other, but from ripeness, or being too much earthed-up at the last time performing this work; and the soil being heavy, with too much wet. Ripeness, we should say, for certain is the very cause of decay. If you will read Mr. Robson's explanations upon this matter, at page 185, you will find all you desire upon this point.

CLIANTHUS PUNICEUS, BRUGMANSIA, VERONICA SPECIOSA (*A Two Year's Subscriber*).—Neither of the three plants we should call good plants for a warm sitting-room; the fine green foliage of the *Veronica speciosa* makes it the best of them, as this can be placed out-of-doors on a showery day, should its leaves be dusty, and it can be taken in again in the evening as clean as ever; besides which, it will endure for years to be pinched up in a small pot, and kept alive with a little water occasionally. The *Clianthus puniceus*, of which you have enclosed a leaf, appears to be eaten up with the red-spider, which this plant is very subject to. It is a half-hardy, rampant-growing plant, where it has room, light, and air to go a-head. In your sitting-room it must be a prisoner for want of light and air. It does best when planted out in some large conservatory, either for training up a pillar or rafter. There it is at home, but it will almost do out under a warm wall with a little winter protection. The *Brugmansia*, or, as it is called, *Datura*, is an odd clumsy-looking plant for a close warm sitting-room. It is true that this is not the season for this to be looking gaily. We should be careful not to over-water it. Like the preceding, it needs more light and air.

CUCUMBER FORCING (*G. B. C.*).—Cucumbers in the middle of March, or sooner, may be had where a well-regulated heating apparatus exists, and your pit seems very well adapted for that, provided you can command the necessary amount of heat, both bottom and top. The latter, being easiest attained, must not be allowed to range above 70° for cucumbers, and a certain amount of humidity given to it by placing vessels of water in such a way as to intercept the currents of dry heated air on its way into the pit or house; or, if the pipes be open and exposed, vessels standing on them will easily effect that object. In raising cucumber or melon plants, a rather brisk bottom-heat is required, and that not too drying nor yet too humid: at the early period required for the fruit-plants you had better plunge your pots containing the seeds in some fermenting heap, and, just as the cotyledons are breaking through the soil, remove them to your pit, where the atmosphere is more pure; a little contrivance will enable you to give them all the available bottom-heat, about 80° or 85° not being too much—even 90° will do no harm, provided other things are favourable. Melon plants, to plant in your pit in May, may be reared in a dung frame prior to that time very easily; or they may be brought forward with the cucumbers, as at that period the seed vegetates, and the plants grow with less trouble than earlier.

WEEKLY CALENDAR.

M D	W D	DEC. 30, 1852.—JAN. 5, 1853.	WEATHER NEAR LONDON IN 1851.				Sun Rises.	Sun Sets.	Moon R. & S.	Moon's Age.	Clock aft. Sun.	Day of Year.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last twenty-five years, the average highest and lowest temperatures of these days are 42.5° and 31.4° respectively. The greatest heat, 56°, occurred on the 30th in 1833; and the lowest cold, 12°, on the 3rd in 1827. During the period 107 days were fine, and on 68 rain fell.

THE IMPERIAL PAULOWNIA.

(*Paulownia imperialis.*)

This large-leaved tree is now well known in our gardens, and is hardy in the southern districts of England. It was first discovered by Thunberg, in Japan, where it rises to thirty or forty feet; he named it *Bignonia tomentosa*, but it does not belong to Bignoniads, as is currently believed, and as we shall presently show. Dr. Siebold was the next European traveller who found it, and brought home specimens of it, from which it was described by him and Professor Zuccarini, in their "Flora Japonica," and the name they gave, and which it retains, is in honour of the name of the Hereditary Princess of the Netherlands, who was daughter to the Emperor of Russia. It was first raised from seeds, in the Garden of Plants, in Paris, in 1834, by M. Neuman, who received them "from a person to whom they had been sent from Japan in little porcelain pots." Out of this consignment only one seed vegetated, and the plant received greenhouse treatment at first, as did the first Larch-trees that were introduced into Scotland, by the Duke of Athol. As late as 1840, M. Neuman could not determine whether or not his seedling from the porcelain pot was the same as the plant represented in the "Flora Japonica," and there was not a second plant of it then known to be in Europe. So that Dr. Siebold was not he who first introduced *Paulownia*, as is generally supposed.

When the tree seeded at Paris, in 1842-3, it was discovered, from the nature and formation of the seed, that the tree belongs to the Figworts (Scrophulariaceæ), and not to Bignoniads, to which it is still referred by some writers. The error is easily accounted for, from the fact, that there is

nothing to distinguish the one from the other in the formation of the flowers. The real difference in the kindred orders being found in the seeds. Thus, the popular English name of *Foxglove-tree* is botanically correct, in addition to the good idea it gives of the flowers which are produced from the end of the branches in close panicles or thyrses. They are as wide in the mouth, but not quite so long as those of the Foxglove, and of a greyish-violet colour, with an agreeable fragrance. The nearest affinity of *Paulownia* is with the *Wightia* of Dr. Wallich, in the same section of Figworts as the Pentstemon. The *Paulownia* was first figured in this country, in 1841, in Mrs. Loudon's *Ladies' Magazine of Gardening*. It was well represented in *Paxton's Magazine of Botany*, in 1842, but the first from English-born flowers is in the *Botanical Magazine*, t. 4666. In 1843, it flowered for the first time in England, in the greenhouse of Mrs. Wray, of Cheltenham, who sent specimens of them to the writer. But it was at Claremont, we believe, that it first flowered in the open air. In the system of Linneus it belongs to the second order of the fourteenth class, *Didymia Angiosperma*.

The Bishop of Exeter, in whose grounds at Bishopstowe, near Torquay, it has bloomed, describes the fragrance as "violet-like," but that the tree, as in the *Glycine*, loses much of its beauty by producing its flowers before its leaves.

B. J.

Propagation and Culture.—This fine tree is just as easily increased as are potatoes; and something in the same way, by thick slices, or short pieces of the roots, without the trouble of looking for eyes; and they will grow in any kind of earth, from stiff hard clay to the poorest sandy soil. While it is in a young, small state it is very liable to be much cut by frost: hence the reason why we see so few of them grown as fine standards, with ten feet or more of clear, straight stem; although it may be made to make a growth of ten feet in one season. An English gentleman, writing from Paris, in 1841, said that he had seen a growth of it made that season to the extent of fourteen feet; and from him I had the first plant of it. If any one wishes to have this tree as a low spreading bush, he has only to plant a small specimen in good rich soil and let it take its chance. It is naturally of a very spreading habit, and will extend a long way, carrying immense leaves; and I fear that is all that it is good for in most parts of this country. At any rate, give it the same treatment as Rhubarb, planting it in low sheltered situations, and cut it down to the ground the first two years, and it will produce leaves quite as large as an ordinary rhubarb leaf. That is just how I would manage it for a small garden. But for a standard, I would endeavour to get a good clean stem as long as possible before I would allow it to spread. The quickest way to get such a tree would be to begin with a strong plant from a nursery, to plant it late in April, in a sheltered, warm place, near a wall or building, and in a pit filled with the richest stuff or compost about a garden; to let it grow there three years, but for the first two years to cut it down clean to the ground before the frost, and in the third season to confine the growth to one stem, and not to let that stem branch; then, before the frost, to tie this growth up to a strong pole, and to thatch it with straw for that winter. Next spring, remove it to a dry, poor soil, and open situation. D. BEATON.

SHOULD it be proved, by further and more accurate experiments, that if the leaves of root-crops are cut off before those roots have arrived at maturity, and that, notwithstanding such removal of the leaves, the roots will go on increasing in size and nutritious constituents equally with other roots of the same crop from which the leaves have not been cut off, then will a heavy blow have fallen upon some of the opinions hitherto maintained by vegetable physiologists. It will be a heavier blow to those opinions than to the botanist, this discovery of the transmutation of *Ægilops* into Wheat, for it comes upon us like a thunder-clap, and is in direct opposition to laws which we have been compelled to live under now nearly fifty years; whereas, every schedule and clause of the law of sports and crossings have been critically canvassed over and over again, and even pushed much farther than M. Fabre has done, but without actual proofs, like his.

Two specimens of the Swedish Turnip were on the table at the Horticultural Society's last meeting, not quite so purple, perhaps, as Mr. Skirving's variety, but as fine specimens of size and texture as ever. Mr. Skirving exhibited in London. The whole tops of them were cut off down to the quick last September, and the wounds were now healed over; these turnips, therefore, could never push another leaf from the crown; but several eyes below the crown pushed and made a few leaves. They were not of a size, however, to give any support to the bulb; they were rather sprouts, sucking from, rather than adding substance to the bulb, according to our present ideas. That part of the lecture which referred to this fact was listened to with intense interest. It began by telling us that the Rev. Mr. Smith, author of "A Word in Season," was a scientific farmer; that his land was stiff, and not well-suited for experiments; but that by striking at the roots of popular notions, and following out notions of his own, results were obtained as far beyond present opinions as his plans were different from common practice; that his turnips, last year, after cutting the tops off as early as the tops of the two before us were cut, the yield was twenty-seven tons to the acre; that he could not get on the land this autumn to ascertain, by actual weighing, the positive weight of the present crop, but that he guessed it run from twenty to twenty-four tons per acre; that these turnips are in drills five feet apart, and a crop of early potatoes was got from the intermediate spaces before the leaves of the turnips spread out to cover the ground; that after lifting the potatoes, the middle spaces were deeply trenched, but only taking a small quantity of the new-broken ground to the surface; and, lastly, that before the leaves met and got crowded over the trenched parts they were cut for a green crop, and that the cutting of them did not hinder the turnip from swelling and getting heavier.

After the meeting, the philosophy of all this was canvassed, and the question was asked—Why should the skin of a turnip, exposed to the full influence of the sun and air, at a certain age, not be able to assist and finish the growth, seeing that an apple,

or a gourd, has to do as much? Why not, indeed! You seldom read or hear of an experiment or invention without its suggesting another. And why should we not have under-ground turnips, like carrots and parsnips, to get rid of the "strong, turnipy flavour" peculiar to the garden turnip? The "disposition" to sport in this direction has often cost the farmer more than his share of the "burden" of this heavy country: we allude to the "bunch of keys," the "fingers and toes," and the "forks and tails," into which the turnip "runs" every year.

We must declare our opinion, however, that, at present, the experiments of the Rev. Mr. Smith, and of others, do not prove that turnip bulbs will increase in size and nutritious constituents after their leaves have been cut off. They prove no more than that the leaves may be so cut off at the concluding time of their growth, and that the bulbs remain well-preserved in the soil. Now, did we not know all this before? Have not gardeners, for years past, cut their carrots and parsnips down into the quick, and found that they were preserved better than by any other mode?

It is quite true that fruits will improve in colour and flavour after they have been gathered, but they must have attained their full growth previously; and certainly, after being so gathered, they never increase in weight, nor even if left on the parent plant after this is denuded of leaves. Again, if a Peach, or other fruit, is on a branch from which all the leaves fall off beyond it, that fruit remains stunted and deficient in flavour, or perishes entirely.

In conclusion, we advise our readers to suspend their judgments until experiments more numerous and much more accurate have been tried. Let us have rows with their tops cut off alternating with rows from which the tops are not cut off. Let us have some of the tops cut off at the end of August, and some early in September, *before* the bulbs have completed their growth in size. If in such cases the bulbs go on not only to increase in size, but to increase in nutritious constituents also, as much as do those on which the usual amount of leaves have been left, then will it have been proved that leaves are not essential for bulbs in the concluding stage of their growth; and gardeners, in future, gratifying their praiseworthy love of neatness, probably may cut off the leaves of Crocuses, Tulips, and the like, when their bloom is over, without heeding the warnings of physiologists and "such small kine."

COVENT GARDEN.

ON the morning of Tuesday, the 21st inst., at an hour when half the population of this northern hemisphere were comfortably wrapt in the arms of sleep, we were wending our way to Covent Garden Market. It was an early hour; such an one as, fortunately, we have little experience of in this dark, humid season; but, being anxious to furnish our readers with some account of this great mart during Christmas week, we encountered the difficulties of the undertaking, and after a walk of

some three miles, we reached the place about half-past four or five o'clock. It is curious to traverse the roads and streets of London at this early hour. Where, twelve hours before, all was life and bustle, din and noise, now a calm, still, sepulchral gloom pervades the whole. But as we draw nearer our object of attraction, we hear and see approaching signs of life and activity, which gradually increase till we find ourselves in a perfect bee-hive of hum and industry. Every approach to the market is literally stemmed with waggons, carts, vans, donkey trucks, wheelbarrows, and every description of wheeled vehicle it is possible to think of. These are being laden with the market produce, to be again conveyed to the shops of town and suburbs. For many miles some of these vehicles have travelled to be there at the market hour; some even far in the country, where the very vegetables were grown they have come to purchase; for, as the gardeners never sell anything elsewhere than in the public market, a neighbouring greengrocer may have to repair some miles to Covent Garden to purchase the cabbages he has watched growing from the windows of his own house.

Having now made our way right into the centre of the throng, the sound that met our ears was "Misle, Misle, Misle-to-o-o-oe!" "Holly, Holly, Holly-o-o-o!" shouted in a noisy bawl, which terminated something in the way of what musicians would call a *soprano* part, but certainly far from musical. There were many waggon-loads of both. The former chiefly from Gloucestershire and Bucks, and the latter from Surrey, and the suburbs of London. As regarded the Mistletoe, we had no doubt the former proprietors of it were right glad to get rid of it; but the Holly called up other thoughts and recollections, and carried us back to six years ago, when spending a few days in the country during the Christmas week, we looked out one morning and saw two handsome hollies, each twenty-five feet high, completely bare, with no vestige of leaf or berry, except a sort of mop which had been left on the top. The evening before, when we last saw them, they were the handsomest pair in all the country for many miles round, feathered to the very ground, and rising straight as an arrow, as if they would shoot far away up into the blue sky; they were covered with a perfect shower of bright coral berries, and therein lay the temptation. Great was our grief, and great and numerous were the invectives we poured out on the villanous depredators, but they were miles away by this time, and very likely enjoying the fruits of their ill-gotten prey. How many shrubberies have been damaged and demolished during the past week it would be difficult to reckon; but we feel assured some of our readers could tell of a few, and of many a handsome holly shorn of its beauties. These wanton Vandals do not restrict themselves to cropping and trimming, but in many instances entire trees are borne away. We observed many specimens of handsome well-grown pyramidal trees, from eight to ten feet high, which had been cut off close by the ground, sold for half-a-crown and three shillings, which it must have taken many years to grow. Besides

the Mistletoe and Holly, there was a considerable quantity of Laurustinus, common Laurel, and Yew. Spruce Firs, for German trees, were also in great abundance, and exhibited a perfect forest of little sombre mountaineers.

VEGETABLES.—The supply of vegetables has been unusually great, which is attributable chiefly to the mildness of the weather bringing everything in at once; the consequence is, prices have been rather dull, and sales heavy. SAVOYS were making 1s. per dozen. GREENS, that is Coleworts, which are getting unusually large and coarse from the state of the weather, realised 2s. per dozen bunches, and when a quantity was taken, such as ten or twelve dozen, they were done at 1s. 9d. BROCOLI was very plentiful, more so than it has been for some time. One grower alone had as many as seventy dozen bundles. Now each of these bundles consists of from six to eight heads, according to the size, but taking the average at seven, this would give 5880 heads of Purple Brocoli supplied by one man. These made 6s. per dozen bundles, or 7d. for a single one. CELERY was also very plentiful, and made from 6d. to 9d. per bundle. ONIONS very fine, 3s. per bushel. PARSLEY, 2d. per bunch. POTATOES continue plentiful, and realise from £5 to £7 per ton. There have been a few parcels of SEA-KALE offered during the week, which were sold at from 1s. 6d. to 2s. 6d. per punnet, according to the quality, some of it being very weak and small. We observed also one or two bundles of RHUBARB. These last articles were, of course, both forced, and were of home growth, not imported, as a correspondent says his gardener would have him believe. We thank our correspondent for that communication, which shall form the subject of a few remarks on a future occasion.

FRUIT.—There has been a good supply, but not a very brisk demand for APPLES; that is, not such a demand as the salesmen had made up their minds to expect. Baking sorts made from 4s. to 7s. per bushel; and dessert, from 6s. to 10s. 6d. We observed some fine handsome parcels of the old *Royal Russet*, which realised the latter price. *Blenheims* and *Wellingtons* made 7s. 6d. to 8s., and small *Golden Winter Pearmain*, 3s. There still continues a good supply of *Newtown Pippins* and *Lady Apples*, and there have been several arrivals of the old French dessert apple, *Reinette Gris*. In PEARS, we have only the sorts which have been enumerated in former reports.

PLANTS AND FLOWERS.—There has been a great show in this department. The CUT FLOWERS have been particularly fine and choice. They consist of *Camellias*, *Scarlet Geraniums*, *Epiphyllum truncatum*, *Azalea indica alba*, *Begonia coccinea*, *Chorozemas*, *Cypripedium venustum*, *Roses*, *Christmas Roses*, *Violets*, *Chrysanthemums*, *Euphorbia splendens*, *Chinese Primroses*, *Polyanthus*, *Narcissus*, and *Lily of the Valley*; the two last being forced. FLOWERS IN POTS, were *Erica gracilis*, *Mignonette*, *Chinese Primroses*, *Van Thol Tulips*, and *Cinerarias*.—H.

GOSSIP.

It happens to those of moderate income, almost as frequently as to the wealthy, that they are desirous to *transplant a large tree* to some more desired position. The plan of Brown, and its improvement by Sir Henry Steuart, are well-known, and equally so for the difficulties it involves. A more efficient and easy mode, it is said, has recently been invented by Mr. Stewart Mc Glashen, Sculptor, of Edinburgh; and the following report of its success has been sent to us. The experiment was conducted in the presence of a great number of gentlemen and practical gardeners.

"The tree first experimented upon was a slender sycamore tree, of fifty-three feet in height, and five feet four inches in circumference at the thickest part of the stem. The soil was exceedingly damp, from the heavy rain of the previous night.

"The first process of Mr. Mc Glashen is to lay down a frame of T iron—in this case ten feet square. He then takes cutters made of malleable iron, one foot broad, and three feet deep, or, with the head and neck, four and a-half feet. These cutters are driven, by a wooden mallet, into the soil to the depth of three feet all around, and, being inserted sloping inwards, they give to the enclosed mass the form of a square blunted wedge. A rod of iron is then laid along the top of the four rows of cutters, and extension rods going across the frame force the heads of the cutters apart as far as possible, and, consequently, cause the points to converge at the bottom. A clasp or gland is then put around the trunk of the tree, with a mat under it to preserve the bark. Two parallel beams are then laid across the frame and fastened to it with chains. The above constitutes the frame to be raised. The means of raising the mass is a carriage (which also serves the purpose of transportation) consisting of two strong common carts, one at either end, with bolsters raised above the axletree of both, and on which bolsters rest two massive parallel beams secured to them with strong bolts. The height of the beams from the ground is about six feet. They, of course, enclose the tree. The process of lifting is exceedingly simple—the whole being accomplished by screw power. The screws are four in number, and so arranged as to make the lift equal. They are made fast to the beams of the frame, and are worked by men standing on planks across the beams of the carriage. The frame and enclosed mass are slowly raised, and the tree, with gentle oscillation, moves erectly upwards. The tree may, it is evident, be raised without the use of guy ropes—the solid mass of earth effectually balancing the trunk and branches—but they were used on this occasion as an extra precaution. After about twenty minutes working of the screws, the tree was completely raised from the pit, the operation having been effected in an easy and gradual manner, and amidst tributes of admiration from all around. It was not the intention to remove the tree experimented upon, but the means of removal being exhibited and explained, all seem satisfied with the feasibility of the apparatus for the purpose. A strong case was shown for the enclosure of the ball of earth, when the tree is to be conveyed to any distance. In moving, the tree still maintains its erect position. The propelling power is, when horses cannot be used, by a winch in front of the foremost cart, and block and tackle; but when the way is clear, and the road good, horses will do the work safely and more expeditiously. The tree is lowered into the pit prepared for it on the same principle.

"The cutters, which are driven in around the root, may sometimes sever the more expanding fibres; but this, we understand, will rather insure new ramifications in its adopted soil than at all affect the health of the plant. In fruit-trees, in fact, this is a device resorted to for the extension of the roots, thus giving new vigour to the plant. From the excessive moisture of the soil on Saturday, the ball of earth was not removed in so complete a mass as might otherwise have been expected—the weight of the water dragging the mould not adhering to the root back into the pit, but still there was more than enough of the native soil of

the tree raised with it to insure its preservation; and the circumstances of the experiment were, in this respect, exceptional.

"It is calculated that, in this instance, the weight lifted was thirteen or fourteen tons; but the inventor and patentee confidently states that, by an enlargement of the apparatus on the same principle, he could lift almost any tree. The principal experiment being accomplished, the company were directed to another part of the policies of Cramond House, where a holly-tree, about fifteen feet high, was lifted by four large and broad spades, forming a case to inclose the root. A similar experiment, by smaller implements, was made on a gooseberry bush, while some smaller plants were expertly lifted out by two semi-cylindrical spades. In each case the plant was extracted with its native ball of earth. All this was done, and the party afterwards walked to Cramond House, within the short space of an hour and a quarter."

We think that there is no probability of the price of good *Shanghai fowls* declining. We think so, because such birds combine more good qualities than are possessed by any other variety. At present there is an increased demand for such birds of high quality. At Birmingham, Mr. Punchard sold a cock and hen for £25, and Captain Hornby sold a cockerel and three pullets for £30. The taste for them is not confined to this country; they are most highly prized at Constantinople; and a very few days since, at Southampton, a large pen of about thirty of these birds were shipped for Jersey, and another pen, containing a still larger number, for New York. The taste for Shanghai fowls rests upon a much firmer foundation than some fancied combination of colour, which yet would obtain an enormous price. For instance, it was reported that there would be shown at Birmingham some *White Polands with black crests*, and we know that a gentleman was commissioned to give £100 for the pen if they had been there. No such variety was exhibited; and the last specimens known to have been in existence, we are told, were in the possession of the Duchess of Cleveland.

The following is a list of the *Poultry Shows* of which we are at present aware. We shall be obliged by any of our readers sending us additions to the list, and giving the address of the Secretaries.

CORNWALL (PENZANCE), January 10th, and 11th. (*Secs.* Rev. W. W. Wingfield, Gulval Vicarage, and E. H. Rodd, Esq.)

DONCASTER, January 21st. (*Sec.* H. Moore, Esq.)

GREAT METROPOLITAN, January 1st, 3rd, 4th, and 5th. (*Sec.* W. Houghton.)

HONITON, January 12th. (*Sec.* H. K. Venn.)

TORQUAY, January 14th and 15th. (*Secs.* A. Paul, and J. C. Stack.)

SOME NOTES ON FORCING.

WISHING to make our remarks suitable, as far as possible, to the period at which they first see the light, we will now touch on those things in the order that will best suit the requirements of our readers; and since this popular periodical has enlarged its sphere of utility, there is little doubt of a considerable accession of readers who are in affluent circumstances, and who possess a miniature forcing-garden, wherein they desire to produce those garden delicacies which are every day becoming more accessible to society at large. In assisting this

object, it will be found that THE COTTAGE GARDENER has had no mean share, whether it be as to eatables or decorative matters: it has removed in its day no small amount of ambiguity, and, by tracing matters as far as possible up to first principles, so highly simplified every gardening process, that the owners of gardens may see at a glance whether things are progressing safely or not. It need scarcely be observed, that such adds much to the delights of a garden, and gives a confidence for increased exertions, and the outlay of more capital in garden structures, &c.

KIDNEY BEANS.—Although these may be obtained almost every month in the year, it is not expedient, in ordinary establishments, to attempt to obtain them before February, which may be accomplished by planting immediately. In order to direct the reader's attention to a due economy in the choice of objects for his glass houses, let us consider what conditions are requisite for the forcing and culture of this delicate vegetable. They are as follows:—

1st. All the light it is possible to obtain.

2nd. A temperature of air of 60° for the lowest.

3rd. A liberal amount of atmospheric moisture *ever present*.

4th. A position within a yard or so of the glass.

In addition to these conditions, let us add, that a slight bottom-warmth of 70° to 80° is a very desirable thing if obtainable, although they are very successfully cultivated in pots without it; when they are planted in the soil it becomes highly desirable.

In considering, for a moment, the matter of light, it may be observed, that kidney-beans are very generally placed by gardeners in rows, on the kerb-stones of pits or houses, or on the back shelves of pine stoves or early forcing houses. Where such places are already occupied they may be forced very successfully in frames or pits, especially if fire-heat is applied, and a slight bottom-warmth can be obtained. If fermenting materials alone are used, the forcer must not begin until Christmas has passed, or the probability is his exertions will be rendered futile by excess of damp in the atmosphere. The temperature of air quoted previously must be well secured—Kidney Beans are almost as tender as Cucumbers: they may endure more cold, but under such circumstances they cannot be rendered profitable. And now for culture.

Soil.—They love a soil rich in decayed vegetable matters, but, like a great many other subjects connected with both in-doors culture and the open ground, this is only a part of the question. A steady permanency of moisture at the roots of plants subjected to the capricious fluctuations of forcing houses during dull periods in December and January, is a thing of greater import than even that of manures. However, Kidney Beans *must* have a generous soil; and the stability to which we have adverted must be sustained by some sound loam in the compost. Again, as the season advances, and heat and light increases, so in like manner does an increase in degree of a sound staple become requisite.

For early forcing, then, let there be—a compost of loam, leaf soil, and old manure, equal parts; and, for an advanced period, equal parts loam, and the other two conjointly. Now, this is the gardener's soil generally, but let not our readers be daunted as to soils—almost any generous garden soil will answer very well, especially if somewhat dark in colour. One thing may be observed, and that is—kidney-beans love not raw soils full of fresh organic matter, and this points at once to the eligibility of any sound soils of a generous character, where loamy matters cannot be had.

Pots.—We think it the best plan to use five-inch pots for the first, and when the beans are become sturdy plants to shift them into seven or nine-inch pots; the latter,

although best, require much room, but then the plants are more productive. It is well to put five beans in each pot, and, when they are up, to thin to three; thus, by striking out any two alternate ones, the remainder will be a triangle; and the beans in triangles will—the pots properly placed—serve to economise space. They require but little water until the pots become filled with roots; indeed, they should not receive a drop from the sowing until fairly up, or they may rot; the soil, therefore, at sowing, must be moist, in order to avert the necessity of watering.

In all the stronger kinds the central shoot may be pinched, as in Cucumber plants; this makes them more bushy, and less inclined to ramble; but we doubt the practice with such kinds as the Newington Wonder, and it certainly causes the crop to be a little later. When the plants are in blossom the use of liquid-manure may commence, and, if applied very weak, may be used constantly. We prefer this practice to strong doses, alternating with clear water, which latter plan is fitful in operation, forcing the plant into an expanse of foliage which is an overmatch for the root when the hour of trial arrives. The chief culture henceforth is to see that they receive regular attention as to watering; to suffer them to go long dry is at once to check their bearing, if not to stop it. They must not, however, be kept wet by any means; a medium must be observed.

EARLY CUCUMBERS—THE DUNG BED.—It is now an excellent time for the majority of our readers to commence; by the time this goes to press we shall have reached the shortest day, a subject of rejoicing with most, excepting those who cannot pay their Christmas accounts. It is of no use people commencing the culture of this esteemed vegetable earlier, unless they can see their way as to plenty of warm manure. January, in the main, is a light month; and if the plants can be got above ground by about the second week, capital chances may be secured of cutting by the early part of March, which is pretty fair for ordinary cases. To this end, a body of fresh dung, equal to the bulk of the intended frame, must be immediately thrown together; shaking much of the droppings-out, as they make it too fiery and hasten its decay: the object being to preserve the texture of the bed as long as possible. But here a question arises: Do you make what is termed a seed bed? This is by far the best plan; and a little two-light frame, about forty inches wide, by seven feet long, is a most capital thing for rearing young plants in, both for early Cucumbers and Melons. A frame like this, made up in January, is admirably adapted for sundry propagation or rearing purposes for many weeks afterwards; and it will also serve to rear successive crops of both Melons and Cucumbers. By the use of a "seed bed," the permanent, or ridging-out bed, of course, need not be built so soon by three weeks, and it thus retains its power longer.

And here we may point once more to the necessity of a thorough working of the dung; without this the difficulty of culture will be much increased, as also the uncertainty in the issue. About four turnings must be resorted to, taking care that at each turning plenty of water is used, for this purifies as much as the air. Thus, a heap thrown together to-day, fresh from the stable door, may lie one week at first, then be turned, changing the interior to the exterior, and watering liberally. It may then lie about five days, and receive a similar turning; then another five—at this another copious watering; and again another four or five, and so on; and at the last turning, if tree or shrubby leaves are available, by all means add equal parts with the dung; this makes the best fermenting material imaginable, and it will endure twice as long as the dung alone; besides that, the heat is so much milder, that with ordinary care it can scarcely

burn the roots of plants forced on it. Care must be taken to blend the two materials thoroughly. In building the ridging-out bed, which should be five feet high at back, and four feet at front, we never fill the interior; but merely keep building the out-sides, and what is termed tying-in the corners—that is, adding extra there, in order to bind the whole securely. In doing this, a good deal will of necessity fall into the interior; and by the time the bed is finished, the middle is sometimes more than half-full. Thus there is plenty of room for soil, &c., and it is almost impossible for the plants to burn. We have found it a capital plan, in adding hillocks of soil, thus to proceed:—Place a very large fifteen-inch garden pot, or other vessel, on its bottom, under the centre of each light, the top or rim about fifteen inches from the glass; place it firmly, and fill it with brickbats, and throw a little straw or moss over the surface to keep the drainage secure. On these, and around them, the hillocks are placed, and we have found it impossible to burn the roots; good linings must, however, be sustained for very early forcing. Melons sown about the first week of January will be ripe about the second week in May; and for that purpose either the green-fleshed Egyptian, Beachwood, Bromham Hall, or Snow's, may be chosen. One of the best kinds in the kingdom is a sort grown by our old and esteemed friend, Mr. Collinson, gardener to the Marquis of Westminster, at Exton Hall; he calls it a green-fleshed Egyptian.

We think, for very early forcing, a compost of equal parts turfy loam, leaf soil, and mellow bog soil, excellent; and if the old leaf soil has some little rotten manure in it so much the better, and a little of the charred materials of the rubbish yard may be added. For Melons, it is probable nothing will ever excel a sound loam of a turfy character, and a twelvemonth old at least—that is to say, such as has been more than a year piled in the compost yard. Depth is the great thing with the Melon: the soil should average at least a foot to have them fine; indeed, on this, and on persisting in keeping down all insects by timely perseverance, and by keeping the vine thin from the very first, depends, in the main, successful culture. To say that they delight in a generous heat is a mere truism; but it may be observed, that pains must be taken to sustain a lively bottom-heat to the last, even with summer Melons. Cucumbers may be suffered to part with most of their artificial bottom-warmth in summer, but this scarcely suits the Melon.

Let us advise the early forcer to give his frames a good stoving with sulphur before use, and on the heels of that to apply a clay paint, well charged with fresh lime.

R. ERRINGTON.

BULBS.

(Continued from page 204.)

ANOMATHECA CRUENTA (Blood-coloured).—Of all the small bulbs from the Cape of Good Hope this is the easiest to manage and to increase, and it holds in bloom longer than any other bulb belonging to the Irids with which we are acquainted. From November to March or April, it may be laid by in a drawer in a paper bag, and if it is then potted in peat, or any light sandy soil, it will soon sprout and be ready to turn out into a south border, in patches, or as an edging, in May, where it will soon be in flower; and if the seed pods are destroyed as fast as they are formed, the roots will keep on flowering till the frost puts a stop to them. It seeds as freely as oats or barley. February is the best time to sow them in peat—you may sow them “as thick as hail,” and in May turn out the ball and divide it into four or six pieces, planting each piece separately in the

open border, and by the end of July they are in bloom. I have seen it come up in the borders, from self-sown seeds, as thick as grass. No frost will hurt the seeds, but I am not sure how much frost the bulbs will endure. If there was a good demand for it, there is no reason why it should not be increased so that it could be sold as cheaply as snow drops.

ANOMATHECA JUNCEA (Rush-leaved).—This is not a very desirable species; and I question very much whether it is an *Anomatheca* at all. I have known so many mistakes about bulbs, that I have very little faith in the characters on which they establish genera; yet the genus was founded on this very plant, which is quite a dwarf, with a rather delicate bulb and small lilac-coloured flowers. It must be grown in a pot and in good turfy peat with a sixth part of sand.

BOMAREA.—Beautiful as most of the *Alströmerias* certainly are, we know none of them, either in cultivation, or by dried specimens, that can at all vie in beauty and stateliness with some of the *Bomareas*, of which about fifty species, and many wild varieties, have been figured and described, although we have hardly half-a-dozen of them yet in cultivation, and none of these even second-rate, except *Acutifolia*, from Mexico. About a dozen years back, Mr. Pentland brought over three sorts of them from different situations near Cusco; but that seems to be too far south for much beauty in this genus; the best sorts being in a belt of country in Peru, a few degrees on either side of the line. I never heard the history of the large collection which Hartweg sent to the Horticultural Society, and which were lost at Carthagena; but, from the point where he crossed the Andes, and from the higher sources of the Magdalena, he must have met with some of them. Mr. Veitch has others gathered by Mr. Lobb; but hitherto they have flowered in winter, and not to Mr. Veitch's mind: and no doubt, as his name is up for the best new things, he will not risk the chance of giving disappointment, so he proves his things before he lets them out of his hands. If his *Bomareas* are really winter-flowering plants by nature, they will not do here, as they, all of them, ought to flower in the open air, and in dry weather, else their delicate tints are gone. After describing what few of them we have in cultivation, I shall give the names and localities of some of the best and most desirable to procure, in the hope that some one will lay a train by which to get them down from the mountains to some ports in Peru, and thence home by the Panama route. In Chili they call the whole tribe, *Flos Martini*, “St. Martin's Flower.” Perhaps the same in Peru, and if so, that would be a hint to any of the natives for looking after them.

BOMAREA ACUTIFOLIA.—This is the best of those we have in cultivation. In good, rich soil it twines up ten to twelve or fifteen feet, and flowers in drooping clusters from the ends of the shoots. When the young shoots are about six inches long, in the spring, if the tops are broken off, they will branch better, rise less high, and flower more abundantly. The flowers are nearly scarlet. It ripens seeds freely when trained against a wall, but the plants do not always come true from seeds; all the variations that I have seen are inferior to the species. The simplest way to train all of them is to drive a nail at the bottom of a wall, and to fasten a string or wire to it, fastening it again at the height of eight or ten feet, and if it gets but one turn round the bottom of this it will train itself for the rest of the journey; and if it is a mild season it will keep green to Christmas. It will not cross with any *Alströmeria*.

BOMAREA EDULIS.—The accent is on the u, but half the world put the stress on e. This is a West Indian stove plant, a native of St. Domingo. In the Botanical Magazine, and some other works, it is called *Alströmeria salsilla*, a very different plant from Chili.

The flowers are middle-sized, chiefly red, and the leaves are quite smooth. It is a scarce plant now.

BOMAREA HIRTELLA.—This is the second best species in cultivation, a native of Mexico. The sepals are red, and the petals greenish, dotted all over with red dots; it does not run so much as *Acutifolia*, but it is more hardy, growing up to a stake in the common shrubbery, as I saw it last October, and in flower, near Oxford, in the beautiful garden of the Rev. J. Lys. It seeds against a wall, but will not cross with *Acutifolia*, from the same country. It was first named by Sweet, and figured in his British Flower Garden. After that it was called *Ovata* in the Botanical Magazine; but *Ovata* is a nonentity, and must be expunged from our Dictionary. It goes to rest earlier, and rises later in the spring than *Acutifolia*; these are the two that would twine round for an edging to a bed of *Alströmeria*.

BOMAREA SALSILLA.—This is a Chilean species, and one of the oldest, being the third species which Feuillet brought to France, *Peregrina* and *Ligtu* being the others; but, by a strange oversight in the Botanical Magazine, *Ligtu* and *Salsilla*, out-door plants, were confounded with *Edulis* and *Alströmeria caryophylloides*, which are stove plants, and the error is handed down to this day in some collections. *Salsilla* is a very scarce plant; the flowers are purplish-red, the two back petals having a black spot at the bottom, and the lower petal a light spot. Like *Acutifolia*, it does not always come true from seeds.

BOMAREA SIMPLEX.—There are three varieties of this with reddish-pink flowers. They are Mr. Pentland's plants from Cusco, and they flowered out-of-doors, against a greenhouse, with Dr. Herbert, at Spofforth, in Yorkshire, but what became of them when his collection was dispersed I never ascertained. These are all the Bomareas that I know of in cultivation. Matthews, Tweedie, and Col. Hall, are our chief authorities for the best not yet introduced, of which the following are the chief:—

B. superba. Flowers large, orange and red, twelve in a head, and each flower nearly two inches long. Peru.

B. crinita. Flowers orange and red, on footstalks as long as those of *Cobaea scandens*, setting the flowers widely apart; they are longer and larger than those of *superba*, and ten in a head. It must be a magnificent thing. Peru.

B. crocea. This is figured in the Flora Peruviana, from "Chumpulla in the Peruvian province of Panama." It is saffron-coloured, and grows eighteen feet high.

B. pardina. Twenty large flowers on short stalks, making a superb head of yellow or orange flowers, spotted like a leopard, found by Col. Hall at a place called Patacocha, "on the western declivities of the Andes, at an elevation of 6000 feet." A splendid thing.

B. Patacoccensis. "Another magnificent plant," from the same locality as the last; flowers reddish-yellow, and thirty or more of them in a crowded head.

B. lutea. Flowers bright yellow (Col. Hall), by the road to Mindo, at an elevation of 9000 feet, "on the western declivity."

B. formosissima. Figured in the Flora Peruviana; flowers large, purplish-red and yellow, the petals richly spotted, and as many as eighty flowers have been counted in one head! It grows from ten to twelve feet high, "in woods near Munna."

B. Hookeriana. Petals deep orange; sepals red; one hundred flowers in one head! and leaves six inches long. From the province of Chacapoza, in Peru.

B. densiflora. In habit and colour like *Acutifolia*, and with nearly as many flowers as *Hookeriana*, and from the same locality.

Now, to say nothing of some most beautiful *Alströmerias* and *Collanias* that might be met with, and fifty more plants equally beautiful, that we know of only

from dried specimens, these *Bomareas* themselves would pay a spirited nurseryman to send out a clever man on purpose for them. Every one of them would outlive the winter with slight protection, or, what is just as likely, without any protection whatever. Their very names are circulated to-day for the first time among British, or even European gardeners, and how can we push for things we know nothing about.

BRAVOA GEMINIFLORA (Flowering-at-the-joints). This is a small bulb, and in looks is the nearest to an *Ixia* of all the Amaryllids. The bulb is solid like that of a crocus, and about the same size. From among its *Ixia*-like leaves, it throws up a jointed flower-scape, nine or ten inches long, flowering all the way up, two flowers at every joint, of the same shape and colour as the flower of *Watsonia meriana*, a dull red-tubed flower, but not more than a sixth part of the size. It is a native of Mexico, where it takes a wide range. Galeottu found it growing with *Sprekelia formosissima*. I had it from him, and I flowered and seeded it in an open border. It goes to rest all the winter, and will grow in any light soil. It does not appear to do well in a pot. I never see this plant without its reminding me of an item in the invoice sent with it—£48 for a stupid mule, which made a false step, pulled a huge Cactus out of a gorge, tumbled over a precipice, and broke his neck, yet the brute may be alive to this day for ought that I know. The British Consul in Mexico at the time could tell the tale better than I can.

BRODLEA CALIFORNICA.—This is a true *Lilywort*, and is hexandrous, or six-stamend, notwithstanding the views of Decandolle, which are followed in our Dictionary; the old genus has been split many years, and the species with three barren stamens are now called *Leucocoryne*. The present species is the newest of them. It was sent to the Horticultural Society, in 1848, by Mr. Hartweg, from "the mountains and plains of the Sacramento, where it is scarce." It is a very desirable hardy bulb, with pale-blue flowers, having a dark line up the centre of each petal and sepal. It propagates itself readily by offset bulbs from the old one, and it flowers in any good garden soil from July to October; but the great value of this plant is for improving the other species, on the supposition that it will cross with any of them. The Chilean section, called *Leucocoryne*, are the most difficult to keep, to flower, or to increase, of all the half-hardy bulbs. One of them, which I shall mention in its proper place, is so like this one in flower, and both are so like *grandiflora*, except in the relative size of the parts, that one can hardly believe they would refuse to cross. The constitution of this plant must be very similar to that of the Chilean species, judging from the nature of the two localities.

BRODLEA CONGESTA.—This is a North American species from the southern states, and may require, like *grandiflora*, some protection in hard frost, as does the *Atamasco lily*, from the same parts. This has a light blue flower, but is more dwarfish, and smaller in all its parts than *grandiflora*. The three are not well adapted for pot culture, owing to their way of growth, like the *Ixiolirions* of Syria, and our own *Squills*. These, their allies from America, look better in borders, and are less liable to mishaps there than in pots. For a man to be able to grow a good collection of bulbs in pots, he would require to find out a part of the world where no one could get at him from one year's end to another.

BRODLEA GRANDIFLORA.—Notwithstanding the name, this flower is not quite so large, nor of such strong substance as *B. Californica*. In other respects it is much like it, and it is equally hardy, and flowers in summer. They all rest in the winter, and prefer a light, deep sandy-soil, if it is fresh, and if not, leaf mould is the dressing for them. In very hard weather the border should be covered with saw-dust, tan, or coal ashes, and,

what is of much more consequence, means should be at hand to throw off the wet. Much wet is more injurious to half-hardy bulbs than cold and frost when the soil is dry, and placing clean sand about them is the best preventive.

BRUNSVIGIA.—All the true *Brunsvigias* form a very natural section of *Amaryllis*, with which they are now known to interbreed, establishing identity of kind. They have all very large oval bulbs with a short neck; their leaves are very broad and recumbent, or lying flat. They all flower in the autumn, after resting three or four months, and before the leaves come, and all of them grow with us from October till May. *Amocharis falcata*, the *Brunsvigia falcata* of our Dictionary, and of others, differs essentially from the true *Brunsvigias*—in resting four or five months in winter, and in not flowering until the leaves are full-grown. Our *Brunsvigia cilialis*, *disticha*, and *toxicaria*, belong to a very different section, if not a true genus, called *Buphane*; and *Brunsvigia coronica* of our Dictionary is an *Amocharis*, and cannot be determined from *A. falcata*, unless the two were in flower together. *Coronica* is figured in the Botanical Register, and called an *Amaryllis*, which is very probable; but the fact has not been yet proved; at least not to our satisfaction. *Buphane* can hardly be an *Amaryllis*; yet we have seen so many barriers of generic distinctions broken down in these plants, that the wisest cannot say with certainty which is, and which is not, a proper limit to the genus, in the absence of natural experiments in crossing them. Therefore, in treating on all the species under *Brunsvigia*, as they stand in the Dictionary, I shall notice their sections within brackets, and explain their cultivation separately under each species. D. BEATON.

(To be continued.)

SOFT-WOODED, WINTER-BLOOMING, GREENHOUSE TWINERS.

TROPEOLUM LOBBIANUM.—Most of our readers are well acquainted with the Indian Cress family, from the hardy annuals, commonly, though improperly, named *Nasturtiums*, with their large showy flowers, and large round, pellate leaves; to those more tender, tuberous kinds, such as *tricolorum*, in which the flowers are beautiful and well seen, though small, and more or less hand or finger-like divided. The species I have named above was introduced, some eight years ago, by Mr. Lobb, from Columbia, and may be said to hold a middle place in the group, the plant, when vigorous, having large pellate foliage, and, comparatively speaking, small flowers. What should be aimed at, therefore, is to make its reddish-orange flowers as numerous, and the foliage as small as possible. For real usefulness this plant is second to none of the family, while, if a few simple matters are kept in view, it will stand roughish treatment, and thank you for it too. As an ornament for the greenhouse, in winter, few things will beat it. I was delighted with it several years; and though, like many other good things, it has been set aside for a time, I intend to give it a niche next season. To save annoyance, I may mention, I never could please myself with it, unless for winter and spring blooming, though I have tried it many ways out-of-doors during the summer; planting it out in the open ground, so that it might run up a post, or along a chain; potting it in poor, sandy soil, and even cutting the roots to prevent luxuriance, and cutting off whole masses of the larger foliage; but do what I would, the few flowers that showed themselves, long-stalked as they were, were too much hid by the luxuriant foliage. Under such treatment, however, it showed itself to be a hardy annual, as the seeds that

were self-sown came up as vigorously the following season as the common *Tropæolum major* generally does. I might say, therefore, that the plant is truly valuable only for winter-flowering.

“How must I treat it best for that purpose?”—It is easily propagated. Seeds sown in a slight heat in April or the beginning of May, will vegetate freely. Cuttings taken off about the same period will answer equally well, or rather better; but, however raised, the plants will soon become vigorous enough. If raised from cuttings, place the cuttings in sandy soil, round the sides of the pot; and place it in a shady place, under glass, and in a little extra heat, if previous to June. You may cover with a bell-glass, but take it off partially, or wholly, at night, or the succulent shoots will damp. As soon as rooted and growing, whether plants or cuttings, let them be potted off in four-inch pots, kept close and warm, to encourage growth, and shifted into a size larger pot, as soon as the first is filled with roots, and keep close again, until growth is freely progressing; and then give air, gradually at first, and then freely; until by the beginning of August, at farthest, the plants may stand in the open air, fully exposed to all the sunshine they can get. Previously to that, however, they should have received their last shift. A pot eight inches in diameter will be large enough to fill a globe trellis three feet high and two feet in diameter. To mount a column, and span a wide arch in a conservatory, a pot nearly double the size would be necessary; for intermediate sizes act accordingly. The soil during the whole growing period should be light sandy loam, with a dusting of leaf mould and charcoal. When the luxuriance is gone, and the plant is showing profusion of bloom, manure-waterings, or a good top-dressing of old cow-dung and charcoal will be gratefully received.

Whether grown for an arch or a trellis, one shoot will always be better than many. If for an arch, it should be taken up a stake, and then on a cord fastened to the top of a wall or pole, and then moved and fastened to the arch in September, and the shoot stopped when it has nearly filled the allotted length. Manure-waterings, and removing by degrees the larger leaves, will cause the side-shoots to grow freely; and then these dangling a yard in length, and covered with bloom, the leaves being little larger than a sixpence, few things are more beautiful. One of the finest things I ever saw in this way was produced from the *Maurandya Barclayana*, but then, so grown in a house, its beauty was gone by August, when it, and such other things, might well be succeeded for three or four months by this *Lobbianum*. As a trellis-plant, however, it will be chiefly used. By the time its one shoot has reached two feet in length, begin to train it round, each turn being about six inches from another, having the point of the shoot looking upward to encourage growth. When thus it reaches the top of the trellis, let it be trained a little back again, and then stop it. Ere long, not only from the base, but all over from the axils of the leaves, young shoots will peep; plenty of water must then be given, and full exposure. At short intervals, a number of the larger leaves should be removed. Do not be afraid in the matter, as we are not thinking of getting larger roots, but a profusion of bloom, with smaller foliage, and with proper watering, there is enough of succulence in the stems to prevent all danger if you do not go to great extremes in thinning. The plants should be housed by the end of September. During winter you will see the propriety of removing at the right time the larger leaves, as for several months you will scarcely see a green part, owing to the dense thicket of blooms. The flowers are useful for nosegays, owing to the great length of their flower-stalks. I have deemed it right to chronicle these little matters, as though the plant is of little pecuniary

value, few things will beat it in winter when thus managed.

As I have got upon this genus, I may just allude to two more.

TROPEOLUM PENTAPHYLLUM is one of the hardiest of the tuberous-rooted kinds; a native, I believe, of Monte Video. It blooms freely out-of-doors from June to November. On this, the 20th of December, it is still in fair condition, running along a wire between two posts. Like most of the tuberous kinds, you cannot predicate with certainty on the time of its growth. Instead of starting in spring, you will find that they sometimes begin to shew themselves in July, and later; and by keeping them cool and dry, the period of starting will always be retarded, and in course of time get into a habit. Now, I mention this, because all late-starting bulbs of this species will bloom nicely during the winter, and profusely in early spring, along the rafter of a greenhouse, or round a large trellis, if it has *plenty of light and air*. The soil, however, must be open and rather rich if in a medium-sized pot. I have seen them thus treated keep beautiful for the most part of a twelve month.

TROPEOLUM TUBEROSUM.—A correspondent, lately speaking of the pretty *nice* tubers he had so successfully obtained, but which our English epicures are very careless about, added, that he would like much to know how to bloom it. Now I question if ever it could be made to rival *Lobbianum*; but there is no saying what it might do, if it had house-room, and plenty of it, in *winter*. Even when I have started the tubers early, I never could get the shoots to show bloom until *late* in the autumn. I recollect, that when first introduced, it was mentioned as a plant that grew three feet in height; but three yards, or even three to that would be nearer the mark in our moist autumn climate. I have been rewarded with a fair portion of bloom *twice*, in both cases late in autumn, in such a mild season as this; once, in a greenhouse where there was no heat, and once against a wall. In both cases the blooming was arrested by frost in November. The plant against the wall, as well as that in the glass case, was confined in a pot, and the soil was a little peculiar, nearly one half sandy loam, the rest *roughish gravel*.

MANETTIA BICOLOR.—This, with its red and yellow tubular flowers, is a gem of the first water. It generally blooms from November to April. A warm greenhouse is the place for it in winter, such as will suit progressing Cinerarias and Geraniums. A cool, airy greenhouse, such as would suit Heaths and Azaleas that you did not wish to hurry into bloom, would be too cold for it; a common plant-stove, far too hot. The same remarks apply to most of the family, especially during their blooming periods. This is, therefore, best when trained round a trellis, so as to be moveable; one, two-and-a-half feet in height, will give you means for a nice little plant. It is also one of those things for which a flat trellis, I mean an upright one-sided one, may be tolerated; as the blooms look very nice when thickly studded on such a surface. The *soil* it likes is formed of equal portions of heath mould and loam, both fibry, with sand and charcoal to keep it open. Manure-waterings, if weak, may be given with advantage during the summer, when the plant is making its growth. When standing in the greenhouse in winter, a double pot will be useful, to save the roots from being at any time suddenly chilled. The water used should, for that period, be always warmer than the atmosphere of the house. If there is no other convenience, when the plant has done flowering, it should be pruned considerably, and be kept in the closest and warmest end of the house, until growth is freely progressing, when it must be gradually exposed to full light and air. But, where there are hotbeds, or forcing-houses, the neatest plants for winter use are obtainable from cuttings struck

about March. The following is the routine for such plants. Choose firmish side-shoots, about three inches in length; and, as second best, the points of other shoots that are getting rather firm; insert them in sandy soil, with silver sand on the surface; water, and when the leaves are dry, place a bell-glass over them, and set the pot in a mild hotbed; shade from sun; in a week, plunge the pot, if bottom-heat is not above 75°; ease the bell-glass at night with a pebble, to give a little air, making it close in the morning; pot as soon as they root, and as soon as the small pot is filled, pot again, and keep in the hotbed; top the shoots, that you may multiply them; an eight-inch pot will grow a nice plant; by the middle of June take them to a cold pit, keep them rather closish until August; expose them freely to sun and air in September; give less air towards the middle of October; by the end of the month remove them where they can have a dry heat, or, for want of a better, to the warm end of a greenhouse.

R. FISH.

THE CHRYSANTHEMUM.

(Continued from page 224.)

HAVING given in my last a few hints on cultivating this favourite flower, I now proceed to give a selected list of the best sorts, such as will answer "Cato's" purpose, as well as of any other grower who wishes to make addition to his stock. The list includes good old kinds, as well as more recently raised ones. I went purposely, at the time they were in bloom, to see a large collection, in order to be sure of selecting good varieties.

LARGE-FLOWERED CHRYSANTHEMUMS.

Annie Salter, deep yellow; fine form, very double; the best of all yellows.

Barbette, rosy-pink; neat flower and good form.

Beauty, a lovely blush colour; finest form, large flower; one of the best.

Bixio, violet-carmine; good form, and rich colour.

California, golden-yellow; very fine.

Chancellor, clear sulphur; fine form.

Christine, light rose; very double, fine form; a good show flower.

Clustered yellow, very double; a tasselled flower of a fine colour.

Cloth of Gold, golden-yellow; extra large; a fine show flower.

Comte Rantzan, dark bright crimson; excellent shape; a good show flower.

Cyclops, fawn and buff centre; good.

Defiance, clear white; extra form, large and very double; fine show flower; has probably won more prizes as a white than any other variety.

Dupont de l'Eure, light carmine, shaded with orange. This is a fine variety.

Duke, a pleasing blush colour, and a fine show flower, with good properties.

Etoile de Versailles, blush-white, tubular florets; very double, and one of the latest bloomers.

Formosa, clear white; fine form; a good show flower.

Fleur de Marie, beautiful clear white, anemone-flowered; fine form; one of the very best of its class.

General Rochambeau, light claret; good form.

General Marceau, light blush; a fine show flower.

Gluck, bright golden-yellow, anemone-flowered; very double, large, and a good show flower.

Goliath, a large white flower; well adapted for exhibition.

Hengist, rich dark orange; fine form.

Hecuba, salmon, shaded with orange.

Jenny Lind, pure white, incurved and very double; extra good.

King, light rose; a beautiful colour, very double, and a fine show flower.

Lady Talfourd, pure white; very large.

Lavinia, a large flower, of a rosy-blush colour.

Lucidum, good white, incurved; a fine show flower.

Madame Camarson, red-crimson, tipped with gold; a rich-coloured flower, very double, and first-rate form.

Madame Godereau, light bronze, very double; a fine show flower.

Margaret d'Anjou, dark; a fine show flower; extra.

Miss Kate, a delicate lilac colour; fine form; extra.

Nancy de Sermet, a clear white, very double anemone-flower, rivalling *Fleur de Marie*.

Ne plus Ultra, large flower, of a pleasing lilac-peach colour.

Nonpariel, rosy-lilac; large in size, and excellent in form.

Peruvian, dark golden colour; a fine show flower.

Pilot, large flower, of a beautiful pink colour; a good show flower.

Pio Nona, orange-red, with golden tip; a rich, fine flower.

Polycete, bronze-orange, a large semi-double flower, long petals; fine.

Phidias (New), very distinct, from the old *Phidias*; rose shaded with red; very large.

Queen of England, blush-white; a splendid large show flower.

Queen of Gypsies, deep orange-red; large and fine.

Rabelais, carmine and yellow; extra show flower.

Sydenham, light carmine-red; a good show flower, with excellent properties.

Temple of Solomon, fine yellow; a good show flower.

The Warden, deep orange, with a darker border; a large, incurved, extra show flower.

Vesta, clear white; good form; fine show flower.

Vulcan, fine dark crimson.

Zoe, rosy-blush; very large.

SMALL-FLOWERED, OR POMPON CHRYSANTHEMUMS.

Adela Renard, pale purple; fine form, and very double.

Argentine, silvery-white, very double, free flowerer. In my opinion this is the best of all the Pompones.

Asmodée, bronzy-red; fine form, but rather flat in the face of the flower.

Autumna, bronzy-buff; double and constant; good.

Bouton de Venus, rosy-white; double, and free-bloomer.

Circe, blush-lilac; neat, double, and good form.

Cybele, golden-yellow; fine.

Elize Miellez, deep rose; fine form; very double.

Fenella, bright orange, rather small, but good form.

Fritillon, yellow; good form, medium size; extra.

Harriet le Bois, lilac centre, with purple tops; good.

Jonas, a fine-formed flower, pale lavender.

La Sapajou, orange and red, anemone-flowered, with smooth petals; double, and good form.

Madame de Contade, shaded blush; fine form.

Madame le Comtesse de Vatry, light purple, broad petals; fine form, and very double.

Nonsuch, light yellow, very double; excellent form.

Nini, buff, with white centre; neat, and very double.

Perle de Brezil, white; fine shape, very double.

Pompon d'Or, bright golden-yellow; double, and finely formed.

Renoncule, rosy-carmine; very distinct and fine.

Roi de Liliput, rose, with carmine edge; double, and of an excellent shape.

Sacramento, dark yellow; one of the best.

Stella, deep yellow; free bloomer, very double, much in the form of a Ranunculus.

T. APPLEBY.

CONIFERÆ.

(Continued from page 207.)

LIBROCEDRUS.—A genus established by the late Professor Endlicher out of the Arbor Vitæ (*Thuja*). Dr. Lindley tells us, in the Horticultural Society's Journal, that the Professor's reasons for so doing are "mainly on account of the scales of the cones being pressed face to face, instead of overlapping at the edges; he also relied upon some difference in the seeds, which appears to be of less importance, and which are not exactly as that lamented botanist supposed them." As this botanical distinction in the genus appears to be sufficient to the acumen of the learned doctor, I have adopted it in this list of Coniferæ, though no common observer could, by its habit alone, see a sufficient difference to separate it from *Thuja*. The name, too, is used in the gardens at Kew, and in all the nurseries round London, and at Bagshot; so that we may consider it fairly established.

LIBROCEDRUS CHILENSIS (Chilian L.)—A beautiful tree, attaining, in its native habitats, the height of forty feet. It is found in valleys amongst the mountains of Chili. It has a considerable resemblance to the common American Arbor Vitæ, yet is easily distinguished from it by its more silvery green, by branching more from the base, and often forming a more conical head. Seeds have been imported largely, and, consequently, plants are plentiful in the nurseries, especially in that of Messrs. Low and Co., at Clapton, and at Mr. Hosea Waterer's, at Knap Hill, near Bagshot. It is perfectly hardy in the south of Britain, and probably will be in the north also, if planted in a sheltered situation. As it is a most beautiful tree, it ought to be in every collection.

L. DONIANA (Mr. Don's L.)—This species is a native of New Zealand, and therefore requires the protection of the conservatory. In its young state it might be easily taken for a dense tree Lycopod. There are some fine specimens, four to five feet high, in the greenhouse at Kew. Here they are strikingly beautiful, from their bright, lively, green foliage and singular habit of growth. As an ornament to the conservatory there are few Coniferæ that surpass it in beauty. In its native woods it attains the magnificent height of seventy feet, and is useful as a timber tree, the wood being beautifully grained, close, and heavy.

L. TETRAGONA (Four-sided L.)—From South America. Dr. Lindley observes, that "this species bids fair to be a rival to *Araucaria imbricata*, and to be as hardy, for it comes from just below the snow line of the Andes of Patagonia, where Mr. Lobb found it in the state of a tree from fifty to eighty feet high." It is a magnificent evergreen tree, and, being likely to be hardy, will, when it becomes more common, be planted as largely as its rival the *Araucaria*.

PHYLLOCLADUS, a name derived from *phyllon*, a leaf, and *klados*, a branch. This is a small genus of singular trees, scarcely hardy enough to bear the severity of our winters; but they should have a trial in such counties as Devon and Cornwall, or perhaps against a conservative wall for a few years, till they become woody, and inured partially, and afterwards planted out in a sheltered situation, they might become more able to resist the cold. I have seen one species, the *P. rhomboidalis*, growing in the open air in the Botanic Garden, at Belfast, and was informed it had stood the winter there with scarcely any protection; but then the climate of Ireland is much milder, especially near the sea, than most parts of England. In that locality (Belfast) I saw Fuchsias twelve and fourteen feet high, with stems as thick as my leg, and apparently ten or twelve years old, quite bushy trees. Well may such trees as *Phyllocladus* live through the winter in such a climate. It is true the Fuchsia is hardy here also, but it only exists as

a kind of herbaceous perennial, dying down to the soil edge every ordinary winter.

PHYLLOCLADUS TRICHOMANOIDES (Maiden-hair-like P.).—This is another remarkable New Zealand tree, bearing some resemblance to the curious-leaved *Salisburia adiantifolia*, only the leaves are more divided at the margin. When young, the foliage is a blue-green; but as the leaves become old they become of a dark brownish-purple, giving the tree a most singular outlandish appearance. As a contrast in colour, as well as a great curiosity, the plant is worthy of a place in a large conservatory. Like most of the New Zealand trees, its hardihood, except in highly-favoured situations, is more than doubtful, and it is, therefore, safer to give it a gentle protection. A very interesting collection might be formed of trees and shrubs like this that would live in a glass-house without heat, but are not hardy enough to be entirely exposed. The only expense would be the cost of the building at first, the keeping them clear of weeds and insects, and a little attention to pruning, and thereby keeping them in form. Some day or another I will draw up a list of plants suitable for such a cold habitation. I am quite sure such a building would be useful, for more plants are spoiled by too much heat than many persons are aware of.

P. RHOMBOIDALIS (Rhomboid or Celery-topped P.).—This is the *P. asplenifolia* of Dr. Hooker the younger. It is a native of Van Diemen's Land. Like its co-species, it has a most singular appearance, and is a beautiful branching tree, found growing close to the sea-shore. It can only be called a half-hardy tree, requiring the protection of a conservatory, or a glass-house without artificial heat.

T. APPLEBY.

(To be continued.)

HOT-WATER versus POLMAISE.

SOME years ago, a warm controversy was carried on in our then existing gardening periodicals of the relative merits of the two modes of heating noted above. The advocates of the newly-invented system of heating by propelling currents of warmed air to circulate through the interior of the building, insisted that the sluggish warmth imparted by hot-water-pipes or tanks, tainted, rather than improved, the condition of the atmospheric air it acted upon; and though it supplied the necessary amount of heat, it was said to be more of a mechanical than of a natural kind. Against this imputation, the friends of iron and water pointed to the many instances in which the atmosphere of structures intended to be Polmaise was little more than a compound of smoke and steam, supplied separately or together, as the case might be; while, in some other cases, where these agents were kept under proper control, the heat supplied was, by certain wayward propensities of its own, all confined to one end, or other place of entrance; coupled with these evils was the extravagant use of fuel required to furnish heat from so limited a space as that from which it was, in the true Polmaise system, confined; this latter evil led to the apparatus taking the character of a "flue" (either long or short) entering or traversing the house; where such was done, the Polmaise resolved itself into nothing more than the old-fashioned "smoke-flue," about whose action our grandfathers knew about as much as we do. Various improvements, in the way of amalgamating the flue and Polmaise together, were tried with more or less success, and the latter plan itself became so altered in character, that its original inventor can hardly recognise it now as having any analogy with the "hole-in-the-wall," and "wet-blanket" mode by which he first introduced it. However, it must be admitted, that some of those hybrid contrivances, whereby the merits of the Polmaise and the smoke-

flue become united, act tolerably well; and, in some few instances, where good gardening skill is brought to bear in the matter, the production of such Polmaise-heated structures cannot be excelled by that of any other contrivance whatever; it is, therefore, only just to infer from such results, that the principle is a good one, but the practical details of working it out rather difficult. This, I believe, its most sanguine friends admit; since none, that I am aware of, have continued long in working order without something going wrong, or, it might be, an improvement appear feasible.
